From childhood, we hasten on to adolescence, the age of sex awakening and social restraint of the sex impulse, the premarital state Here we find susceptibility to, prevalence of and damage from venereal diseases greatest With syphilis causing one tenth of all deaths, producing 20 per cent of the inmates of our institutions for the insane (whose total population approximates the population of our universities), with gonorrhea as the chief cause of sterility and the principal contributor to the gynecologic wards of the hospitals, with its enormous drag on efficiency and industry—in combination, a group of diseases which in the height of the war took more men out of the line of battle than shot and shell and gas—and you have a field of medicine that largely sustains three specialties, gynecology, genito-urinary surgery and skin diseases, and, in addition, generously contributes to the general run of the practice of medicine How much of this enormous field is occupied? From 16 to 20 per cent of the venereal diseases are reported by physicians,and perhaps not more than twice that percentage, 30 or 40 per cent, are treated by the profession Of the cases that are seen by physicians and treated by them, it is safe to say that even those cases do not receive or take one third of the treatment that is needed in the interest of both the individual and the public No one well informed as to the prevalence of this group of diseases can seriously consider the treatment given as compared with the amount of treatment needed without again agreeing that the unoccupied field in this sector is from two to five times greater than that which is adequately held by the forces of science

Again, we hasten on We have arrived at adult life In the interest of time, we introduce but one witness, but that an altogether sufficient one for the question involved The Life Extension Institute of New York, in the last two years, has examined about 250,000 people, of both sexes, all races, engaged in various industries and living in different parts of the country, the persons examined being selected indiscriminately with reference to appearance The institute found that about 60 per cent of those examined were in need, at the time of examination, of medical treatment, and not more than 20 per cent of those needing treatment were receiving it In short, it was found that, in adult pathology, the field was about one fifth occupied and four fifths unoccupied

Truly, the fields are white unto the harvest, but the laborers are few This great surplusage of disease makes the interest of the profession and the public one, binding citizen and physician in a common purpose coupling the determination of the public to remove disease surplusage with the ability of the profession to bring about the removal Let those shallow minds and timid souls among the brethren who fear or feign to fear a curtailment of professional opportunities and rewards both material and immaterial, remember that only through the use of medical science, only by making the field of medicine larger and more attractive can this waiting, unoccupied field of medicine be reclaimed from the domain of ignorance and need

DEVELOPMENT OF THE MUTUAL INTEREST

Medical science cannot hold the nose of the public and pour remedies down its throat, it is not a child incapable of thinking, insusceptible to advice and reason The need of remedies and the value of remedies must be explained to the patient, and a desire to be treated created in the patient's mind In short, a greater demand for the application of medical science to the existing surplusage of disease must be developed

INCREASING THE DEMAND

In increasing the demand for medical science, in intelligently enlarging the usefulness of medicine, we have an educational problem confronting us Intelligence appreciates, uses and pays for medical science, but ignorance neither appreciates, uses nor pays

There are two principal ways of developing this educational work One way is by the written word, bulletins pamphlets, press articles and literature in various forms The other way is by the living voice addressed to individuals collectively The first is the method of the Bible, the second, that of the preacher

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

The first way is the usual method pursued, and, in general terms, about the only method available for such central agencies as federal, state and associational health services, furthermore, for most local health agencies, in which personnel in proportion to the population to be reached is limited, education by the written word is the method that has to be depended on very largely The second way, the living word, is a method that exists potentially rather than actually It is needed for close-up work, it has the element of personal contact which carries, in addition to the letter, the spirit that gives it life, it is the only way that a large, unreading, potentially influential voting population gets its information and its inspiration The first way, by the written word, scattered broadcast through printed page from some long distance agency, is helpful and is necessary as is the barrage in preparation for a hand to hand fight, but the second way, by the meeting of the masses in person, talking to them collectively, answering their individual questions before collective groups, dealing with them as man to man, is as necessary to carry the strongholds of superstition and prejudice for the forces of science and progress as is the infantry attack in battle

It is not necessary to discuss here public health education through the written word We are all familiar with that I do, however, want you to consider carefully the need and the potentialities of educational work through the living voice, directed toward raising the popular intelligence with respect to the prevalence of disease and impairments and the more extensive use of medical science Consider, if you will, the weak position of our church or denominational organizations if these organizations depended on their state publications, their correspondence and their traveling evangelists, having no local and fixed group to do the collective educational work through the living voice, following this with pastoral or case work which the preaching makes possible and extends Our local physicians, members of county medical societies, make their pastoral calls to heal the body sick physically as the minister makes his local call to heal the body sick spiritually, but they do not complete the local minister's program, they do not speak to their congregations, they do not preach the gospel of good health, of right living here, they do not teach the people collectively

The county and local medical societies, particularly the rural medical societies, must become better organized for other purposes than merely to meet once a month, discuss differences of opinion with respect to scientific problems and occasionally construe the code of ethics They must become organized to meet their social, collective, larger and common opportunities and obligations to what Dr Osler used to refer to as the larger audience

Our units of medical organization are so constituted today as to inhibit rather than encourage the education of the local people collectively by the living voice of their own physicians Let some member of the average county medical society begin to make public addresses in his county on subjects in which he is especially interested and which are of far-reaching importance to the general welfare no matter how worthy his purpose and how well performed his task, he unavoidably takes an advantage of his fellow practitioners, in that he, in educating his own people collectively, inevitably advances himself personally, he is looked on askance by his fellows is called an advertiser is discouraged, and suspends operations Only the outsider from some distant point can speak to the people of the county without the risk of suspicion

Suppose, on the other hand, that the average rural county medical society, say with twenty-five members, selects twenty-five subjects which will include 90 or 95 per cent of the information on hygiene and health that the county people need, and secures the promise from each of its members to speak or read once each month an address or paper which the county society writes, or secures from some outside source and finally adopts as its own address Note that the address or paper is now not that of the person who presents it, but is that of his profession Such a program would mean a total of 300 public addresses during the year, which, given to average audiences of only 100 people, would reach a total audience during the year of 30,000, that is practically the entire population of the county Under such an arrangement, collective medicine would make contact with collective thought, and no outsider, federal official, state official or any one else could come between the local group of physicians and their own people It is high time that the organic units of the medical profession begin to assume their rightful leadership in public thought, the local professions no longer being content with pastoral visits and with no well considered plan of collective work for the physical salvation not only of their people but of themselves as well

SUPPLYING THE INCREASED DEMAND

As organization of the local unit of the profession, *that is, the county medical society* is necessary to increase the demand for medical science and enlarge the field of medicine, so, too, the organization of the county medical society for the purpose of supplying the increased demand will be necessary I shall touch only briefly on this phase of the subject

The primary demand will be for examinations and diagnosis The educational work above outlined will cause hundreds and thousands of those who become interested in the matter of health to wish to know whether they have an incipient or unrecognized disease or impairment, or whether, by alterations in living habits, their health may be promoted to a higher level A secondary demand that will arise in consequence of such physical examination will be a more extensive demand for treatment

In providing for these two demands, more adequate diagnosis and more adequate treatment through organized effort, it will be found that the plan of organization will involve both the local profession and the public, and will embrace both professional and business considerations—the former relating to the profession, the latter to the public The two organizations, profession and public, and the two main considerations, professional and business, will merge and find their proper relations in a public county clinic, run and manned by the profession, and financed by the community

In considering the professional organization of such a clinic in an average county of twenty-five practicing physicians, a service of four hours a week from each physician would provide 100 hours of professional service every week for the county Such a public clinic could operate two afternoons, for four hours each, every week, with twelve physicians in attendance, or four afternoons, for two hours each, with ten physicians in attendance, or four afternoons, for three hours each, with eight physicians in attendance However, the

number of hours served by the combined county medical society, and their arrangement of one day, or one afternoon, or several afternoons, and in groups of four, six, eight or ten physicians, are details for the consideration of the local county society With 100 hours a week, and with physicians working in groups as they did in examining the drafted men during the war, from 100 to 150 people a week, from 400 to 600 a month, from 5,000 to 7,000 a year could be examined

As a result of these examinations, a greatly increased demand for medical treatment will inevitably arise Those needing and seeking treatment may be classified into those who can pay and those who cannot pay The first class would be referred by the clinic to their family physician In considering the second class, those who cannot pay, the charity practice of the county, we come to the business considerations involved in this organized effort to meet the increased demand for medical science

In dealing with the business elements which enter into this problem, it will be well to observe, at the outset, that the burden of charity practice, constituting from 20 to 40 per cent of practice, should not rest on twenty-five citizens of the county, that is, on the twenty-five practicing physicians, but it is a burden which should be distributed and which should rest on the entire citizenship of the county, its 30,000 people All treatment administered in the clinic to the needy should be paid for by the public, and the funds paid in divided among the physicians serving the clinic, according to details to be worked out jointly by the county medical society and the group representing the public

In securing funds for such a clinic, the following possible sources are to be considered (1) a nominal charge against all who apply for clinic benefits, (2) local Red Cross chapter funds, (3) local funds received through the sale of Christmas seals, (4) appropriations by the city or town authorities, (5) appropriations by the county authorities, (6) an annual church collection from the churches of the county in response to the commission "heal the sick," and (7) contributions from benevolent and financially able citizens of the county With the educational work on which all this is predicated, the necessary revenue to maintain a public clinic would be assured

A business organization of interested, broad-visioned, public-spirited men and women should be effected, in order to organize the people of the county around the clinic Such a lay organization would assume two definite tasks (1) arranging for the places and notices for public addresses by the physicians, and (2) securing funds with which to finance the clinic

The local medical society would work out with this group of business men, and define on paper, the conditions under which the business group, representing the community, would issue cards of admission and requisitions for treatment to those who applied In the whole scheme, the local society, through organized effort, would assume the initiative, and approve everything that was done in providing for both the increased demand with respect to diagnosis and the increased demand for treatment

The profession at present is extensively and intensively interested in the development of public hospital facilities This is a worthy interest, and should be encouraged in every way But the hospital is something that will come only when the local county people have been informed through educational methods as to the prevalence and meaning of disease and impairment, and when they have demonstrated, through a public clinic, what can be done through organized effort in the treatment of disease and impairment In short, public organization to care for disease and impairment in an adequate way will follow and never precede professional organization We shall have organization and cooperation without when we get organization and cooperation within

ABSTRACT OF DISCUSSION

DR W S LEATHERS, University, Miss I have had the opportunity during the last several years of making observations along the line that Dr Rankin has discussed, and I believe that he touches a most important phase of preventive medicine when he emphasizes the unoccupied field of medical practice There can be no question about the fact that the surplusage in the treatment of disease is one of the outstanding phases of public health work in the prolongation of human life Reference is made to maternity and infant welfare work and the relation of the midwife to infant mortality In my own state, a careful survey has been made during the last year as to the number of midwives, and it appears that there are more than 4,000 in Mississippi, more than 95 per cent of whom are negroes It is doubtless true that about 40 per cent of all births are attended by midwives who are incompetent and uninformed It is clear, therefore, that this is a matter that should give us much concern in the conservation of the health of mothers and in the prevention of infant mortality In view of the fact that the physicians in many of the states are not well distributed in relation to the population there is at this time a considerable restlessness on the part of the general public relative to the care given them from the standpoint of the medical profession The country people are not getting the attention which they think they deserve in the treatment of disease, and therefore there is a grave responsibility on the medical profession in the working out of a better adjustment or plan in giving medical attention and care to people in rural districts It seems to me that the time is rapidly coming when there should be in every county, or group of counties a hospital which shall be available for the people requiring medical attention, and which will afford them the very best medical aid It is quite discouraging to the family living in the country, say 10 or 15 miles, who needs medical attention and has to pay the physician $3 for the first mile and $1 for each mile thereafter This situation almost makes it prohibitive for the average family to secure the necessary medical attention Dr Rankin makes it very clear that education is fundamental in the prevention of disease and in the prolongation of life If the general public were educated properly the 50 or 60 per cent who have no appreciation of scientific medicine would seek the advice of a competent physician It is very desirable, therefore that public health activities should be so directed that the people are educated not only in the science of preventive medicine, but also relative to the importance of seeking medical advice promptly when ill The prevention and cure of disease are in a way inseparably associated for the reason that in many diseases an early diagnosis means prevention as well as cure.

DR A S HERSHFIELD, Chicago We are hard put as physicians to live down the errors of omission and commission of our forefathers There was always something mysterious about medicine, and even a patient who received a prescription written in Latin regarded it as something mysterious without ever taking the medicine There was something mysterious about the doctor, in other words, he appealed more to the mysticism of the public than to their intelligence He is trying to live it down now But, in this living down and treating the public as intelligent beings we find the Christian scientists and other sects coming in with the mysteries that we are beginning to abandon, and that is why they are enjoying the vogue they are today, because we are appealing to the intelligence and they are appealing to the mysterious That is something we have to preach Dr Rankin

enumerated a number of contributions to public health work, but I did not hear how he was going about preaching the danger of medical politics That is the essential factor The chiropractors and the other cults are thriving because they get in under the law The doctors sit back and let these people appeal to the mysterious that we are trying to live down We have nothing to back us politically Why can we not be politicians? If we are right in the work we are doing for public health, why can we not have men to represent us in the legislature and not politicians who laugh at us because we have no political standing and no physician wants to get up and fight for his right, because politics is below his dignity? He is sat on, he is taken advantage of, and the things we are trying to abandon are forced on us

DR A N MCCORMACK, Louisville, Ky Having for several days listened to the vapid utterances of some of the superficial and ignorant members of our own profession who had no more conception of its possibilities than they had of the simplicity of the wonderful method of salvation, it is refreshing to listen to the words of a wise man who would lead us out of the wilderness in which some of our noisy but utterly mistaken leaders are trying to bury us There is no trouble about physicians practicing medicine in the country districts, or about physicians in our cities who are carrying on the work, the trouble is from the various commercial organizations forming in the profession We are told that America needs more organizations for physicians and that the physicians of America are interested in nothing but their own livelihood The time is coming when those who work must rise and talk and must furnish our profession with leadership if we are going to get anywhere We have stayed too long silent, or these things could not happen Dr Rankin's paper will be mimeographed and sent to every physician in Kentucky, so that it will be read in every county society Down in Panama I saw this plan in operation, and I realized that there the public is so well educated that it demands real medical service, and it takes five times as many physicians as we have in the most thickly populated section of the United States to give that service, and it is to supply that demand that we must look forward to the real future in medicine, yet we hear our little folks get up and say, "There are enough doctors There is not enough foresight in this country yet to realize the number of physicians needed when Americans are made the healthy persons they ought to be with the knowledge we have as to how to keep people well

DR RACHELLE YARROS, Chicago I want to endorse practically everything that Dr McCormack has said We cannot have too many endorsements of such good sense, courage and progressivism There are many in the profession who share his views, but refrain from expressing them If such a paper will be read not only by the physicians of Kentucky, but by all physicians in the United States, many of the doubts and fears now entertained will disappear, creating a greater tolerance on the part of the profession toward some of the newer problems of public health Many of the difficulties that we encounter in this connection are no doubt due to the fact that most members of the profession have far too little time to follow the new developments in medical work of today and the modern demands that society is making on us We must learn this lesson as quickly as possible that health education of the lay public is always helpful to the profession It always creates greater demands for the services of physicians as well as gives greater opportunity for work in new fields This can be illustrated most clearly by citing the instance of the education of the public in venereal disease control work The same no doubt can be said about tuberculosis and other public health measures such as the bill for better maternity care" as Dr Rankin stated so well My experience is that the public is now more ready than ever to receive and benefit by health education, and naturally looks to the profession to take the leadership in supplying such education Unfortunately, too many physicians have adopted a short-sighted attitude and have either stood aside or actually fought every progressive tendency in public health, making every effort to minimize the value of education of the lay public in health matters It is a pity that physicians in fighting the newer measures of public health have produced the impression among enlightened laymen and social workers that they are actuated solely by selfish considerations As a profession, we must begin to abandon our extreme individualistic attitude and train ourselves to cooperate more readily with social agencies working toward the physical and mental health of the public Public health and hygiene are not purely medical problems They have economic, sociological and psychologic aspects which we must recognize We must be willing to exchange ideas with workers along those lines When we cannot lead, we should be willing and glad to work with others on a footing of equality

DR DUNCAN B MCEACHERN, Chicago Dr Rankin simply makes a plea for what might be called historical perspective. If medical men would take a historical perspective of society, it would be quite evident that society is an evolutionary affair We can go back before the establishment of public schools, when the education of the people was detailed to individual teachers, and we can see how unsatisfactory that method of teaching would be if applied today The medical men of today are in the same position that the schoolteachers were before the days of Horace Mann They are trying to apply their knowledge individually instead of *en masse* I do not care whether you call it state medicine or not, but the activity of the medical man must be along the lines indicated by Dr Rankin The medical man has to accept the responsibility for this 60 per cent untreated disease that exists in the community The amount of disease in a community is a measure of the efficiency of the medical profession Eventually state or public health organizations will have to take over the activity of the medical man He has been in the habit of looking at the general public as something to exploit A wise physician once said to me that all professions were conspiracies against the public, that the average man is out to get something from the public instead of giving something to the public The public demands the same measure of intelligence in handling its health problems as it does in handling its educational problems Unless the medical man will look at the matter in this light, the public will take affairs into its own hands In the schools we might establish small clinics, and there should be several beds in schools for children who need tonsillectomies I think that every school should be furnished with an optical department, and glasses should be furnished the same as textbooks are

DR W S RANKIN, Raleigh, N C I want to say a few words regarding the activity or inactivity of the health officers in dealing with sectarian medicine Let us see who is responsible for it The state representatives come to the state capitol and pass laws Those laws reflect the feeling of the people back home They pass laws regarding sectarian medicine because the people back home have not been educated against the evils of quackery If physicians were organized and were in touch with collective thought, there would be no man in the state legislature voting for chiropractic and other sects It must come back to the collective work of the men in the ranks In an organized county in North Carolina, lectures are to be given to the people once a month dealing, among other things, with sectarian practice, chiropractic, osteopathy and all the other false doctrines that have preceded them, and there will be no legislative sentiment in support of them The general practitioners are the soldiers in the ranks, and if they do not become active, we shall never establish this public health work When you come to think about it, there is only one really live adult organization, and that is the church Churches are well organized What do they do with a new member? They try to get him to do something It does not make any difference whether it is teaching Sunday School or what it is, but they want him to work If he is not made active, he is not interested If the church does not get him interested, what happens? The man does not go to church except when his conscience bothers him He does not know what the church is doing He misunderstands, he criticizes he obstructs and hinders If we can get the physicians of this country actively interested in public health work, both the profession and the public will be benefited

DRUG THERAPY IN PYELITIS*

HENRY F HELMHOLZ, M D
ROCHESTER, MINN

The present study is concerned with an attempt to determine the direct mode of action of several of the more commonly used drugs in the treatment of pyelitis The action of the alkalis, of hexamethylenamin and of phenyl salicylate has been studied

First it must be said that pyelitis, in most instances, is a self limited disease, which may disappear almost as rapidly as it appears It is sometimes discovered accidentally by routine examination of the urine At other times, it may be associated with very severe symptoms, being, even, rapidly fatal, owing to renal complications Our inability to distinguish between pyelitis with and without renal involvement makes it extremely difficult to differentiate, at the onset, the severe from the mild, at present, the clinical course is the sole criterion This difficulty practically rules out the possibility of comparing the various modes of treatment by studying a given number of cases In treating the same patient first in one way and then in the other, it is impossible to determine whether the disease would not have cleared up if the first treatment had been continued instead of the second being instituted

In taking up the value of alkalization from the historical standpoint, Thompson of Edinburgh seems to have first emphasized the value of alkalization of the urine on purely empiric grounds He has given no theory of action, nor has any one given us a satisfactory explanation of its value In a recent article on the treatment of pyelitis, Browning[1] says, "The change in reaction of the urine causes the tissues to be bathed in a fluid which is more bland, and thereby enables them to combat the infection more effectually" Normal urine is slightly acid, so that the normal mucous membrane of the urinary tract is developed to withstand these degrees of acidity without damage Whether this applies also to an inflamed mucous membrane has not been determined

The question that naturally arises is whether the alkalization is merely a means of increasing urinary output and flushing the passages, or whether it has a definite specific effect The greatest alkalinity that has been found in urine of human beings is p_H 8 6, the same as a saturated solution of sodium bicarbonate Since in this alkalinity the colon bacillus grows luxuriantly, it is evident that this degree of alkalinity is insufficient to influence the clinical condition by its action on the growth of this organism The growth of the colon bacillus is not inhibited until the hydrogen ion concentration reaches from 9 2 to 9 6 Since, at the acid end, inhibition of growth occurs at from p_H 4 6 to 5, and urines with hydrogen ion concentration as high as 5 may occur, the inhibitory action by acidity alone would be possible

After the disappearance of the general symptoms, fever, malaise, anorexia, and so forth the urinary findings in pyelitis are usually as marked as before, so that it seems possible that the alkalinity might prevent the formation and absorption of toxic products producing the general symptoms Experiments were conducted in order to determine whether there is a difference in toxicity when the colon bacillus is grown in acid broth and when in alkaline broth Bacilli were grown at an acidity p_H 5 4 and at an alkalinity of p_H 8 6 for twenty-four hours, the cultures were then filtered, and the filtrate was injected intravenously into rabbits, similar amounts of the acid and of the alkaline broth being used as control The reactions were practically identical Both the alkaline and the acid broth produced a febrile reaction of from 2 to 5 degrees, the filtrates caused a slight rise of temperature and then a marked lowering of temperature The reactions of alkaline and acid filtrates were practically identical The difficulty of growing the organisms at a definite hydrogen ion concentration is that ordinary alkaline mediums in which there is sugar rapidly become acid, and acid mediums more acid Sugar-free alkaline mediums become more alkaline and sugar-free acid mediums tend to become alkaline In these experiments, an excess of sodium bicarbonate was added to the alkaline broth and a buffer mixture to the acid broth, so that the hydrogen ion concentration after twenty-four hours was within two tenths of that before inoculation

A number of observers have said that if alkalization does not clear up the infection, the rapid change to the use of hexamethylenamin and acidification proves effective This treatment may owe its effectiveness entirely to the action of the hexamethylenamin, on the other hand there is a possibility that the beneficial effect is due to the lag observed in the growth of bacteria when their culture medium is changed The lag is the time required for the bacteria to acclimate themselves to their new surroundings The change from acid to alkali, and vice versa, might tend to retard the development of the colon bacillus We, therefore, studied the rapidity of multiplication of the colon bacillus when grown in acid broth and transplanted to alkaline, as compared with that of one that was grown in alkaline broth for numerous generations, and vice versa No striking differences were observed in this series of experiments when they were carried on in mediums without a buffer As the growth of the colon bacillus changed the hydrogen ion concentration of the medium very rapidly (so that if the concentration at the time of inoculation is 8 6, after a few hours of growth it may be only 6 4), it was thought best to repeat the experiments in mediums with buffer mixtures, so that the reaction, after twenty-four hours' growth, would be very nearly the same as before inoculation It was not possible in any of the experiments to demonstrate any appreciable lag when the colon bacillus was transferred from an acid to an alkaline medium, and only a very slight lag when it was transferred from an alkaline to an acid These experiments do not exclude any effect that the alkaline mode of treatment may have on the formation of bactericidal substances by the mucous membrane

A special effort has been made to determine whether there was any action of hexamethylenamin at the level of the pelvis It is well known that urine from the bladder, if acid, can be rendered sterile by hexamethylenamin According to the experiment of Shohl and Deming,[2] with a hydrogen ion concentration of 5 2 and a total urinary output of 1,500 c c, a dosage of 3 gm of hexamethylenamin will produce formaldehyd in two hours sufficient to kill 90 per cent of all bacteria

---

* From the Section on Pediatrics Mayo Clinic

* Read before the Section on Diseases of Children at the Seventy-Third Annual Session of the American Medical Association St. Louis May 1922

1 Browning C H The Diagnosis and Treatment of Nonvenereal Pyogenic Infections of the Urinary Tract with Special Reference to Urinary Antiseptics Glasgow M J 97 38-45 (Jan) 1922

2 Shohl A. T and Deming C L Hexamethylenamin Its Quantitative Factors in Therapy J Urology 4 419 (Oct) 1920

They have also shown that the nearer the reaction of the urine approached neutrality, the lower was the concentration of formaldehyd and antibactericidal action With a p_H 6, insufficient formaldehyd was formed even in twenty-four hours to kill all bacteria At neutrality, there was no production of formaldehyd In infants, the urine rarely remains in the bladder more than from one to one and one-half hours Even if conditions of acidity in the urine of the bladder are ideal and the hexamethylenamin is sufficient, it would be almost impossible to obtain a bactericidal concentration of formaldehyd because of the lack of time

I recently observed a child who had suffered from pyelitis for three years Ureteral catheterization, some months before, showed bilateral infection of the renal pelvis The urine, on first examination, contained innumerable bacilli, but only a few pus cells The child was put to bed, fluid was forced, and 15 grains of hexamethylenamin and 20 grains of sodium acid phosphate were given every six hours In spite of the sodium acid phosphate, the hydrogen ion concentration of the urine remained about 7, varying from 6 8 to 7 4 At the end of eight days, the urine of the bladder was sterile, but numerous bacteria could be seen in the centrifuged specimen A few days later, the child underwent cystoscopy, and urine was obtained from both ureters and from the bladder, and cultures were taken All the cultures were sterile, and the hydrogen ion concentration was 7 4 What had caused the disappearance of the infection? The urine was alkaline, the formaldehyd could never be in sufficient concentration to be bactericidal There is, of course, a possibility that disappearance of infection was merely a coincidence, or due to rest in bed and forcing of fluids, but the three year history is rather against such an assumption It raises the question of a possible action of hexamethylenamin in alkaline mediums A particularly interesting experiment was made to determine the condition of the urine from the ureters, when the urine from the bladder contained sufficient formaldehyd to sterilize it, and to determine the length of time required to render the urine from the ureters sterile Thus far fourteen cases have been studied, but an appropriate, deciding case has not been found

Experiments with the use of phenyl salicylate (salol) have been somewhat limited, because indications did not warrant further investigation They consisted of two cases of pyelitis in which the dose of phenyl salicylate was increased gradually to a point at which it was unjustifiable to go farther

In the case of one patient suffering from pyelitis, the dose of phenyl salicylate was increased to 5 gm daily, without any effect on the bacteria in the urine With this dose, the urine was not bactericidal, and it turned rapidly dark on standing, indicating the presence of pyrocatechin and hydrochinon In the case of another patient, the dose was increased gradually to 4 gm daily, at which time there was rapid change of the color of the urine, to a dark brown In neither instance was any antiseptic action observed Since these doses are much higher than those usually advised for the treatment of pyelitis, I feel warranted in maintaining that, in the doses usually given, phenyl salicylate has practically no value in rendering the urine sterile by its direct action on bacterial growth

From a review of the literature of pyelitis, particularly of its treatment in infancy, the impression is gained that few observers have found hexamethylenamin of much value In most articles on the subject, alkalization is the treatment of choice in the acute cases However, there is no evidence that alkalization has any direct specific effect, except, possibly, its diuretic action The possible effect of alkalization on the tissues is not considered in this paper, it being the subject of a separate experimental study

SUMMARY

In acute cases of pyelitis, the alkalis are useful, but we have no evidence of any direct specific action Hexamethylenamin has a very definite bactericidal action in the bladder, but whether this applies also to the pelvis of the kidney has not been demonstrated Phenyl salicylate does not have antiseptic properties in the doses given

UROLOGIC SURGERY IN PEDIATRICS*

HERMAN L KRETSCHMER, M D

Genito Urinary Surgeon Alexian Brothers Hospital Urologist Presbyterian Hospital Consultant in Urology U S Veterans Hospital No 76 Assistant Surgeon Children's Memorial Hospital

CHICAGO

It may be said without fear of contradiction that the urologic study of pediatric cases has not received the consideration that is due so important a subject This is practically an undeveloped province of medicine, and as evidence of this statement, attention may be called to the scant references, both in pediatric and in genito urinary literature In this country, Beer,[1] Hyman,[2] Hinman,[3] Stevens,[4] Thomas and Tanner,[5] and Helmholz and I[6] have made a study of the subject—not a large showing Hence, it appears to me that this province for clinical study has been decidedly neglected, though the problems and possibilities undoubtedly are many and of great variety But to achieve gratifying results, the closest cooperation between the pediatrician, general practitioner and genito-urinary surgeon is necessary This alliance effected, I am ready to admit, without being unduly enthusiastic, that pediatric urology will be the open sesame for extensive work for both pediatricians and urologists

On reflection, it appears that there is no really sound reason for this backwardness of pediatric urology A perusal of the table of diagnoses (Table 2) shows that the lesions of the genito-urinary tract in children differ in no way from the various pathologic conditions found in adults, except as regards those incident to age, such as carcinoma Then what are the reasons for this failure to keep abreast of the advances made in urology in adults? The reasons are

1 The general practitioners and pediatricians who attend infants and children have not availed themselves of the advantages and opportunities of urologic studies because of the difficulty in eliciting symptoms in these patients, and probably because they are not familiar with the possibilities inherent in this subject

2 The genito-urinary surgeon is not the first one called to see these cases, and, furthermore, there are certain limitations in his armamentarium With the recent advances in the art and science of instrument making, instruments of small caliber have been perfected, so that these little patients can be subjected to cystoscopic examination and ureteral catheterization almost as easily as can the adult Not only can these patients be examined with special instruments of precision, but the same diagnostic measures that are employed in the adult can be and should be used, namely, roentgen ray, pyelography, functional tests, blood chemistry, and chemical and bacteriologic studies of the urine as obtained by ureteral catheterization

This article is based on a personal experience in a series of sixty cases

INDICATIONS

The indications for urologic study in children are the same as for adults, but their verification is difficult, since many children cannot accurately describe their symptoms Especially is this evident in the treatment of infants, for one must rely on the statements of the parents or nurse, whose powers of observation are often not very keen, or, in fact, so defective that frequently the chief indication must be based on the results of urinalysis

The presence of pus in the urine (thirty cases) was the most frequent single indication for cystoscopy in the group herewith reported A large number of the

Fig 1—Hydronephrosis and enormous dilatation of ureter catheter forming a loop in the ureter

patients came to the hospital without any very definite complaints In the course of the routine physical examination, pus was found in the urine and for this reason the patients were referred for study

Hematuria as an indication for complete urologic study is very common in adults and quite the reverse in children This is due to the common occurrence of tumors in adults and their rarity in children The presence of macroscopic blood was the reason for cystoscopy in only eighteen cases

In several cases, the patients were examined with the cystoscope because of enuresis, and, while this may not

Fig 2—Large solitary pure cystin stone

always constitute an indication for cystoscopy, it is well to employ the cystoscope in these cases, in order to exclude a possible pathologic condition in the bladder that might be responsible for the enuresis In one case, that of a boy, the cystoscope was employed because of an overdistended bladder, the bladder extending above the umbilicus The patient, who was admitted to the

hospital because of overflow incontinence, suffered from a congenital valve formation at the neck of the bladder Two boys were referred because of bed-wetting Cystoscopic examination revealed the presence of stones in the bladder

LIMITATIONS OF CYSTOSCOPY

In boys, for anatomic reasons, cystoscopy and ureteral catheterization cannot be carried out as early as in girls The youngest patient in this series was a girl, aged 7 months at the time of the first examination In this patient, ureteral catheterization and pelvic lavage were carried out As previously mentioned, very small instruments are now available for both cystoscopy and ureteral catheterization

SEX AND AGE

In this series of 60 patients, twenty were boys and forty girls

The youngest child in whom ureteral catheterization was done was a girl, aged 7 months, the youngest boy in whom a plain cystoscopic examination was made was 11 months old The ages are indicated in Table 1

DIAGNOSIS AND SYMPTOMS

In Table 2, the fact is made clear that the various lesions met with in infants and children are not very

different from the lesions which occur in the ordinary run of adult urologic cases, with the exception of lesions incident to age, such as malignant tumors of the bladder and prostate and hypertrophy of the prostate In adults, the common malignant kidney tumor is

Fig 3—Three small cystin stones in the bladder

hypernephroma, this tumor rarely, if ever, occurs in childhood On the other hand, sarcoma of the kidney is more frequently seen in children than in adults

The symptoms, analyzed in Table 3, are similar to those which occur in adult cases, taken at random Hematuria, a relatively common symptom in adults, is rather uncommon in children, nevertheless, the presence of blood in the urine either grossly or microscopically was recorded in eighteen cases

PYELOGRAPHY

In the series of cases described, pyelograms were not made in every instance, my attitude in the matter being conservative, that is, only when indicated was this procedure followed While accidents and complications following pyelography are few and far between, it cannot be denied that adults suffer at times rather severe reactions Bearing this in mind, and also the

Fig 4—Extensive calcification in the right kidney in case of bilateral renal tuberculosis

fact that many of the children had been examined cystoscopically under anesthesia, and considering the difficulty of determining just when the pelvis is completely filled, I have been rather reluctant to subject

them to pyelography, unless it was absolutely necessary But it should be emphasized here that pyelography yielded valuable information in a number of instances In a girl, aged 9 months, in whom a provisional diagnosis of chronic colon pyelitis had been made and pelvic lavage instituted, it was soon evident, because of the failure of the patient to respond to this treatment, that something besides a simple pyelitis was present This was substantiated by the pyelogram, which revealed a hydro-ureter and hydronephrosis In another case, the pyelogram revealed a stricture of the ureter, with enormous dilatation of the ureter and kidney pelvis,

the ureter being large enough to allow the catheter to bend, forming a large loop (Fig 1)

It would appear, judging by what has just been stated, that, even in very young patients, pyelography has a definite field of usefulness in selected cases

CYSTOGRAPHY

While cystography has a rather limited field in the urologic study of adults, its field of usefulness is probably still more restricted in pediatrics, and it should be supplemental to, and not substituted for, other procedures The making of cystograms in cases of children has been previously reported [7]

ROENTGEN RAYS

Roentgen-ray examinations should be carried out in all cases, with the realization, however, that there are certain cases of calculus that cannot be demonstrated by roentgen rays One patient, a boy, aged 2, had a large vesical calculus which was not demonstrated by the roentgen ray but was diagnosed by cystoscopy In three cases, the roentgen ray revealed the presence of calculi (Figs 2 and 3), and, in two cases of renal tuberculosis, the presence of extensive areas of calcification (Fig 4)

URETERAL REGURGITATION

Regurgitation of the fluid up the ureter was noted under two different circumstances (1) in normal children with normal urinary organs, free from infection, in whom the bladder was filled with solution for purposes of cystography, and (2) during ureteral catheterization This phenomenon was proved by injecting a

Fig 5 —Bilateral pyelogram in a girl aged 7 months showing enlargement of the renal pelvis

solution of argyrol into the bladder Shortly afterward, the urine, dropping from the ureteral catheter, was colored with argyrol solution Both these occurrences have previously been reported the latter in an article on the treatment of pyelitis in children

BACTERIOLOGY

Bacteriologic records were positive only in thirty-six of the sixty cases Although the number of cases in which bacteria were found is small, it is not without interest that, according to Table 4, the organism which preponderated was the colon bacillus Various writers

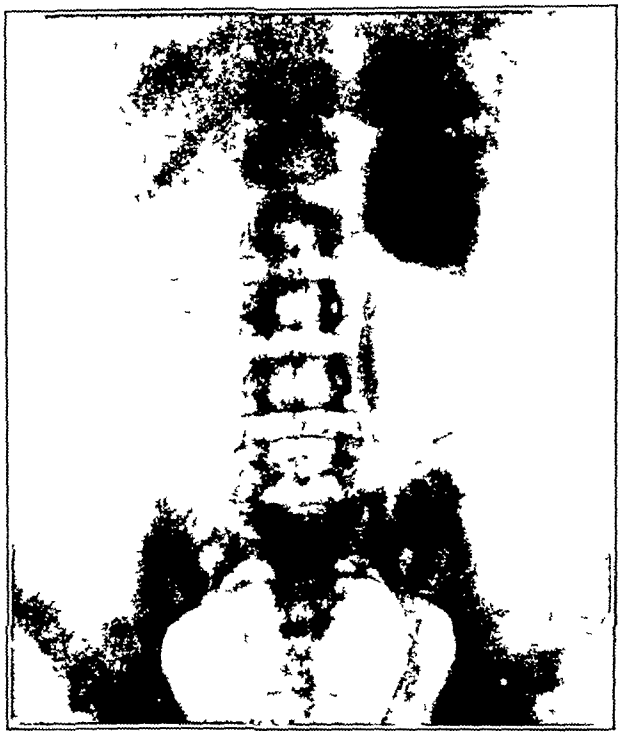

Fig 6 —Hydronephrosis in a girl aged 13

have stated that the colon bacillus is the most frequent invader of the urinary tract in adults My experience in this series of pediatric cases corroborates this opinion

LITHOLAPAXY

Another urologic phase of pediatrics that has received little, if any, consideration in this country is the treatment of stone in the bladder In India and in

TABLE 4—RECORD OF ORGANISMS FOUND

	Number of Cases

certain parts of Russia, litholapaxy has been resorted to in the treatment of bladder calculus in children Frever, in England, has reported a series of 140 litholapaxies in children

In two cases in this series, litholapaxy was successfully carried out (Fig 2) Rather large stones were crushed and completely removed, as evidenced by subsequent cystoscopic examinations Chemical examinations of the fragments of both these cases showed the presence of pure cystin [8]

PELVIC LAVAGE IN PYELITIS

A certain number of cases of colon bacillus pyelitis resist all the usual forms of routine treatment, such as administration of alkalis or hexamethylenamin or the use of vaccines, or special diet This group forms a very small number, to be sure, yet the problem of management in cases of relapsing pyelitis which do not respond to treatment is an important one, and one that has not received intensive study

In a paper presented before the urologic section, Dr Helmholz and I[6] reported a small series of cases in which pelvic lavage was carried out with satisfactory results Further experience with pelvic lavage, in cases of pyelitis which have resisted all other forms of treatment, has yielded results that justify this form of treatment when the usual forms of treatment fail to cure these small patients

SUMMARY

1 From a careful study of this series of cases, it is evident that the various pathologic conditions in infancy and childhood are similar to the various urologic lesions found in adults

2 The diagnostic and therapeutic problems are identical

3 There is no sound reason why these little patients should not be given the benefit of modern urologic diagnosis and treatment

4 With a more widespread interest in this subject, more patients will be given the benefit of urologic diagnosis and study

5 No doubt, with the study and the report of increasing series of cases, the entire subject will become more and more stabilized

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS HELMHOLZ AND KRETSCHMER

DR CLIFFORD G GRULEE, Chicago One might get the impression, if he had not listened closely, that there was no benefit to be derived from the administration of alkalis I take it that Dr Helmholz did not have that in view The results of alkali administration in pyelitis, if carried out faithfully, are not to be questioned, and as a consequence I think, if I am not much mistaken, that Dr Helmholz meant to say that his experiments had not yet shown how the alkalis acted Evidently they had no marked bactericidal effect on the colon bacillus As to Dr Kretschmer's paper, I think it represents a general tendency Our tendency in medicine has been to attempt to get something definite on which we can place a finger and say that this means something here and now That is the reason the laboratory findings have been so exaggerated in importance by many because they felt that laboratory tests were something exact and something on which one could depend As a matter of fact, any one who has done any amount of laboratory work knows that laboratory tests are subject to individual interpretation, and therefore they are of no more importance from the standpoint of diagnosis than anything else which is subject to human error In this work we have demonstrated another approach in exact diagnosis, an approach which has not been used to any great extent and one which I feel will be of great value if we are careful in the selection of our cases It is very satisfactory to have a cystoscopic examination or a catheterization of the ureters and to feel that you have reached the bottom of things in that respect Another phase of this work which is not to be disregarded is the question of the treatment of pyelitis Every one has seen cases of pyelitis in which the pus has persisted in the urine in spite of every effort on the part of the physician to overcome the pyelitis Dr Kretschmer does not claim that every case of pyelitis which he treats by his method and which is essentially a neglected case of pyelitis is going to be cured by such treatment But when a case reaches the point at which approach by that method of treatment is impossible, this washing out of the pelvis of the kidney with silver nitrate solution is of the greatest benefit and in some cases has resulted, if not in cure, in betterment of the condition Pyelitis has such a marked tendency to recurrence that cure must be spoken of advisedly But, on the other hand the clearing up of the pus in these cases is one of the things which we are glad to obtain

DR CHARLES SCHOTT, Chicago I think many pediatricians have regarded this work as an adjunct which might help us to come to a conclusion in a case which is more or less puzzling Many men would like to employ this method of diagnosis, but cannot call on somebody to help them out It seems to me that it takes a real expert to do this work A crude operator may do more harm than good so that the ultimate value of the thing might be nullified In hospital work, every method should be used to arrive at a diagnosis, so that at some future time we may say that here in this case cystoscopy is not necessary because we have used it in so many cases experimentally, perhaps

DR W MCKIM MARRIOTT, St Louis Two remedial agents have not been mentioned—calories and cod liver oil There is a type of pyelitis that is secondary to malnutrition and will not be affected by any form of drug therapy unless the nutrition of the child is improved In such cases, if the infant is treated the pyelitis will clear up of itself Dr Helmholz has pointed out many ways in which the commonly used drugs do not work Most of us, however, feel convinced that alkalis are of distinct benefit There are one or two good reasons why one should expect alkalis to effect a favorable influence on pyelitis We know that phagocytic immunity is inhibited in acid solution We know that phagocytosis is one of the defenses of the body in pyelitis We would not expect phagocytosis to be active in the presence of an acid urine, hence the advantage in neutralization of the urine Furthermore, we know that it is not the pus in the urine that is doing harm, but the pus retained in the kidney that causes the symptoms One frequently sees patients with high temperatures with no pus in the urine When the pus appears, the temperature falls We know that pus is more soluble in alkaline than in an acid medium Is it not possible that alkalization of the urine aids in dislodging retained pus? Potassium citrate is a drug frequently used, although there is no good reason for the use of potassium salts Sodium salts are quite as effective, and are free from the danger of potassium Potassium salts are toxic, but they are rapidly eliminated in the urine under normal conditions, in pyelitis, however, retention may occur and definite symptoms of potassium poisoning result Only the sodium salts should be used when it is desired to administer alkali

DR F C RODDA, Minneapolis We know little about the etiology of pyelitis, very little about the pathology, and less about the treatment Dr Helmholz' attempt to put the treatment on a scientific basis is to be commended The diagnosis of pyelitis is often based on finding pus in the urine and yet Dr Marriott has called attention to the fact that there may be bacterial invasion of the urinary tract with no pus On the other hand, after the disappearance of the constitutional symptoms, pus may continue for a long time We must have some criteria to tell when a patient is cured The presence or absence of organisms and the time when these disappear, is more important than the finding of pus As regards the alkaline treatment, it is often hard to say whether we are getting any result from the drug or not Often sodium citrate must be given up to 150 or 200 grains a day to get the urine alkaline, and yet we see physicians administering 5 or 10 grains twice a day There seems to be a fear of administering hexamethylenamin in reasonable doses We have given it up to 45 or 50 grains a day for a short time, carefully controlling the urine, of course, and watching for any signs of irritation

DR LOUIS C SCHROEDER, New York I do not believe that any man can do this urologic work I have seen barium used in a child with dilated ureters, the result of a congenital deformity, and the outcome was anything but satisfactory We know that in adults, some fatal results have attended the use of different substances employed in urography There is a distinct danger attached to it, and the impression should not go out that one can use any medium at all I am interested to know what medium Dr Kretschmer has used, for some mediums are toxic and should be avoided

DR FRANK C NEFF, Kansas City, Mo I would like to suggest that the use of phenyl salicylate might have some effect in the type of pyelitis due to pyocyaneus infections I saw such a case that was definitely cured by phenyl salicylate when the usual remedies failed A possible cause of persistent pyuria is a diverticulum of the bladder or a congenital anomaly in the posterior urethra which interferes with complete drainage of an already infected urinary tract Urologic examination will reveal such a condition and therefore should be resorted to much more frequently than pediatricians have been accustomed to doing

DR JAMES A GARDNER Buffalo Urology is one of the newer departures in medicine, and it is still difficult to persuade physicians to send adults to the urologists and even more difficult to persuade them to send children The impression prevails that instruments are made solely for use on adults In recent years the instrument makers have perfected the cystoscope so that we now have instruments that can be used with equal facility on children With the advances made in urology it has been demonstrated that children suffer from the same conditions as adults—diverticula, hydronephroses and pyelitis—and if an early diagnosis is made, infections, while they are still slight, are as easily cared for as in adult cases The doctor spoke of deaths occurring from making pyelograms I feel that there is really a small risk With sodium bromid solution we have reduced it to a minimum, and because of the large number of children who can be saved if a diagnosis is made, we are warranted in taking the risk

DR H F HELMHOLZ, Rochester, Minn Blocking of the ureters by acute inflammation is another condition that might be cured by the passage of a ureteral catheter We must keep this mode of treatment in mind because the acute case with obstruction is the one in which the patient is likely to die of the infection, and a certain number of these patients can be saved by restoring the passage in the ureter I purposely stated in my paper that I was discussing only the direct effect of drugs on bacteria and not on the organism The most important drug in the treatment of pyelitis which has not so far been mentioned is water All other drugs are merely an addition to water In a recent discussion in Washington Dr Hugh H Young, in whose laboratory a great deal of work has been done on drug therapy in kidney lesions, emphasized over and over again that water in large amounts is the most efficient drug in the clearing up of infections of the urinary tract, and I heartily agree with him

DR HERMAN L KRETSCHMER, Chicago It was not my object to emphasize any one phase of this subject but to present the experiences in this series of sixty urologic cases in infants and children, calling particular attention to the various diagnostic problems which are essentially the same as in adults problems that should be settled before treatment is instituted Much of the discussion has centered around the treatment of pyelitis by pelvic lavage I did not want to present this as a specific but the fact remains that in some of these cases we were able to effect a cure when all other forms of therapy had failed Pelvic lavage will not cure all cases and, when it fails, the question of a mistaken diagnosis immediately comes up Dr Helmholz undoubtedly will remember one of his cases in which pelvic lavage failed to cure the patient Further study demonstrated the presence of a hydronephrosis, so that when pelvic lavage fails to bring about the desired result, one should search for the presence of other lesions that might keep up a pyelitis, such as an early renal tuberculosis, stone or hydronephrosis The presence of some of these lesions, perhaps often unrecognized, may account for the failure of medical treatment I agree, most fully, with Dr Schott's statement about the necessity of making correct diagnoses in these cases—a point also emphasized by Dr Grulee I agree also with Dr Helmholz, namely, that we do not give large enough doses of alkalis and hexamethylenamin in treating cases of pyelitis Dr Marriott is perfectly correct when he says that we should treat the patient as a whole, a fact that I have repeatedly advocated in treating pyelitis in adults The point brought out by Dr Schroeder regarding deaths after pyelography is a very important one, and I stated in my paper that we did not make pyelograms in every case, reserving its use to well selected cases I do not believe that it makes much difference what medium is used We have used both sodium bromid and thorium The reaction, I think, is due to overdistending the infected kidney pelvis and carrying the infection into the substance of the kidney I do not believe that the reaction is due to the chemical although some chemicals undoubtedly are more irritating than others Dr Neff's point about careful urologic study is well taken, and I agree fully with him

---

SYPHILIS OF THE LUNG*

ALFRED FRIEDLANDER, M D
AND
R J ERICKSON, M D
CINCINNATI

The voluminous literature on syphilis of the lung is characterized by contradictions There is no unanimity of opinion as to frequency, type, anatomic picture or course The essential features of diagnosis are variously given It may thus well be that many cases of pulmonary syphilis are overlooked—that many cases of so-called lung syphilis are improperly diagnosed

The development of a finer roentgen-ray technic has made it necessary to revise our preconceived notions of pulmonary syphilis Indeed, there are not wanting roentgenologists of repute who feel that the roentgenologic chapter of lung syphilis is yet to be written

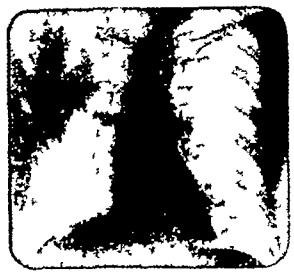
But in summing up the mass of evidence as presented in the literature, certain outstanding conclusions seem to be justifiable

Speaking in terms of visceral syphilis, the lungs must be regarded as organs which are relatively resistant In saying this, it is to be remembered that reference is had here to the lesions of acquired syphilis The "white pneumonia" of congenital syphilis described long ago by Virchow, Widal and others is excluded from the discussion Lung syphilis, as compared with other tertiary manifestations of the disease, is a comparatively rare disease According to Osler,[1] in 2,800 necropsies at the Johns Hopkins Hospital there were twelve cases of syphilis of the lung, and eight of these were of the congenital type—an incidence of the acquired type of 0 14 per cent In 1,200 cases referred to the Jefferson Chest Hospital, Funk found pulmonary syphilis in four (0 3 per cent) In a series of 2 880 necropsies, 314 of which showed lesions due to syphilis, Symmers found evidence of pulmonary syphilis in twelve—an incidence of 0 24 per cent

* From the Department of Internal Medicine University of Cincinnati College of Medicine
* Read before the Section on Practice of Medicine at the Seventy Third Annual Session of the American Medical Association St. Louis, May 1922
1 Osler (quoted by Land)

Such figures give convincing testimony as to the rarity of the classical forms of pulmonary syphilis. On the other hand, Watkins reports that of 6,500 roentgenologic examinations of the chest, the diagnosis of pulmonary syphilis was made in 172 cases (2.6 per cent.). But it is to be pointed out that the diagnosis of pulmonary syphilis by means of chest plates alone

1



2

Fig. 1 (Case 1).—Condition, May 31, 1920. Density of right middle lobe and upper part of right lower lobe with marked fibrous changes at the right base; shadow indicative of gumma with fibrosis; definite knobby deposits in left hilum with peribronchial thickening over middle and lower portions of left lung.

Fig. 2 (Case 1).—Condition, Aug. 27, 1920. Definite decrease in density in right middle lobe and upper part of right lower lobe; marked fibrosis over entire right side; left lung unchanged.

is not justified by the present state of our knowledge. Therefore the figures of Watkins as to the incidence of pulmonary syphilis, much higher than those of all the other series, must be taken with reserve. Attention should be called to the fact that French and Italian writers have described pulmonary lesions due to syphilis other than the classic type. Balzer has recently reported cases of syphilitic bronchitis with demonstration of spirochetes in the sputum. Such forms have not been described in America as yet. But the proneness of syphilis to attack the mucous membranes of the mouth, nasopharynx and larynx makes the assumption of syphilitic bronchitis at least plausible. The rapid improvement of these cases on antisyphilitic treatment alone also adds weight to the presumptive diagnosis. It may be that such lesions might occur in the secondary stage of syphilis as well. It would appear worth while to devote further study to this phase of the question.

3

4

Fig. 3 (Case 1).—Condition, Nov. 4, 1920. Density on both sides has decreased to a considerable extent; all evidence of gumma has disappeared.

Fig. 4 (Case 1).—Condition, Nov. 20, 1920. Some peribronchial thickening and some fibrosis in both lung fields; no evidence of pulmonary tuberculosis.

In a careful analysis of 120 cases taken from the literature, Karschner found pulmonary syphilis more common in males than in females, the ratio being 2 : 1, though the condition seemed more fatal to women than to men. The average time of appearance of pulmonary syphilis after the initial lesion was eleven years.

Excluding the congenital white pneumonia from discussion again, the commoner anatomic lesions are the gumma and the fibroid indurative processes. Secondarily, syphilitic bronchiectasis is not infrequently found, more rarely ulcerative and gangrenous lesions.

Gummas may be single or multiple, and may vary greatly in size. The softening of a gumma and the erosion into a bronchus may produce cavities which on superficial examination resemble the picture of pulmonary tuberculosis. Gummas are found more often about the hilum and in the lower lobes than elsewhere.

The studies of Warthin have shown that the gumma is not as common in pulmonary syphilis as is the low grade inflammatory process with subsequent fibroid induration. These indurative processes begin at the hilum and extend outward along the bronchi and blood vessels. Large areas of dense fibroid induration may thus be formed, and many cases of pulmonary fibrosis with bronchiectasis may have their origin in this way.

In addition to these commoner forms, Landis and Lewis have described cases in which the lesion consists of an area of consolidation and catarrh around the lung root or extending to the apexes. It has generally been held that the apexes of the lung are not invaded by the syphilitic process, but recent evidence, as

5

6

Fig. 5 (Case 2).—Condition, Sept. 18, 1920. Marked density over upper and middle right lobe with fibrosis in lower right lobe; increase in density in the left hilum region; moderate peribronchial thickening of the left lung field; no evidence of gumma.

Fig. 6 (Case 2).—Condition, Dec. 5, 1920. Density over the entire right lung area; fibrosis of left lung field as before.

gathered by the French school, has shown that the lung apexes do not escape the syphilitic process.

There are no characteristic symptoms of pulmonary syphilis. Cough, with or without hemoptysis, dyspnea, night sweats, loss of weight and moderate fever may all be present. Janeway first called attention to the frequency of fever, night sweats and loss of weight in pulmonary syphilis, and it was he who noted the fact that the pain in the right side of the chest in these cases is not due to pleurisy but to syphilitic perihepatitis.

When syphilitic mediastinitis complicates the picture of pulmonary syphilis, severe substernal pain with dyspnea, irritative cough and hoarseness, and evidence of circulatory obstruction are likely to be present.

There are no physical signs distinctive of pulmonary syphilis. The signs present are those to be expected with consolidation, fibrosis, bronchitis or bronchiectasis.

It is thus apparent that the diagnosis of pulmonary syphilis presents distinct difficulties.

With the symptoms and physical signs of tuberculosis, with repeated sputum examinations persistently negative for tubercle bacillus, with a positive Wassermann reaction, the diagnosis may at least be suspected. Roentgen-ray examination offers valuable confirmative

evidence, because the chest shadows in pulmonary syphilis differ in some degree from those of tuberculosis In some cases, the chest shadows may be said to be almost distinctive of syphilis Once the suspicion of pulmonary syphilis is entertained, intensive antisyphilitic treatment is called for And if, under such treatment, marked improvement in the general condition and decided clearing of the chest shadows should occur, the diagnosis may be considered established But there are several points that call for special emphasis in this connection In the first place, syphilis and tuberculosis may coexist in the same lung In such cases, arrest of the syphilitic process may occur under antisyphilitic treatment, the tuberculosis remaining unchecked In the next place, certain cases of pulmonary syphilis do not respond to antisyphilitic treatment, and, finally, some cases of pulmonary syphilis clear without any antisyphilitic treatment

It is the purpose of this paper to record the results of a study of all the patients admitted to the Cincinnati Tuberculosis Sanatorium (a municipal institution) during a period of two years All grades of tuberculosis are, of course, admitted to the institution About 65 per cent of all the cases belong to the far advanced group of the National Tuberculosis Association classi-

7

8

Fig 7 (Case 2) —Condition Feb 9 1921 Upper and middle right lung clearing to clear right lower clearer than before left lung field clear
Fig 8 (Case 2) —Condition March 27 1921 Density over entire right side greatly diminished left lung field normal heart shows enlargement of all diameters of the aorta and also of the transverse diameters of the heart with aortic configuration

fication During the years 1920-1921 there were 791 adult patients admitted to the sanatorium Of these, 609 (77 per cent) were white, and 182 (23 per cent) were colored Though the colored patients constituted but 23 per cent of the total hospital census, 33 per

ANALYSIS OF WASSERMANN TESTS BY RACE

	Per Cent
Colored patients in hospital	23
Deaths among colored patients	33
Colored patients dead with positive Wassermann test	27

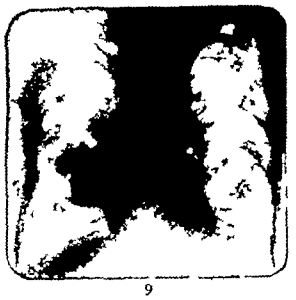
White patients in hospital	77
Deaths among white patients	67
White patients dead with positive Wassermann test	11
White patients living with positive Wassermann test	11

cent of all the deaths during the two year period occurred among the colored patients Analysis of the Wassermann tests, taken as a routine on all patients on admission to the sanatorium, showed that 13 per cent of all patients living had positive blood Wassermann tests, 17 per cent of all patients dying had had positive Wassermann tests Figures of the Wassermann tests are analyzed by race in the accompanying tabulation The higher death rate and the higher positive Wassermann test in the colored race are, of course, in conformity with general experience In this series of 791 cases, the diagnosis of pulmonary syphilis was made in four (0 5 per cent) Curiously enough, all four cases occurred in white patients, three men and one woman The diagnosis of pulmonary syphilis was not made in any of the 182 colored patients



9

10

Fig 9 (Case 3) —Condition May 3 1920 Marked fibrosis of the entire right side with the exception of the extreme base Knobby deposits at the left hilum peribronchial thickening of the entire left lung field typical syphilitic aortic shadow
Fig 10 (Case 3) —Condition Nov 14 1921 Density on right side has decreased very markedly Left lung also much clearer than it was some fibrosis still evident on both sides

The woman with pulmonary syphilis died, she had a combination of pulmonary tuberculosis and syphilis The three men recovered, two under intensive antisyphilitic treatment, the third without such treatment

In addition to these four cases two other cases of pulmonary syphilis from the wards of the Cincinnati General Hospital are reported One of these occurred in the service of Dr M A Brown, the other in my own

REPORT OF CASES

CASE 1—B K, a white man, aged 42, presented physical signs on admission confined to the upper part of the right lung The sputum was persistently negative The Wassermann test was positive on admission, May 10, 1920, and also in July August and November It was negative in January, 1921 Antisyphilitic treatment was begun shortly after admission in May 1920 Twenty-four doses of neoarsphenamin were administered in the course of ten months The patient is in excellent condition at present

CASE 2—C M, a white man aged 58, admitted to the sanatorium Sept 11, 1920 presented physical signs rather atypical for tuberculosis The sputum was repeatedly negative for tubercle bacilli Complement fixation for tubercle bacilli was positive The Wassermann test was positive on admission The first dose of neo arsphenamin was given, November 30 Between this date and Jan 5 1921 the patient was given five doses of neo arsphenamin The Wassermann test was negative in September 1921 During the administration of the drug, definite cavity signs appeared in the upper right lobe The temperature was irregular, varying from 97 to 102 F

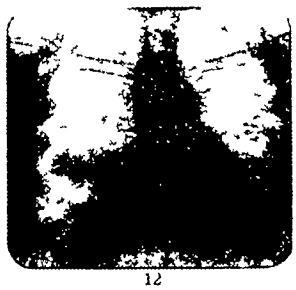
Fig 11 (Case 4) —Condition June 14 1920 Bronchostenosis with collapse of entire left lung indicative of syphilis moderate peribronchial thickening on the right side

CASE 3—J S, a white man, aged 62, presented physical signs which were not those of advanced tuberculosis on admission April 19, 1920, but the first roentgenograms taken, May 5 revealed very marked densities in the right lung field especially On admission the sputum showed tubercle bacilli, but repeated examinations thereafter were persistently negative and have remained so On admission, the Wassermann

test was positive The patient was put on the ordinary sanatorium regimen No antisyphilitic treatment was given

CASE 4—N B, a white woman, aged 53, apparently presented the coexistence of advanced pulmonary tuberculosis and syphilis The sputum was constantly positive, as also was the Wassermann test The patient was given antisyphilitic treatment in addition to the regulation sanatorium regimen She never showed any improvement, and the roentgenogram taken some time before death shows the peculiar involvement Unfortunately, no necropsy could be obtained

CASE 5—J R, a colored man, aged 49, was admitted to the Cincinnati General Hospital, June 29, 1918, with the diagnosis of cardiac hypertrophy and dilatation aortic insufficiency, and syphilitic aortitis The chest examination gave



12

13

Fig 12 (Case 5)—Condition July 5 1918 Gumma of right middle lobe extending outward from hilum area with marked peribronchial thickening and fibrosis some knobby deposits in left hilum area typical syphilitic aortic shadow, enlargement in all diameters of the heart aortic configuration

Fig 13 (Case 5)—Condition, Aug 8 1918 Density over entire right side, shadow of gumma still present the density on the right side is caused by thickening of bronchus with resulting collapse of the lung

evidence of consolidation on the right side The Wassermann test was positive Despite rest, cardiac stimulation and vigorous antisyphilitic treatment the patient continued to grow worse and died seven weeks after admission Roentgenograms were taken shortly after admission and shortly before death

CASE 6—J B, a colored man, aged 44, was admitted to the medical service at the Cincinnati General Hospital, March 4, 1922, with the diagnosis of aortic insufficiency, mitral insufficiency, cardiac hypertrophy and dilatation, and syphilitic aortitis In addition to the physical signs dependent on his cardiac condition, this patient showed areas of consolidation (on physical examination) in the right middle and left lower lobes The Wassermann test was positive The first roentgenograms taken confirmed the suspicion of pulmonary syphilis In the last two months this patient has had ten injections of neo-arsphenamin in addition to treatment for the cardiac condition At present the patient's general condition is improved, though during his stay in the hospital a right hydrothorax developed But repeated roentgen-ray examinations have revealed that there has been no change in the chest condition as yet

ABSTRACT OF DISCUSSION

DR HARLOW BROOKS, New York Dr Friedlander has called attention to a condition which is rather more frequent than most of us realize I never realized this until I became pathologist in a service consisting of tuberculous cases Statistics do not give a good rating of this, because it is only when one gets 100 per cent of necropsies that one can be reasonably sure of getting all cases Of course, most cases usually occur in the tuberculous wards, not in the acute ones but particularly among those cases which are termed incipient Dr Friedlander put special stress on the cases of bronchitis One should bear that in mind, and when one has a chronic persistent case of bronchitis, try the therapeutic test, and, of course the Wassermann test We noted the frequent association of cardiovascular lesions with pulmonary lesions When we found cardiovascular involvement, we looked, but frequently in vain, for pulmonary involvement Sometimes we found it only at the necropsy Only when a patient had been in the ward for some time and had been found negative, as far as tuberculosis is concerned, were our suspicions aroused It takes a hardy diagnostician to make a diagnosis of syphilis of the lung on the first examination, although characteristic fluoroscopic and roentgen-ray pictures are shown The fluoroscope has been of great benefit to us, and in fluoroscopic work on the lungs one should note how frequently the mediastinal nodes are involved in these cases, particularly about the hilum Unresolved or delayed resolution in pneumonia is more often of syphilitic origin than we think That is what excuses the treatment of delayed resolution by the iodids We found that many of these delayed resolutions in pneumonia were specific and cleared up under the iodids The greatest difficulty has been in the differentiation between neoplasms and syphilis of the lung Usually considerable time must be given before one can do this, and one must resort to the therapeutic test

DR KENNON DUNHAM Cincinnati Dr Friedlander has shown cases with abnormal densities on the roentgenogram and with a definite Wassermann reaction The patients were treated for syphilis and recovered, others of the same type treated for syphilis did not recover, others of virtually the same type recovered without treatment Until we know the pathologic picture of syphilis of the lung, we are going to be misled Almost every clinician finds these changes, and many of them clear up Some of the most brilliant cures are of this type In cases showing mucous patches in the throat, localized rales will be found over the chest, but it seems to me that unless one can find the spirochete in that lung, it may lead one to false conclusions I am not criticizing Dr Friedlander, but I do not wish to convey the impression that the story of syphilis of the lung is closed by this study

DR W S THAYER, Baltimore It is exceedingly difficult clinically to recognize syphilis of the lung positively intra vitam and very rare to find it postmortem when it has been recognized intra vitam Our experience has been like that of Dr Friedlander, a certain number of instances showing roentgen ray evidences of induration about the hilum of the lung associated with signs suggesting syphilis, clearing

Fig 14 (Case 6)—Condition in March 1922 Marked fibrosis of right middle lobe moderate fibrosis of upper part of left lower lobe some fibrosis at right base heart configuration cardiac hypertrophy and dilatation double mitral and aortic configuration increase in all diameters of aorta

Fig 15 (Case 6)—Condition in May, 1922 Only slight decrease in density of right middle lobe increase in density at right base fluid level left side unchanged

up under antisyphilitic treatment Other instances—in our experience rather commoner—have been instances of syphilis of the bronchial tree or trachea with ulceration and stenotic changes An example of what we meet clinically was a woman who came to the outpatient department complaining of cough and fever She showed large serpiginous ulcers on the arms and abdomen and signs of infiltration on the upper part of the right lobe and a rather scanty roentgen-ray shadow starting from the same area, the ulcers healed immediately under antisyphilitic treatment, and the shadow almost completely cleared up You cannot prove that the changes in that lung may not have been the remains of an influenzal bronchopneumonia, but they may have been syphilitic

OBSERVATIONS ON FRACTURES OF THE MANDIBLE*

ROBERT H IVY, M D, D D S
PHILADELPHIA

Probably no fracture in the body is less understood or, as a general rule, worse treated than fracture of the mandible The usual information given in surgical textbooks as to the practical management of these cases is vague, and consequently the surgeon, when confronted with a fractured lower jaw, is usually at a loss what to do He either attempts to treat it with a head bandage, or passes the responsibility to a dentist with the request that a splint be made Occasionally, and worst of all, he tries direct fixation of the fragments by plating or wiring For these reasons, among others, it has been considered timely to report some observations made in thirty-one consecutive cases of fracture of the mandible recently under our care at the University of Pennsylvania

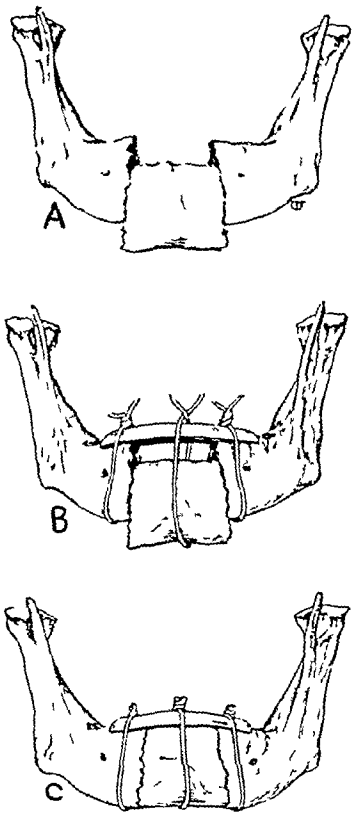

Fig 1.—*A*, Bilateral fracture in edentulous mandible *B*, circumferential wires and splint *C* circumferential wires tightened bringing symphysis fragment up into position

Of thirty-one cases, twenty-nine were in men and two in women

LOCATION

The location of the fracture in eleven of the thirty-one cases, 35 5 per cent, was bilateral One case presented two fractures on the same side Thus, there were nineteen cases of single fracture and twelve of double, making a total of forty-three fractures in all The location was mental foramen region, sixteen, or 37 2 per cent , angle, eleven, or 25 6 per cent , incisor region, eight, or 18 6 per cent , molar region, six, or 14 per cent , neck of condyle, two, or 4 6 per cent

In the majority of bilateral cases the fracture on one side is at or near the mental foramen, and on the other at or near the angle The point of impact of the force producing the fractures is often midway between the two fractures For example, if a blow is received to the right of the chin, there is quite likely to be one fracture at the right angle and the other to the left of the chin Thus, fracture by indirect violence occurs just as frequently as by direct violence In every case of fracture at or near the mental foramen, one should always look for another at the opposite angle It will be found in about 60 per cent of the cases The more marked symptoms of the fracture near the mental foramen may cause the fracture at the opposite angle to be overlooked It is surprising how often these injuries are undiagnosed

RELATION OF TEETH TO THE FRACTURE

In this series, thirty-two fractures were in the vicinity of teeth In only four of these were teeth in the line of fracture removed immediately It was necessary sooner or later to remove such teeth in 50 per cent of the cases These teeth frequently are of great temporary value in maintaining reduction of fragments or as points of attachment for wires This consideration, on the one hand, must be carefully weighed against the possibility of infection, on the other

EXTERNAL DRAINAGE AND SEQUESTRUM FORMATION

Of thirty-one cases, seven, or 22 5 per cent, required external drainage on account of suppuration The same number developed sequestrums requiring removal either intra-orally or extra-orally

FIXATION OF FRACTURE

There is nothing original in the methods of treatment employed in this series We have adapted well established methods as seemed best for the individual case

Of thirty-one cases, in twenty-seven, or 87 1 per cent, fixation was secured by wiring the upper and lower teeth together

One case, at the symphysis with practically no displacement, was treated by a simple metal cap splint

In one edentulous case, fixation was secured by direct plating of bone fragments through external incision

Two edentulous cases were treated by the vulcanite saddle splint combined with circumferential wiring of the bone

Gilmer,[1] some years ago, pointed out the value of wiring the lower to the upper teeth in fixation of fractures of the mandible The main object of employing any wiring method is avoidance of the difficulties and discomfort of impression taking and the delay in preparing interdental splints from these impressions Other advantages of wiring are that there is no thickness of metal between the upper and the lower teeth, and the latter are not covered so that the state of the occlusion is under direct observation at all times, if, during the course of treatment, it becomes necessary to remove a tooth, this can be done with less disturbance when the fracture is fixed with wiring than if a splint be cemented to the teeth Our records show that in the vast majority of fractures of the mandible occurring in civil life it is unnecessary to resort to impressions and interdental splints We employ a modification of Dr Gilmer's valuable prin-

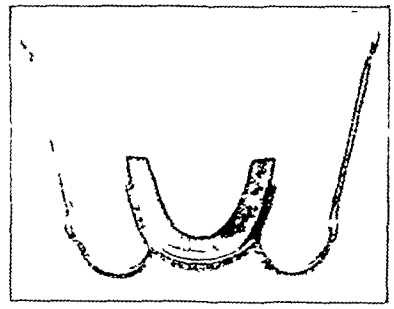

Fig 2.—Lower tray with extra-oral wires

1 Gilmer T L Arch Dentistry September 1887

ciple which permits, during the course of treatment, a ready opening of the mouth for replacement of a broken wire or for other reasons without disturbing the main attaching wires

The wire employed is either 22 gage copper wire or 24 gage brass wire In preparation of the wire to be attached to the teeth, a 6 inch length is folded around a smooth

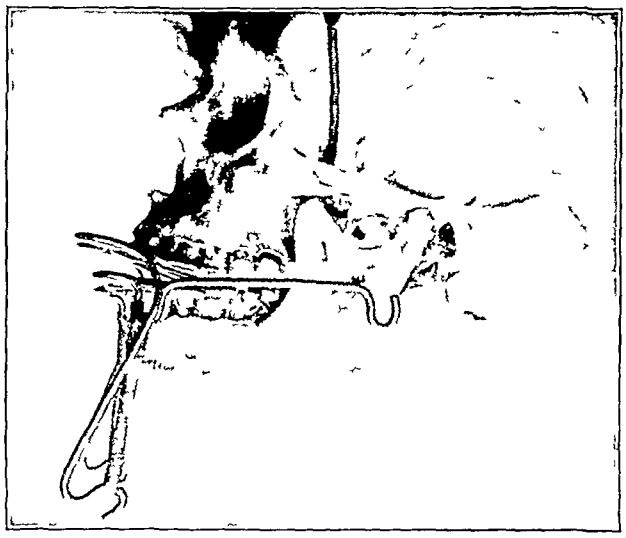

Fig 3 —Lateral view of trismus appliance mounted on skull

instrument, and a small loop or eyelet made at the middle of the strand The teeth selected to be wired are usually the premolars on each side and the central incisors If these teeth are absent or unsuitable for use as attachments other teeth are selected Both ends of the eyelet wire are passed through the interproximal space between two teeth, from the buccal side These ends are then brought back to the buccal side by passing each around one of the teeth and twisted together so that the wires will fit snugly around the teeth with the eyelet projecting from the interproximal space The ends of the wire are cut off short and bent over in order not to irritate the lip or cheek A similar eyelet is fitted to corresponding teeth of the opposing jaw and to other corresponding upper and lower teeth in other parts of the mouth Then the upper and lower eyelets at each point are connected by passage through them of a third or tie wire, the teeth are brought up into occlusion by this means and the tie wire ends twisted together, cut off short and turned in Modifications necessitated by conditions encountered in individual cases have been pointed out in the paper referred to[2]

EDENTULOUS CASES

In recent fractures the only possible indication for direct wiring or plating of the bone fragments through external incision is in an edentulous case in which there is no break in the mucous membrane and consequently the oral secretions do not have access to the fracture In as small a bone as the mandible, it is difficult to secure firm fixation by this method

CIRCUMFERENTIAL WIRING

A much better plan in edentulous cases is circumferential wiring of the bone, originally employed by G V Black[3] A vulcanite splint is first made like a saddle, to cover the lower ridge on each side of the fracture Or, if the patient has a full lower vulcanite denture, this may serve the purpose of a splint A small incision is made through the skin at the lower border of one of the fragments, and a small curved antrum trocar and cannula are passed up through this incision close to the bone on the lingual side, until the mucous membrane of the mouth is pierced. The trocar is then removed, and one end of a 16 or 18 gage silver wire is threaded through the cannula from below The cannula is withdrawn and, by means of the trocar, is passed downward from the mouth close to the bone, this time on the labial side, to emerge at the original skin opening The other end of the silver wire is then passed up through the cannula, and the cannula is withdrawn It is thus seen that the wire passes around the bone The ends of the wire are now twisted over the vulcanite splint or denture so that the bone fragment is drawn up snugly in contact with the splint Another wire is similarly passed around the other fragment and twisted over the splint The circumferential wire is well tolerated, and may be maintained for several weeks, the skin incision frequently closing without suppuration This method is particularly useful in drawing up and maintaining a central edentulous fragment in a case of double fracture (Fig 1)

TIME REQUIRED FOR UNION

Textbooks state that fractures of the mandible unite in from three to five weeks Our figures indicate that this time is considerably overestimated In this series the average time required from the date of injury to the completion of union was forty-eight days, the longest being 109 days and the shortest twenty-one days

The average number of days that fixation was maintained was forty The average time elapsing from the date of injury to the date of fixation was eight days, the longest being seventy-two days

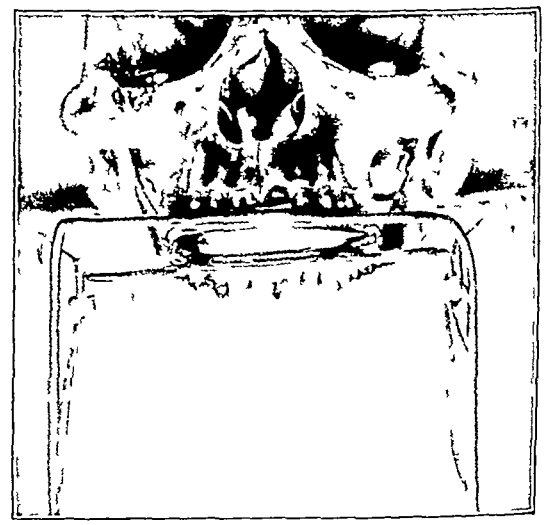

Fig 4 —Front view of appliance

It is difficult to prove by figures that early fixation will shorten treatment, because so many other factors must be considered, such as the amount of original displacement, injury to teeth, and infection The same applies also to relative time of union as between single and double fractures In our series the average time for union after fixation for single fractures was thirty-seven days, and for double fractures 43 3 days

2 Ivy R H Practical Method of Fixation in Fractures of the Mandible Surg Gynec & Obst 34 670 (May) 1922
3 Blair V P Surgery and Diseases of the Mouth and Jaws St Louis C V Mosby Company 1918

RESULTS OF TREATMENT

Results were satisfactory in all cases in this series That is, firm union was obtained with restoration of the original occlusion of the teeth When teeth were lost as the result of the injury or previously absent, the patients were discharged with the jaws in such a condition that artificial dentures could be satisfactorily applied

TRISMUS

Trismus, or temporary limitation of the opening of the mouth, is a frequent complication of fractures of the mandible owing to muscular contracture and infiltration with inflammatory exudate This limitation will usually disappear in the course of time, following ordinary exercise, but it can be overcome much more rapidly by the use of a dilator which we have had made This appliance is universal, i e, it does not have to be made especially for the individual case, it is easily fitted in the mouth by the patient or some one in the house with him, and it is practically as stable as an apparatus that has been made from dental impressions of the individual The construction is extremely simple, the two parts being flat metal trays passing between the occlusal surfaces of the upper and lower teeth (Fig 2) The trays can be inserted through a space of less than 1 cm between the upper and lower incisor teeth To the outer sides of each tray are soldered heavy wires, which pass out of the mouth and curve backward over the cheeks like Kingsley splints The wire attached to the upper tray on each side turns down at a right angle about opposite the premolar region, and ends in a hook about 3 inches lower down The wire attached to the lower tray passes directly backward, and is provided with a hook at a point opposite the downward turn of the upper wire The dilating force is a heavy elastic band placed between these hooks on each side (Figs 3 and 4) This application of dilating force in the manner described is original with Darcissac[4] of Paris, who, however, made individual apparatus from impressions in each case, casting metal caps to fit the teeth The elastics produce a constant counteraction to the powerful elevator muscles of the mandible, which at the same time are permitted to function, the upper and lower jaws being at no time fixed Lateral movements as well as opening and closing are possible The dilating force can be readily regulated by the size and tension of the elastic bands This appliance is useful not only following fractures, but also in limitation following any other cause, or as an adjunct after operations for ankylosis It can be worn for fifteen or twenty minutes every few hours, and can easily be taken out and put in

Prevention of Delinquency—The National Committee for Mental Hygiene through a recent gift from the Commonwealth Fund has been enabled to establish a new department to be known as the Division on the Prevention of Delinquency This division will furnish psychiatric service to a limited number of juvenile courts throughout the country free or on a cost-sharing basis when requested The selection of courts will depend largely on the interest shown and the prospects for the establishment of a permanent clinic at the expense of the community A demonstration clinic including a psychiatrist a psychologist and a psychiatric social worker will be assigned to each court to which it is possible to render such aid—*Mental Hygiene* January 1922

TREATMENT OF NONUNION OF FRACTURES OF MANDIBLE BY FREE AUTOGENOUS BONE-GRAFTS*

FULTON RISDON, M D
TORONTO

The indications for bone-grafting of the mandible are nonunion of fragments of long standing, to replace lost bone due to gunshot wounds, carcinoma, infection, cysts, etc, provided enough of the ascending ramus is in situ or to protrude the mandible when the mental process is deficient

The preliminary steps may be thus summarized The patient is examined to ascertain that all infection has been cleared up for at least five months, and that there are no teeth adjacent to the ends of the fragments The roots of the teeth are always a menace to the graft, and, unless they are removed, sufficient bulk of the graft cannot be inserted If it is found necessary to remove any teeth in this area, the operation should be deferred for two months Of course, there are exceptions to this rule, one being when only one tooth remains in the posterior fragment, but in this case greater care is taken at the time of the operation to see that the root area is not included in the bed for the graft A consultation should now be had with one's dental colleague if not before, as to the desirability of the type of splints to be used, and as to the width of the desired arch of the mandible A modified Hammond splint has been used by our colleagues Drs Campbell and Gordon, with a pin and tube attachments for locking the lower to the upper jaw, and the metal of choice has been Victoria metal, supplied by Claudius Ash, Sons & Co, of London, England Any metal which, after it has been cast, has still some temper and is strong, meets all the requirements We have used coin silver with equally good results, but care should be taken in the casting that the baser metals are not lost Should this occur, it is easily detected, as when the casting is pressed over the teeth the splints spread at the widest part of the teeth and do not grip at the cervical margin

These splints are cemented with Ames copper cement four days previous to the operation, and the pins are inserted in the tubes on the second day

The diet of the patient must, of course, be changed, and he is placed on a semisolid diet, including soups, mashed potatoes, minced meats, egg-nogs, junkets, etc, and one bottle of stout a day These patients do not lose weight but, of course, are not working

The right or left hip is prepared by the nurse the day before, as the bone selected by us is always taken from the crest of the ilium We have used the rib with success, and also the tibia, but prefer the ilium for the reasons that it is very easily and quickly obtained, it is more cancellous than either of the bones named above, and greater bulk of bone can be obtained We assume to a large extent that the theory of absorption of the entire graft and its replacement later by bone-forming elements, as outlined by Gallie and Robertson, is the accepted theory of bone regeneration If we accept this, the more cancellous the selected bone is, con-

* In this work Dr Carl Waldron now of Minneapolis was associated with the author

* Read before the Section on Stomatology at the Seventy-Third Annual Session of the American Medical Association St Louis May 1922

sistent with its strength, the greater proportion of successes should follow its use, and this we have found to be a fact in actual practice

The type of anesthesia employed is of considerable importance, as the anesthetist must at all times after induction be some distance away from the field of operation We prefer the intratracheal, in which a catheter is passed under direct vision between the cords into the trachea, and the anesthetic given by a machine, such as the Connell We have also used rectal anesthesia, but discarded it after seeing the advantages of the intratracheal method Anesthesia is induced much more rapidly, and the patient recovers more quickly and is more under the control of the anesthetist We have not attempted any operations under local anesthesia, although we know it could be used, but we feel that this is too important an operation for that type of anesthesia, as the patient might interfere at any moment

The technic of the operation is most exacting, and in no other field of surgery is it more so I believe that the entire success of the operation, having previously excluded infection, depends on this most exacting, tedious, excellent technic

The first step must exclude the mouth, and this is done by placing a sterile piece of rubber dam parallel with the lower border of the mandible, some distance from the line of the incision, and held in position by adhesive tape When this is turned back it covers the mouth and prevents moisture from soaking through the towels The neck is now cleansed with pure alcohol, continued for fifteen minutes After the incision has been made, as a rule about 4 or 5 inches long, the scalpel is discarded for another and the wound completely walled off by towels with clips Under no circumstances is the gloved hand permitted to come in contact with the wound, sutures or sponges This is all done by freshly sterilized instruments, even to the tying of ligatures This is known as the nontouch technic or bone-technic, introduced by Sir Arbuthnot Lane We had the privilege of very close association with him during the war, and we feel deeply indebted to him for his kindness and patience in teaching us his methods

The hip area is prepared in the operating room again, with alcohol, the same technic being observed, and the bone is obtained by a chisel and a mallet We discarded the electric saw, because we felt that it burned the bone owing to the rapid revolutions of the small circular saws, and in this way destroyed the bone-forming elements If water was used to overcome the resultant heating, moisture gained access to our wound and soiled our towels We prefer bone rongeurs, hand drills and the more laborious methods, as they have given better results in our hands We prefer a square butt joint if possible, and use Belgium iron wire to hold the graft in position These wires are not removed, and no drainage is placed in the neck wound but is inserted in the hip area The wound is closed with metal clips rather than sutures, and the splints left in the mouth for three months

In our clinic seventy operations were performed, resulting in sixty-six successful bone-grafts four failures, and no deaths, an average of 90 per cent of successes In the last two years we have done twenty-one, with one failure, and that failure was due to an opening into the mouth at the time of the operation

30 Avenue Road

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS IVY AND RISDON

DR CARL W WALDRON, Minneapolis—Dr Ivy has presented a practical means of treating most of the simple fractures of the mandible, I think he has largely overcome the difficulty many had in the method of wiring the teeth In our war work the splint which Dr Risdon has shown served admirably but in civil practice on account of the lack of trained technicians, I feel that Dr Ivy's methods are better With reference to his views that certain teeth must be temporarily retained, to prevent loss of a fragment I cannot agree We followed that practice in our Canadian service for years The British service was radical We saw later many nonunions in which we felt that we would have secured good strong union with our methods With reference to bone grafting, I agree with Dr Risdon that the iliac crest is preferable Before I left England I saw some 100 bone grafts of the mandible clinically Many had splints in place which did not prevent manipulation I was convinced those cases treated by iliac crest grafts were by far the most successful grafts The graft advocated by the Frenchmen has certainly a place, particularly where there are thin fragments without a basis for an iliac crest graft, in such cases I feel that the osteoperiosteum graft has a place

DR WILLIAM S BAINBRIDGE, New York In the navy we have not had as good results as we hoped we might have with bone grafts I think it is due largely to the lack of technic and perhaps the finesse of key working which was so important Troops from India were fed on their own food to which they were accustomed because of religious belief Some of the British surgeons called my attention to a lamentable failure of healing wounds and bone repair in certain regiments Those that had poor teeth, mouth conditions bad, poor healing and repair of bones, far more nonunion and much pain were from the same part of India The British surgeons in charge of the men discerned that there was only one reason why this regiment suffered They had not brought from India the olive sticks the natives use for the cleaning of the teeth They were provided with ordinary tooth brushes which they would not use When however, the mouths were cleaned up and the men furnished with olive sticks their conditions improved and when bone was transplanted and bone repair inspected, conditions were found improved

DR F B MOOREHEAD, Chicago Success in bone graft surgery is due to certain fundamental principles, the nontouch method developed by Lane and quite equal in importance, is the securing of a perfectly well healed field, one quite free from infection Nothing should be allowed to touch the wound except a sterile instrument, the fingers should be kept out entirely After watching Dr Risdon's work I am quite converted to the use of the crest of the ilium as better material for transplanting purposes than either the rib or the tibia

DR T L GILMER, Chicago Dr Ivy has been good enough to refer to what he calls my method of wiring the teeth of the mandible to those of the maxilla in the treatment of fracture of the mandible For the last eight or ten years I have abandoned the method he credits me with, except for temporary purposes The method of wiring I now usually employ has an advantage over the older method and I think over Dr Ivy's method It consists of wiring an expansion bar such as is used by orthodontists to the buccal and labial surfaces of the teeth of the mandible and maxilla These bars are wired together by two or three small wires By this method one is able to cut the wires, holding the teeth in occlusion, every few days, so that the mouth may be opened for cleansing This is done without danger of displacement of the fragments of bone, since the expansion bar holds the teeth in alinement Fractures of the mandible occasionally occur without completely severing the periosteum and in such cases the fragments are not displaced If the patient does not use the jaw for mastication he will be better off

without immobilization The treatment of ununited fractures by bone grafts is often good practice In a few instances when other methods have failed I have employed the Cole pedicle graft with excellent results

DR FRANK J TAINTER, St Louis During the war I was connected with several clinics in which we had to treat a number of fractures of the mandible with loss of substances They were all repaired by bone grafting, the ileum graft, the rib and the pedicle graft I happen to be connected with Dr Cole who first described the Cole's pedicle graft In the treatment of fractures there are a few principles that should always be taken into consideration, first, absolute reduction, and second, immobilization No matter where you take the bone, if the fragments are not properly immobilized you cannot expect a good result following a bone graft The type of fractures we had the most difficulties with were those that left the posterior fragment with no teeth on it We feel that the graft from the ileum lent itself better to the curves and to what was expected of it than any other bone taken from any other place but our results from the pedicle graft were far better than from any free graft The pedicle graft has a good blood supply, nearly always carries with it small muscle and even in the face of infection one may secure perfect results I am quite sure the pedicle graft described was not Cole's pedicle graft Cole always insisted that whenever any bone was splinted all the bone that could be exposed should be opened up and freshened and the bone graft put in I wish to speak of the splint shown by Dr Ivy, a most ingenious thing for the correction of trismus of the jaw I think it the most perfect mechanical appliance on the market Ruggles suggested the use of a clothes pin for the same purpose and we have been successful with it In our clinic work we never had trismus following our cases

DR THEODORE BLUM New York I have been using the so-called army method for correction of fractures of the mandible since 1916 when I first saw it demonstrated by Lieutenant Graham of the U S Army in Belmont The only slight improvement which I would like to suggest to Dr Ivy's method would be that the wire should not be turned at the height or convexity of the tooth but that the wire should be placed at the interproximal space and it would then be covered by the loops

DR ROBERT H IVY, Philadelphia I have never found it necessary in any operation involving the face, mouth or jaws to use intratracheal anesthesia For these cases I employ intrapharyngeal ether introduced through nasal tubes With this method it is not necessary to disturb the intermaxillary fixation, and the mouth can be kept closed The use of wire for the fixation of bone grafts has been condemned by some authorities, but in my experience silver wire gives the greatest satisfaction and much better approximation can be obtained by twisting the wire than by using any animal suture material For the general run of cases the ilium graft is superior to any other type Other methods are indicated in special cases The pedicle graft has the advantage that it can be used with greater chance of success in the presence of infection My chief reason for employing the method of wiring the teeth in ordinary civil life fractures of the mandible is to get away from the bother of taking impressions and making splints The wiring does not necessarily fix the fracture any better than a properly made interdental splint Splints do just as well, perhaps better, when there is an organized staff to make them but it is difficult to get the work done under ordinary conditions I am quite familiar with the present method used by Dr Gilmer for fixation of fractures of the mandible, and admit its efficiency My idea is to simplify matters as much as possible so that the average surgeon can handle these cases without having to resort to special apparatus or special men to make it

DR FULTON RISDON Toronto I have used the ordinary eye that is used for ladies' dresses, wiring it around each tooth on both sides of the fracture doing the same to the teeth in the upper jaw in the region of the fracture and attaching the eyes together with silk rather than wire In handling a large number of these cases we found silk of much more service than the wire, because in our hands it did not loosen so quickly There is really nothing to this little appliance, but it has helped me with some cases In reference to the anesthetic for bone grafting, we prefer the intratracheal method In using this a catheter is placed between the cords and out between the lips, as in most of these cases some teeth are missing Under no circumstances do we use an open bite splint The interesting feature of this anesthesia is that one does not have pneumonia as a complication, at least that is our experience

Clinical Notes, Suggestions, and New Instruments

CARPOMETACARPAL DISLOCATION

EDWARD H MCLEAN, M D, OREGON CITY ORE

Cases of multiple dislocations at the carpometacarpal articulation are of sufficiently rare occurrence to warrant their being recorded for statistical reasons

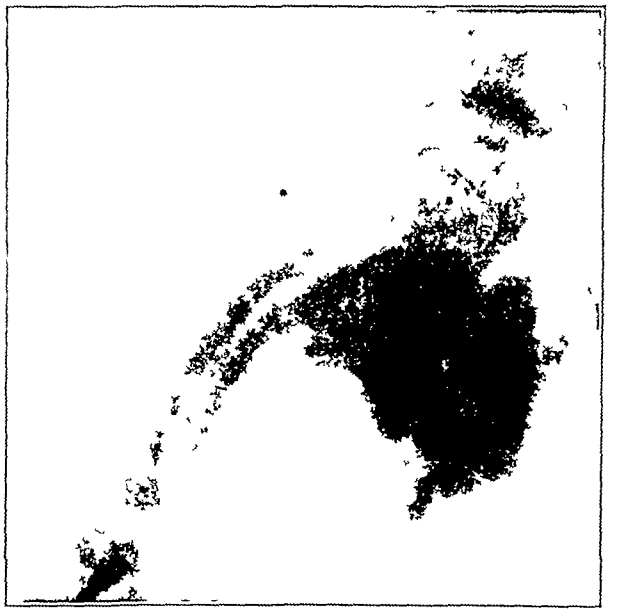

Fig 1.—Carpometacarpal dislocation lateral view before reduction

A farmer, aged 40, was injured while pulling stumps He was using a puller in which a 14 foot pole acted as a lever The chain by which two heavy farm horses were hitched to the pole parted, releasing the pole, which struck the patient on the back of the right hand, right forearm, and right lower thorax He was thrown violently to the ground, striking on the left hand with the arm outstretched

The injuries sustained consisted of fractures of several ribs on the right side of the left clavicle and of the right ulna laceration of muscles of the right forearm, laceration and contusion of the right hand, and the dislocation to be described occurring in the right hand

On account of the marked swelling of the hand, the condition was not suspected until after about a week of local treatment At this time, an unusual thickening of the wrist and hand with apparent shortening of the metacarpus, was noted Examination by roentgen ray revealed a posterior dislocation of the four inner metacarpals on the carpus with about an inch of overriding, anterior dislocation of the thumb metacarpal, with an inch of overriding, and fracture of the base of the index metacarpal

Reduction was easily accomplished by traction and direct pressure The presence of fragments of the base of the index metacarpal between it and the base of the middle finger prevented complete reduction of the former

Two years after injury, the patient has a hand that is nearly normal functionally He is unable to close the index finger completely to make a tight fist, but he can milk and do other farm work requiring the use of the finger Excision

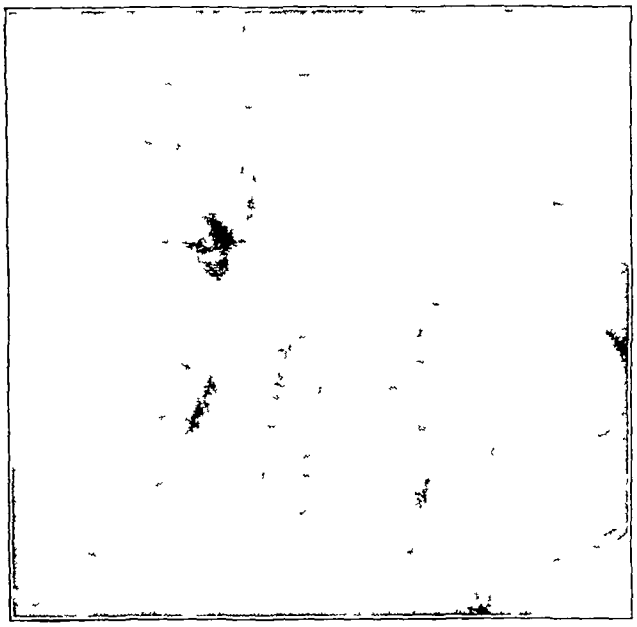

Fig 2—Carpometacarpal dislocation anteroposterior view after reduction

of the fragments of the base of the index metacarpal would have given a better result, but the patient was unwilling to submit to operation

DIRECT VISION ADENOTOME

I D KELLEY, JR M D ST LOUIS

Working on the assumption that the existing method of adenoid removal with the instruments thus far devised is

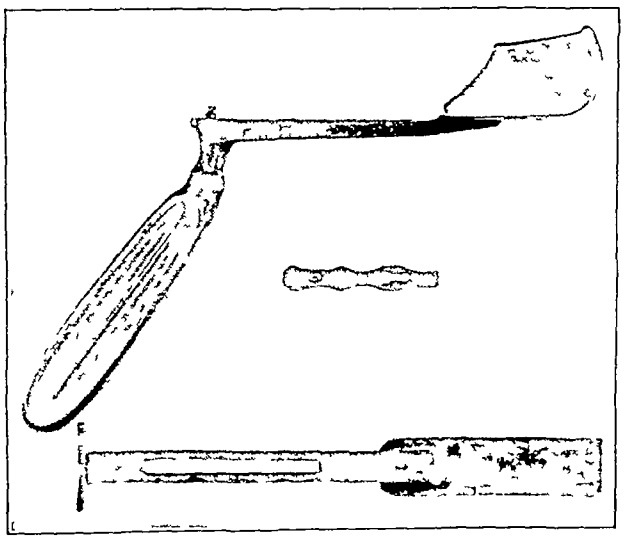

Fig 1—Parts of direct vision adenotome

unsurgical, because of the fact that to carry out this operation the operative field has not been in the direct line of vision of the operator, I investigated thoroughly the postnasal space I found it possible to construct an instrument that would not only remove the adenoid as completely as any instrument thus far devised, but also bring the adenoid area in direct vision of the operator previous to and at the time of removal, and do away with the untoward results in previously devised operations, such as blind technic, stripping of the posterior pharyngeal wall, partial adenoid removal, and loss of the removed adenoid

The principles which this instrument employs are (1) elevation of the soft palate by the oral route sufficient to expose to view the circumference of the posterior nasopharyngeal wall, and (2) a cutting blade adhering to the curvature of this wall, working from below upward, incising the adenoid from its nasopharyngeal attachment

The instrument consists, as seen by the accompanying illustrations, of a hood or soft palate retractor, the distal or blade end of which, when put into position, conforms to and rests directly against the postnasopharyngeal wall This is attached to a steel shank, from the proximal end of which extends a hand grip at such an angle as to prevent chin or chest interference when gripped and placed in position On the upper surface of this shank is placed a steel shaft, to which is attached at its proximal end a thumb pressure plate, and to its distal end by means of an eye and post a flexible steel blade running in two slots on either side of the distal end of the hood, traversing the surface from below upward and held in position on the shank by a steel clamp

The instrument is to be used in conjunction with either indirect illumination (as seen in the illustrations) or direct illumination, when so desired, by placing a small electric

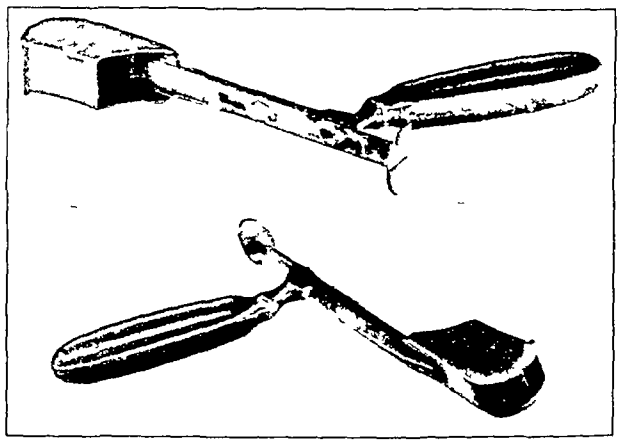

Fig 2—Two views of instrument assembled

lamp in the upper inner surface of the hood, carrying the wiring along the under surface of the shank and out through the end of the handle

TECHNIC FOR USING THE INSTRUMENT

Under local or general anesthesia, the mouth is widely opened with a gag and the instrument introduced through the oral cavity under the lower border of the soft palate The distal end of the instrument is then elevated behind the soft palate until the upper surface of the hood assumes a plane corresponding to the angle of the vault of the nasopharynx with the posterior wall It is then gently pushed into approximation with the posterior wall, whereupon the adenoid will be in full vision of the operator In this position, by means of the thumb plate, the blade is pushed home the instrument removed, and, inside the hood, producing when the blade is closed a cup, will be the adenoid, severed from its postnasal attachment

The instrument is to be made in several sizes corresponding to the dimensions of the nasopharyngeal space in persons of varying ages

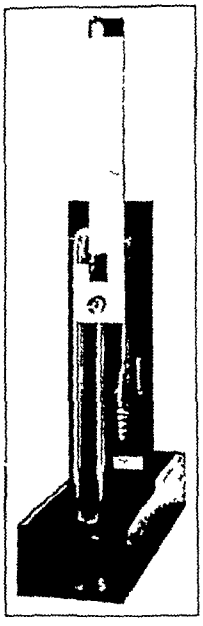
608 Humboldt Building

State Aid for Crippled Children—Backed by 460 rotary clubs in Ohio, legislation has been enacted providing first for treatment of all crippled children at state expense and secondly for the establishment of special schools and classes for crippled children the state allowing $300 per child

FOLDING SPHYGMOMANOMETER

PHILIP A SHEAFF M D PHILADELPHIA

The apparatus here illustrated is simple, dependable and readily portable The scale registers from 0 to 300 mm The apparatus is susceptible of refined adjustment and has the upper half of the glass tubing permanently attached It folds up, having no rubber washer to get lost or wear out, the joint being a ground one composed of steel automatically closing the exit of mercury when not in use Consideration of varying capillarity in the surfaces of the mercury is eliminated, as the two surfaces are the same diameter



Folding sphygmo manometer

CONVENIENCE

The apparatus can be readily carried in a coat or hip pocket, and when it is not in use it may be maintained in the upright position in any book case, although it may be placed in the recumbent position without disaster, if one is careful

When closed, it is held shut by a spring lock, and measures 1⅝ by 2¾ by 8⅞ inches

The instrument here illustrated and described is home made but for practical service has given me much satisfaction

4006 Baring Street

HEAD REST FOR GANGLION OPERATION*

ALFRED W ADSON M D AND GEORGE G LITTLE M E
ROCHESTER MINN

A head rest for use in a ganglion operation should be easily adjusted and applied to the head, and at the same time hold the head firmly during the operation without producing undue pressure on any particular part of the head Such a head rest (Figs 1 and 2) has been developed and used satisfactorily in many ganglion operations The head rest may be slipped on a Balfour operating table, but if the distance between the bar arms is varied (*M*, Fig 1) it will fit any operating table it is adjusted with two universal joints so that the head can be raised, lowered, or tilted from side to side as the surgeon desires It is especially designed to support the patient's head gently yet securely, during a ganglion operation in such a manner that the field of operation is wholly unobstructed

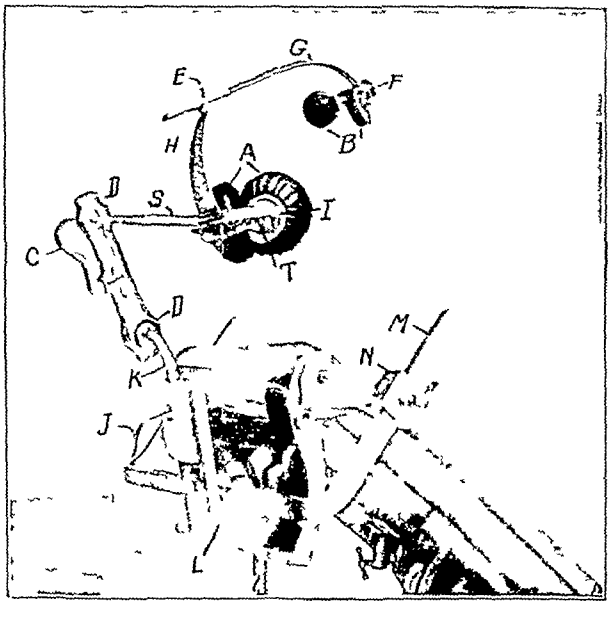


Fig 1.—Ganglion head rest attached to a Balfour table

In Figure 1 the two pads *A* are secured to a common cross bar and swivel on their respective centers, *T*, while the bar is supported at the ends by pins *I*, this allows the head piece a free swinging movement at *I* while holding the head securely Arm *H* is secured rigidly to the cross bar, and supports the adjustable arm *G*, which is locked in position by screw *E* The two front pads *B* are supported on short adjustable arms and locked in position by screw *F* The forked arm *S* and the arm *K* have ball terminals fitted into sockets *D* and *D* and are locked by movement of the handle *C* The handle *J* locks the arm and block *K* in position on the slide *L* Slide *L* is adjustable along bar *M*, which in turn is secured to and locked in position on the side bar of the table by block *N*

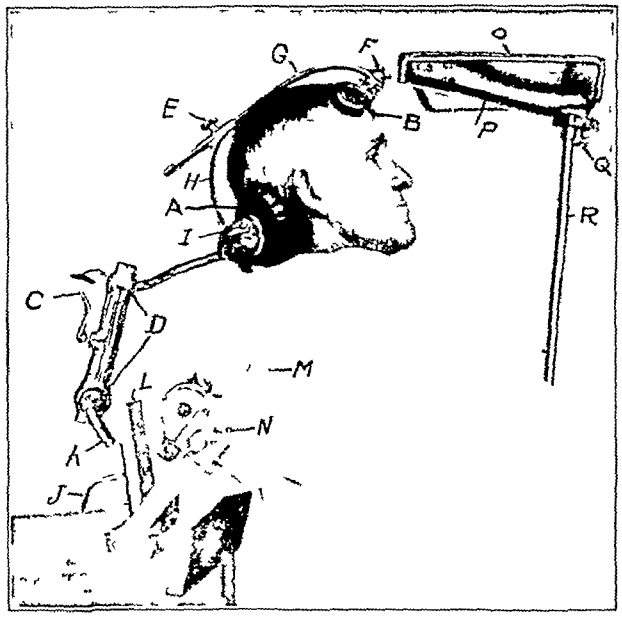

Fig 2.—Patient in position with head securely supported

Figure 2 shows the patient in position with the head securely supported The instrument tray and stand, attached to the side of the Balfour table, are adjusted to hold the towels away from the patient's face, and to leave ample room for the anesthetist

Nutrition Classes in Rochester a Success—According to a report recently made public by Dr Herman J Norton, the nutrition class in the Rochester public schools has accomplished excellent results All the nutrition classes gained better than an average of 285 per cent of the normal rate of gain The average normal gain of a boy or girl in grades three to eight inclusive, ranges from one-half to three-fourths pound (0.23 to 0.34 kg.) per month, in the nutrition classes it was not unusual for the children to gain from 2 to 3 pounds (0.9 to 1.3 kg.) in weight in thirty days These classes were run on the plan devised by Dr Emerson of Boston Enough nutrition classes have been established in Rochester to care for 7000 children A half-pint bottle of milk a day was provided for all children who were 4 per cent or more below average weight for height and who were unable to buy milk themselves The report states that this milk was an important feature of the work

WHY DOES THE TUBERCULOSIS DEATH RATE FALL SO RAPIDLY?

It is well known to sanitarians, says Haven Emerson, that the death rate from tuberculosis in the United States, in Great Britain and in Germany had been falling in a fairly uniform manner from a time earlier than Koch's discovery of the tubercle bacillus till the outbreak of the World War This has made some thoughtful persons doubt the assertions of public and private health agencies that reduction of tuberculosis has been largely due to, or at least has been very materially increased by, the campaigns of education and enforcement of early diagnosis, notification, early treatment, segregation, pasteurization of milk, infant welfare, and correction of malnutrition The effect of these various influences has been analyzed in detail by a recent writer [1]

Some evidence has been published tending to show that where the education and the organization of a community to prevent tuberculosis have been thorough, and where the conditions of housing, industry and economic independence have been favorable, the death rates from all forms of tuberculosis have fallen more rapidly than they have elsewhere, even taking into consideration all factors of age, sex and race composition of the communities concerned This applies more particularly to the large populations of the United States, Great Britain and Germany In France, in contrast, there has been not only a high tuberculosis death rate, but a rate which remained at a fairly uniform level over a long period up to the outbreak of the war In France, however, the tuberculosis death rate has fallen considerably in Paris, from 437 in 1887 to 328 in 1914, so that the stationary death rate for France depends on the absence of any fall at all in the small communities of that country, presumably because conditions of life and sanitation have remained relatively unaltered

Since 1914, in the United States and in New York City, there has been so great an increase in the rate of decline in the number of deaths from tuberculosis that it is important for us to consider what have been the dominant factors of the many possible causes of such a phenomenon It is at once obvious that if these factors can be brought under control and duplicated elsewhere or their action made continuous or permanent, we can foresee the eradication of tuberculosis as a disease of importance within the next twenty years in this country, and, again, that while there are not only great suffering and formidable losses from the disease, and the public is spending large sums to protect itself and deal generously with those already attacked, it is the special duty of public and private agencies engaged in combating the disease to take account of their claims, their methods and their demonstrable accomplishments and, perhaps in the process, to develop a change in their point of view and acquire a new sense of proportion and perspective in pushing their present advantage against tuberculosis In the last fifty years there has been a fall of 77 9 per cent in the tuberculosis death rate in New York City, in the last eleven years, a fall of 51 per cent, and in the calendar year of 1921, a fall of 18 1 per cent

Of all the factors involved in this beneficent change, Haven Emerson [1] seems inclined to lay most stress on the improved financial and living conditions of the poor, including, with this, decreased alcoholism and the lessened expenditure for alcohol He says that it is probably not too much to say that in the next twenty-five years as great a percentage of reduction in tuberculosis can be attained as has been accomplished in the last fifty years, by adding to our methods and resources those which will build up bodily resistance by providing for and following a higher standard of living, and those which will diminish the hazards of occupation and of occupancy

The influenza epidemic, paradoxical as this may seem, has had undoubtedly a considerable influence in reducing recent tuberculosis mortality as shown by vital statistics, since deaths occurred because of influenza, which masked or at least permitted a preexisting pulmonary tuberculosis to go undiscovered, with the result that many who would have died of pulmonary tuberculosis within the last four years, and would have been reported as dying from tuberculosis, died of influenza without record of the simultaneous tuberculous involvement

A factor of much significance in the vital statistics of large cities, and especially in New York, is the racial change in our population due to unrestricted immigration of the Jewish people, especially from Germany, Russia and Poland up to 1914, and the limitation of all immigration since that date and more particularly since 1917 The Jews have notoriously a much lower tuberculosis death rate than most other people, especially the Irish, Scandinavians and Italians, whom they have largely replaced among the immigrants of recent years

Another factor not emphasized by Emerson, but which some other epidemiologists might stress, is the

1 Emerson Haven Am Rev Tuberc 6 282 (June) 1922

fact that our growing concentration of population has led to more universal exposure of the young to tuberculosis under favorable conditions for resistance, whereby they acquire a greater or less degree of immunity to subsequent fatal reinfection Furthermore, we cannot disregard the possibility, even though it has not yet been firmly established as a fact, that the survival of several generations exposed to tuberculosis confers at least some increased capacity to overcome the disease To what else can we attribute the racial resistance of the Jews to tuberculosis after generations of life in crowded, unhygienic conditions?

It will be noted that these favorable factors were not developed with the object of reducing tuberculosis, but rather they are merely social and economic events of a character to cause a reduction of the disease, which always reflects in its prevalence the great movements of races, changes in wealth and in industry, and pandemics of other diseases Hence it becomes extremely difficult to estimate the influence that has been exerted in pushing down the tuberculosis death rate by the purposeful efforts that have been made so vigorously in this country It would be of the greatest importance to know just what the effect has been of notification, segregation, hospitalization, and the host of sanitary measures and educational campaigns that have been introduced, but their influence on the falling mortality curve cannot be picked out and measured specifically Emerson holds that it is possible to see the effect of improving milk supplies by pasteurization, for since this has been enforced in New York, there has been a notable change in the rate of reduction of the nonpulmonary forms of tuberculosis in this city In 1914 the rate was 27, in 1921 it was 14 per hundred thousand That much of the lymphatic, bone and joint tuberculosis has been of bovine origin is admitted, and as a specific instance of the change since the general pasteurization of 98 per cent of all our city milk supply, instead of finding 64 per cent of a series of 100 cases of tuberculous adenitis to be of bovine origin, as was the case in 1912-1913, only 16 per cent of a series from the same hospital source were found to be of bovine origin in 1917 by Dr W H Park Whether or not adult pulmonary tuberculosis has been affected by reduction of the tubercle bacillus content of milk, the reduction of milk-borne bovine lymphatic tuberculosis of children is an accomplishment of great and lasting importance

In the absence of any possible way of estimating the value of each of the many other factors that have so wonderfully reduced the menace of tuberculosis, we can scarcely discard any of them that may reasonably be considered to play a part in the total result Medical, sociological and industrial betterments must continue their parallel progress in the future, since together they have accomplished one of the most remarkable advances yet made in human welfare

THE TRUE STATUS OF ENDOCRINOLOGY

The symposium on so-called internal secretions, and the various facts, problems and hypotheses often discussed under the name of endocrinology, at the St Louis session of the American Medical Association,[1] cannot fail to have a wholesome, stabilizing influence on the medical profession It is high time that physicians, to quote one of the authors, should have their feet on the ground when they attempt to enter domains where so few paths have been cleared, and where the directions for advancing to undiscovered goals are so largely the figments of unrestrained imagination Professor Carlson of Chicago, in particular, has attempted with commendable frankness and fervor to dissociate fact from fiction in the entangled claims about the ductless glands He deserves serious attention when he says that we cannot practice quack methods and escape the just censure of society This dictum is correct if, as Carlson firmly believes, much of the glandular therapy of today, however harmless to the patient, injures the good name of the medical profession with intelligent laymen

It is beyond the scope of these editorial columns to review the varied claims that have been made for the roles of the "principal endocrine organs"—the thyroid, the parathyroids, the thymus, the lymph glands, the suprarenal glands, the gonads, the pituitary, the pineal, the insular tissue of the pancreas (islands of Langerhans), with the added possibility conjectured by Barker [1] that other organs, as the spleen, the kidneys, the liver, the salivary glands and the prostate, also perform endocrine functions in addition to their other physiologic activities The outstanding facts are that extirpation experiments on healthy animals have shown the loss of a few of these organs or tissues to be followed by unmistakable symptoms of abnormality Disease may bring about similar lack of function in the case of some of the structures referred to, and it is highly probable that corresponding glandular hypofunctions in man will induce similar disease syndromes Latterly there has been a marked tendency to conceive of function in the case of the ductless glands on the basis of hormone production, that is, specific substances are produced by the structures under consideration, and, being carried to remote cells through the circulatory mechanisms, influence these parts as excitants or depressants, promoting or retarding their usual performance It is still possible, however, to interpret the symptoms produced by the extirpation of the ductless glands on the detoxication theory which formerly was foremost in the discussions in this field Thus, the products of the endocrine structures are supposed to perform the task of neutralizing

1 Barker L F Endocrinology J A M A 79 89 (July 8) 1922 Cannon W B Some Conditions Controlling Internal Secretion p 92 Aub J C The Relation of the Internal Secretions to Metabolism p 95 Carlson A J Hypofunction and Hyperfunction of the Ductless Glands p 98 Hoskins R G Some Principles of Endocrinology Applicable to Organotherapy p 104

poison and substances of endogenous or intestinal origin circulating in the body It is by no means easy to distinguish between the effect of a detoxicant and that of a "regulator"

The hormone theory of internal secretion has received a great impetus from the discovery that the extracts of certain tissues, and subsequently that chemical substances identified in them, exert pronounced physiologic effects on the organism The action of epinephrin and thyroxin are the classic illustrations It was a natural conjecture, though by no means a logical deduction, that the potent suprarenal constituent is in truth a secretory product which is discharged from the glands into the blood stream in order to accomplish in the physiologic economy in every-day life what the laboratory investigator has demonstrated that the isolated product can do The evidence, however, is far from substantiating this At any rate, the hypothesis that blood pressure is ordinarily sustained by suprarenal secretion and that disturbances of the latter condition pathologic variations in arterial tension is being abandoned At most it is asserted, though even this is debated vigorously, that the suprarenal output of epinephrin represents an acute emergency response in times of physiologic stress This is far from saying that epinephrin is an indispensable hormone and that the essence of suprarenal function lies in secreting it It has been demonstrated that an amount of epinephrin required to cause a rise of blood pressure is sufficient to stop all motions of the stomach and intestines[2] "A ridiculous mechanism it would be," says Cannon,[1] "that would stop digestion in order to provide a few extra millimeters of arterial tension! There is no satisfactory evidence that in natural, quiet existence, the suprarenal medulla gives off any secretion whatever"

It is a fundament of much of the current endocrine theory that the hormones produced, the internal secretions, the "incretions," as they have lately been designated, may act on distant cells in a modifying way, either directly through transport in the blood to them, or indirectly through intermediation of the nervous system Yet it is well to remember that no chemical methods are at present available by which we can demonstrate the presence of admitted hormones and their quantitative variations in the blood and tissues, or even in the glands themselves Epinephrin can be estimated, but who will say that it is a true internal secretory hormone? Iodin can be determined in the blood and thyroid, but is this element an index of all that the thyroid is assumed to accomplish, and is all iodin present as thyroxin? Little wonder, then, that we have been admonished that "no single phase of endocrine dysfunction is satisfactorily worked out today, either clinically or experimentally" It affords little help to hear that endocrinology has "arrived" Progress in endocrinology can at best come only slowly, and, to quote Rowntree,[3] through correlated, adequately controlled investigations in which the findings are subjected to interpretations based on analytic and critical judgment Endocrinology needs a leadership willing to admit the magnitude of its shortcomings Its real contributions will then become more evident

SMALLPOX

Like a volcano which rumbles and smokes long before it explodes, smallpox gives the world a timely warning Within the last five years, local epidemics have occurred in Scotland, Germany, France, Spain, Australia, Burmah, the Philippines, Mexico, Brazil, Argentina, Chile, Costa Rica, Santo Domingo, Canada, and in several of our own states, in one of which an epidemic exists at present There is evidence in these outbreaks to indicate that smallpox is becoming more virulent as well as more common The mortality rate in some instances has been as high as 40 per cent The number of cases in 1921 in ninety-three American cities was reported by the Metropolitan Life Insurance Company to be 138 per cent greater than in 1920, and the number of deaths in proportion to the number of cases, six times greater A contagious disease so virulent cannot be taken lightly, however restricted the area in which it prevails

The history of the disease in the prevaccination epoch shows that long periods of quiescence are followed by virulent epidemics The intervals are characterized by less virulent, sporadic cases, or by a mild type of the disease, such as has prevailed in the United States for about twenty years Susceptible material gradually accumulates during these years, chiefly from the large number of children that grow up unvaccinated By processes as yet not well understood, the virulence of the disease increases again, outbreaks become epidemics and smallpox once more stalks abroad as "Captain of the Men of Death" In the eighteenth century, only one person in twenty-five in England escaped the disease It was constantly present in London, where the deaths at times numbered from 3,000 to 15,000 yearly In the same century, Boston had seven severe epidemics With a population in 1721 of 11,000, Boston had more than 6,000 cases of smallpox and 850 deaths, a mortality rate of 77 per thousand To understand what that rate means, one should compare the epidemic of influenza of 1918, which caused only 8 deaths per thousand, about an eighth or a ninth of Boston's mortality rate from smallpox in 1721 In recent years, few large cities have suffered more than Philadelphia where, within the thirty-three years ending in 1904, three epidemics occurred, with more than 30,000 cases and 7,600 deaths In this day of rapid intercommunication, it is well to recall that smallpox was intro-

duced into Montreal in 1885 by an unvaccinated Pullman car porter, causing 15,000 cases and 3,164 deaths

Indifference to the disease and prejudice against the chief means of prevention make the present situation more serious A long period of comparative immunity has made people careless regarding vaccination, and some physicians have become careless and have failed to urge vaccination on their patients To make matters worse, a vicious propaganda has misled many people to oppose vaccination openly Thus the percentage of the population that is unprotected has grown and unless conditions in this regard improve, outbreaks of smallpox may be expected To encourage vaccination at this particular time is to do a public service

IS GERMAN DOMINATION OF DRUGS AGAIN IMMINENT?

Previous to 1914, the large proportion of the synthetic chemicals and drugs employed by American chemists and physicians was supplied by German chemical interests So slight, indeed, had been the sporadic attempts to create an American organic chemical industry that it was not even necessary for German importers to carry large stocks of necessary drugs Shortly after the outbreak of the war, serious shortages occurred, and the prices of imported drugs in America rose precipitously Arsphenamin—then known only under the proprietary name "salvarsan"—sold at fabulous prices, and many were deprived of this spirocheticidal agent So commercially important was the drug that it composed a large portion of the cargo of the *Deutschland* on its historic voyage During the period of necessity, THE JOURNAL repeatedly urged editorially that the patents on this drug be abrogated Concomitantly a shortage of dyes—interdependents of drugs—had occurred

In 1917, after war between the United States and Germany had been declared, Congress passed the "Trading-with-the-Enemy Act," which provided that German-owned patents could be operated by American citizens on the granting of a license from the Federal Trade Commission The nonproprietary names "arsphenamin" (for salvarsan), "barbital" (for veronal), "cinchophen" (for atophan) and "procain" (for novocain) were coined, and a number of American firms were licensed and began to supply the drugs under these names This was not accomplished, however, without considerable research work, because German patentees had, in many instances, violated the spirit of our patent laws, the very basis of the American patent system—nonsecrecy—had been circumvented Although both process and product letters of patent had been issued to foreign subjects, nevertheless frequently the patents were not workable, and the descriptions were inadequate for successful manufacture The Germans apparently took out American patents with a view to stifling any prospective American chemical industry

Shortly after the Federal Trade Commission began to grant licenses, the Alien Property Custodian (who had seized many patents along with other German property) was authorized to dispose of seized property, the proceeds from the sales to be held by the government until settlement was made with the enemy So it was that at first certain firms formerly under German control, such as the Bayer Company, were sold, together with the patents in which the firm's ownership was proved It was soon evident, however, that the establishment of a permanent chemical industry —so necessary for public health and national defense— could not be obtained in this manner A corporation, the Chemical Foundation, Inc, was then organized, to which the remaining 4,700 German patents were sold, by executive order, for the nominal sum of $250,000 The purpose of the foundation was stated to be the holding of patents, as a trustee, for the American chemical industry, "for the Americanization of such institutions as may be affected thereby, for the exclusion or elimination of alien interests hostile or detrimental to said industries, and for the advancement of chemical and allied science and industry in America" Licenses have been granted to any firm that could present satisfactory evidence of its reliability in chemical manufacture, no firm may have a monopoly on any patent As has been stated, all moneys earned are to be spent for altruistic purposes The Chemical Foundation has served as a bulwark in establishing chemical independence in the United States Today no shortage of drugs exists, while the quality of American-made synthetics is second to none The American chemist deserves credit for accomplishing this in spite of the many handicaps, such as the lack of facilities and the hindrances caused by the nonworkable patents Of course, drug manufacture cannot be successful without dye manufacture at the same time But the drug industry has been maintained in the days since the war in large measure through the efforts of the Chemical Foundation, which has kept the patents strictly in American hands, and has worked for the protection of the industry Other aid has been the embargo on foreign dyes

Now, however, a grave situation impends The embargo on dyes—without which an independent pharmaceutical industry is impossible—is about to expire, the Senate, by a close vote, has refused to extend time, and the tariff is unsettled President Harding, on the advice of the Department of Justice, has instructed the Alien Property Custodian to take steps to secure the return to the custodian of all patents sold, under the "Trading-with-the Enemy Act," to the Chemical Foundation, Inc, and has informed the custodian that, in carrying out the instructions he shall act

only on the advice of the attorney-general What is the significance of this action?

Considerable agitation has been noticed in Congress for the return of property of private owners among the peoples recently at war with the United States Such a bill is now before the House There is some soundness in the argument of the inviolate rights of personal property, but more emphasis should be given to the statement of the *Oil, Paint and Drug Reporter,* in this connection, that the "question of generosity toward unrepentant, pledge evading enemies shrinks into insignificance in comparison with the companion proposal that would nullify the industrial victory which apparently has been America's sole gain from the defeat of her adversaries" Another argument is that the patents were sold to the foundation at too nominal a price No fault can be found with the demand of the President for an investigation, if he has evidence that indicates that the public trust was violated in selling the patents at too low a figure Certainly, a clean-cut investigation should be most welcome particularly to the adherents of the foundation, although the method of attack seems unfortunate On the other hand, Mr Francis Garvan, president of the Chemical Foundation, insinuates that a group of lawyers from Germany, representative of the German dye and drug "cartel," together with representatives of German importers, visited the Department of Justice shortly before the attack was made on the foundation, and submits evidence which indicates that strong German influences are at work in this politicocommercial intrigue

The physicians of the United States must never again be dependent on a foreign country for essential drugs, the attendant evils of the past inadequacy are still fresh in our minds The organic chemical industry of America must be maintained in the interest of public health and national security Whether by the Chemical Foundation or by some other method, American chemical industry must be encouraged The American people should know what is really behind the recent agitation, which is apparently so favorable to the German chemical trust Germany was successful in creating a chemical monopoly not only because labor was cheap but, more important, because the German government subsidized and protected the industry America can be independent only if its chemical industry enjoys reasonable protection Never again should we face the dilemma of 1915 and 1916, never should we permit any foreign domination of our therapeutics

Mental Hygiene in Industry—The movement for a mental hygiene of industry is an endeavor to apply the mental sciences, psychology and psychiatry, in personnel administration for the purpose of developing the personality of each individual worker in the interests both of good work and of human happiness It is an effort toward what might be called scientific large-scale production of individualization—M C Jarrett, *Hospital Social Service* **36** 365 (May) 1921

Current Comment

THE METABOLISM OF PREMATURITY

The metabolism of the new-born has been the subject of extensive investigations in several laboratories of this country The outcome has been consonant with the now well established idea that the energy exchange of the young adolescent is decidedly larger than that of the age after puberty An adult may have a basal metabolism of approximately 1 calory per kilogram of body weight for each hour In children below 1 year of age, the figure may reach two and one-half times this Murlin and Hoobler[1] state that 60 calories per kilogram each day may be called the heat production of normal, recently fed infants at complete rest Newborn babies, however, have been found to have a metabolism less than this and not exceeding 48 calories per kilogram each day Whether the figures for the different ages of early infancy are not essentially alike when the comparisons are made on the much debated basis of body surface rather than body weight need not be discussed here It is of interest, however, to learn from studies by Talbot, Sisson Moriarty and Dalrymple[2] at Boston that the basal metabolism of prematurely born but organically sound babies is strikingly low from any point of view This fact is interpreted to be dependent on the circumstance that there is a small amount of active heat-forming tissue in such incompletely developed infants They have an unstable body temperature tending to subnormal, and are unable to compensate readily for loss of heat The relatively large food requirement under these conditions has long been recognized Rubner and Langstein[3] have found more than 40 per cent of the calories ingested as food to be retained by prematurely born infants, thus attesting the enormous "growth impulse" which they possess

MEDICAL LICENSURE IN ILLINOIS

Following the licensure scandal in Illinois a year ago, at least two investigating bodies have recommended to Governor Small that Director W H H Miller be removed or suspended from office One was the special committee appointed by the governor himself to make an investigation Nevertheless, the governor has refused to heed the recommendations Although Director Miller was charged with trafficking in examination papers and physicians' and pharmacists' licenses, his attorneys are attempting to prove, not that Miller et al were not guilty of the acts indicated, but that they were violating no law and, therefore, that the acts did not constitute a crime! How will the licensing boards of other states regard these actions? Will they be willing to continue reciprocal relations with Illinois when the licenses granted are under such suspicion? Can any excuse be found for such bartering in certificates

ALABAMA

Malaria Experiment—The city of Florence has been selected by the government as the location for investigations on matters of health, especially the transmission of malaria. The Rockefeller International Health Board is also interested in the work. Surg. Lunsford D. Fricks, U. S. Public Health Service, is in charge. He will establish headquarters shortly. Mr. Bruce Mayne of the government health department in Memphis and Mr. Bedell of the International Health Board, Rockefeller Foundation, have been placed in immediate charge of the work by Dr. Fricks. Mr. Mayne will do the research work, while Mr. Bedell has been assigned to northern Alabama to assist and advise with the county health officers in reference to problems of drainage and mosquito control.

CALIFORNIA

Physician's License Restored—At a meeting of the Board of Medical Examiners, State of California, June 28-29, the license of Dr. Calvin Luther Case, Oakland, which was revoked, Jan. 9, 1917, was restored. This entitles Dr. Case to again practice as a physician and surgeon in the state of California.

Ophthalmologic Course—Professor Fuchs of Vienna recently accepted the invitation of a group of ophthalmologists in San Francisco to give a private course of lectures during his visit on the coast as the guest of the California Academy of Medicine. The course commenced, July 10, at the Stanford University Medical School. It will consist of thirty hours and will extend over three weeks.

Typhoid Campaign—The state board of health has started an active intensive campaign for the improvement of sanitary conditions of Japanese vegetable, berry and fruit farms. The Japanese association and the tenants of the farms showed a marked willingness to cooperate with the state board of health in this work. To date more than 100 old cesspools have been filled in and eighty new ones provided, the land owners supplying the material and the Japanese tenants performing the necessary labor to install the new equipment.

COLORADO

New Medical Society—The Tri-County Western Slope Medical Society was organized in Delta, June 22, consisting of the counties of Montrose, Delta and Grand Junction. This society was formed for the purpose of promoting social intercourse among medical practitioners of the three counties and for the education of and promulgation among the people of medical knowledge. Dr. Arthur William McArthur, Delta, was elected president of the society.

DISTRICT OF COLUMBIA

Typhoid at Church Supper—After a supper given by the Grace Lutheran Church in Washington, recently, forty-four guests were stricken with typhoid fever. According to Health Officer Fowler, most of the food was prepared the previous day and not kept on ice. Also two apparently healthy typhoid carriers aided in the preparation of the supper.

FLORIDA

New Medical Society—At a meeting of physicians at Sebring recently, the Highlands County Medical Society was organized, with Dr. Robert J. McMurray, Sebring, president, Dr. Joseph L. Cloud, Avon Park, vice president, and Dr. J. H. Bogle, Sebring, secretary-treasurer.

Personal—Dr. Ralph N. Greene, former state health officer, has been chosen president of St. Luke's Hospital, Jacksonville, to succeed G. H. Wall, superintendent of the institution who has resigned, the resignation to become effective, August 1.——Col. Raymond C. Turck, state health officer, has been awarded the distinguished service medal for services rendered during the Meuse-Argonne offensive in 1918.

Maternity Welfare Offices—The state offices under provisions of the Sheppard-Towner act have been established in the state board of health building at Jacksonville, under Dr. William B. Keating, director of the state child welfare bureau and were opened July 1. Approximately $16,000 will be spent on the work, it was stated, during the next year. The state will be divided into subdistricts, with a supervising nurse at the Jacksonville headquarters.

ILLINOIS

Physician Fined—It is reported that Dr. Edward A. Weisenhorn of Teutopolis recently paid a $40 fine and costs for failure to report births that had occurred in his practice. The court action against Dr. Weisenhorn was instigated by the local state's attorney at the request of a special agent of the state department of public health.

Baby Conferences Unusually Popular—The popularity of the better baby conference movement in Illinois is indicated by the heavy demands on the state department of public health for professional aid in organizing and directing local conferences at various points. Up to June 30, 1922, the department had furnished the personal services of an experienced physician and nurse to twenty-five different communities during the half year, while a schedule has been arranged for supplying similar services to thirty-four additional communities during the remainder of the summer and fall. Of the total of fifty-nine conferences, twenty-seven have been or will be held in connection with county fairs.

Consultation Service in Venereal Disease Cases—The division of social hygiene of the state department of public health is cooperating with the division of venereal diseases of the U. S. Public Health Service in carrying out a recently developed plan whereby the advice and counsel of several of the nation's most prominent syphilographers and genitourinary surgeons are made available to the practicing physicians without cost. The plan is referred to as the "consultation by correspondence" service. Private practitioners may forward descriptive information and other essential data relative to any of their patients, either to the state department of public health at Springfield or to the U. S. Public Health Service at Washington and this information will be placed promptly in the hands of the proper authority, for detailed and comprehensive discussion and reply.

Chicago

Social Insurance in Germany—The *Munchener medizinische Wochenschrift* warns that a small cloud is visible to the medical profession on the horizon in the recent demand of certain German housewives that the business of being a housewife should be recognized as a regular trade

Anniversary of van Swieten—Our Vienna exchanges mention that June 18 was the hundred and fiftieth anniversary of the death of Gerard van Swieten 1700-1772 He was a pupil of Boerhaave and was called from Leyden to Vienna by the Empress Maria Theresa He reorganized the entire system of medical education in Austria

A Discriminating Publication—The *Revista de Higiene y de Tuberculosis* of Valencia Spain is particular in choosing its exchanges It has published a list of papers, with which it refuses to exchange, because of their being devoted to the advertising of "patent medicines" The list follows *Le Monde Medical La Médicine Pratique, Revista de Tecnica Medica, La Medicina Internacional, Revista de Informacion Terapeutica, Clinique et Laboratoire, La Rassegna di Clinica Terapia, Boletin del Suero Cuguillere Revista de los Laboratorios Americanos* and *L'Avenir Médical*

Italian Congress of Radiology—At the fourth annual congress held in Bologna, May 9-11, under the presidency of Prof A Busi, the following officers were elected honorary president, Prof Senator O Corbino, president, Professor Bertolotti, Turin, vice president, Professor Balli, Modena, secretary-treasurer, Professor Ponzio, and chief editor of the journal of the society, Professor Perussia Milan Palermo was chosen as the place for the fifth congress to be held in October, 1923, under the presidency of Professor Scaduto Professors Ceresole, Alessandrini, Tandoia, Maraghiano, Rossi and Spagnolio were among those who read papers at the meeting

Personal—A bust of Dr E Lang, the founder of the Lupus Institute at Vienna was recently unveiled at the opening of the new carbon arc lamp hall——The Wiesbaden roentgenologist Prof Alban Kohler, has been elected an honorary member of the Spanish Society for Radiology and Electrology——Prof P Muhlens of Hamburg has been asked by the government of Jugoslavia to study and report on malaria in that country He has accepted an invitation to lecture in Barcelona in the fall on malaria, spirochetosis and affairs in Russia——The king of Spain has decorated with the Grand Cross del Merito Militar the following Belgian physicians, in token of appreciation of their services to the Spanish army training camps Dr Voncken, Dr De Block, Dr Wibin and Dr Vandermissen——At the recent annual meeting of the organized ophthalmologists of Germany, the Graefe prize was awarded to Behr of Kiel Hertel of Leipzig and Koppe of Halle——The *Ugeskrift for Læger* mentions that Prof M H E Tscherning of Copenhagen has been decorated by the government of Norway, and Drs Marner, Hempel-Jorgensen and I Hansen have been decorated by the Austrian Red Cross

Deaths in Other Countries

Dr **W Gauld**, formerly medical missionary at Swatow, China, died in London, June 14, aged 82——Dr **Archibald L McLean**, at the Royal Prince Alfred Hospital, Sydney, May 13 following a long illness——Dr **Alfred Sutton**, Surgeon, A M C, of Australia since 1900, was mentioned in dispatches four times during the late war and received several decorations, died recently at Brisbane, Australia——Dr **Jacques Bertillon**, aged 71, inventor of the finger print system of identification, which his brother adapted for practical use He had charge of the bureau of statistics at Paris, in which position his father and grandfather had preceded him——Dr **G Bayer**, director of the hospital at Hannover-Linden——Dr **G Meschieri** of Pollenza, Italian bacteriologist——The *Dermatologische Wochenschrift* mentions the death of Dr **E von Negri** of Amsterdam, known by her works on granuloma malignum, etc, and of Dr **W B Zogbaum** of Christiania, the inaugurator of the first institute in Norway for treatment with radiant energy

CORRECTION

Appointment as School Health Director in Utah—In THE JOURNAL, July 8, page 142, it was stated that Dr C C Jensen, Riverton, Utah, had been appointed as state director of health education The item should have said that C N Jensen, Ph D, state superintendent of public instruction at Salt Lake City, would hold this position

Government Services

Organization of New Reserve Units

The Surgeon-General of the Army announces the authorization of the following new units in the organized reserve General Hospital No 51 (Georgetown University School of Medicine), General Hospital No 52 (Syracuse University School of Medicine), Surgical Hospital No 15 (Italian Benevolent Institute and Hospital, New York), Evacuation Hospital No 20 (Flower Hospital Unit, New York), General Hospital No 54 (State University of Iowa College of Medicine), General Hospital No 6 (Massachusetts General Hospital Unit), General Hospital No 48 (Metropolian Hospital, Department of Public Welfare, New York), and General Hospital No 53 (St Louis University School of Medicine)

Vocational Training of Veterans

Figures just issued by the U S Veterans' Bureau show that a total of 601,515 veterans of the World War have applied for vocational training, of which number 312,930 applications have been approved In addition to the 30,000 factories and industrial organizations which are affording placement training to the 36,704 veterans, there are 3 228 institutions engaged in the work of remaking men who are disabled or partially disabled Of this number, there are 162 universities, 253 colleges, 98 state normal schools, 1,041 commercial schools, 244 public schools, and 266 institutions teaching miscellaneous subjects Of these, 49 are government institutions The number receiving instruction has almost doubled in the period from July, 1921, to May, 1922 July 1, 1921, there were 85 338 men actually taking vocational training, and on May 1, 1922, there were 108,919

Chicago U S Veterans' Bureau

The District Office at Chicago (No 8) has moved from the Leiter Building to the Butler Brothers Building The cooperation section of the administrative division occupies space on the tenth floor, approximating one half of a city block, while the district office occupies the entire eleventh floor The change was made in accordance with the general economic program now being practiced by the bureau It is estimated that between $100 000 and $150,000 a year will be saved in rental alone——Col C R Forbes, director of the U S Veterans' Bureau, made an inspection trip to District 8 recently He inspected the new offices and the new site for the $3,000 000 hospital for neuropsychiatric cases, to be established at Great Lakes He expressed himself well pleased with the morale and the conditions of the district, and addressed a communication to this effect to all of the employees of the district, thanking them for their service and cooperation

Hospital for Tuberculous Service Men

A 500-bed hospital, costing $1,500 000, for former service men suffering with tuberculosis will be erected at Tupper Lake, N Y, instead of the proposed 250-bed institution at Liberty, N Y, according to an announcement made by Acting Director Rogers of the U S Veterans' Bureau Mr Rogers also announced that the Veterans' Bureau is to turn over to the Treasury Department the sum of $750,000, to enable it to increase the capacity of the hospital to be erected at Chelsea, N Y, from 250 to 500 beds making the total cost of the Chelsea hospital $1,500,000 These projects when completed will give the New York district facilities for caring for 1,000 tuberculous patients Decision to abandon the proposed site at Liberty, N Y, it was explained by Director Rogers, was made on recommendation of the General Hospitalization Board It was found that the land there was unsuitable and the 150 acres at Tupper Lake, to be donated by the chamber of commerce of that town, was selected instead Survey of the land at Tupper Lake is already under way and bids for the construction of the new hospital will be called for shortly Assistant Secretary of the Treasury Clifford also announced that the Treasury Department had selected the Hall property at Aspinwall, Pittsburgh, as a site for a new veterans' hospital, to care for disabled ex-service men of the Pittsburgh district The institution will contain 250 beds and will cost approximately one million dollars

The Hall property consists of 145 acres overlooking the Allegheny River With the location of this hospital, the Treasury Department has completed its program for hospital construction under the act passed by Congress last year appropriating the sum of $18,600,000 Since then $35,000,000 has been appropriated by Congress the matter of its expenditure being placed in the hands of the U S Veterans' Bureau Assistant Secretary of the Treasury Clifford gave out information to the effect that the Perryville, Md, project, increasing the size of the veterans' hospital there by 300 additional beds had been completed The Bronx Hospital, New York, of 1,000 beds has been completed

The Prevention of Venereal Disease

The Society for the Prevention of Venereal Disease has made a step forward and promulgated a detailed policy It takes its stand on three main principles 1 It is the duty of every good citizen to live a chaste life 2 It is the office of medical science to prevent the consequences of sexual immorality According to the Royal Commission on Venereal Diseases, the number of persons affected with syphilis, acquired or congenital, cannot fall below 10 per cent of the whole population of the large cities, and the percentage of those affected with gonorrhea must greatly exceed this The tragic fact is that the evil passes to innocent women and children 3 Venereal disease can be prevented by immediate self-disinfection, provided it is intelligently applied Self-disinfection may fail by misuse or delay, but this is no argument against its efficacy The society also insists on the obligation of seeking and testing new measures of prevention It looks with favor on all curative measures, and heartily approves of venereal clinics It teaches that instruction in the methods of self-disinfection should not be refused to males who have reached adolescence, to adult women if they desire it, or even to younger persons at the discretion of their parents or those responsible for their welfare It advocates the propagation of such knowledge as may tend to diminish venereal disease and its grave consequences by lectures and leaflets, assuming that the lectures are attended and the leaflets received only by such persons as have reached adolescence

Following this preamble the society's policy is laid down under five headings 1 To instruct the public as to (*a*) the great importance of self-disinfection at the time of exposure and (*b*) the methods of doing this 2 To give such instruction only to men above the age of 18 to adult women on demand, and to younger persons in special cases at the discretion of those responsible for their welfare 3 To insure the sale of the disinfectants required with full instructions to such persons and to such persons only 4 To convey instructions regarding the nature and application of such disinfectants to such persons (1) by leaflets supplied (*a*) with disinfectants at the time of sale and (*b*) by attendants at public conveniences on demand (2) by lectures, (3) by medical officers of venereal clinics (4) by officers or officials in charge of naval, military and industrial units 5 To advocate such further steps for the prevention of venereal disease as may from time to time be deemed advisable by the executive committee

Medical Society for the Study of Venereal Diseases

A meeting has been held in London at which it was decided to form a medical society for the study of venereal diseases The chairman, Dr David Watson of Glasgow, stated that those engaged in venereal work had expressed a desire for a society in which these diseases would receive due consideration A constitution was adopted and it was agreed that, subject to the approval of the council, local divisions of the society may be formed The question of the publication of a journal was remitted to the council for consideration The officers elected to act until the first general annual meeting, to be held in July, were president, Dr David Watson, Glasgow vice presidents, Dr Wilfred Fox and Mr F S Kidd, London committee, Dr Mary Liston, Edinburgh, Mr D Vinrace Dr D Wyndham Powell and Col L W Harrison, London, secretary and treasurer, Mr E R T Clarkson, London

Protest Against a Medical Play

An English version of Baron Rothschild's play "Le Caducee' is to be produced in London It may be remembered that the principal character is a fashionable surgeon who is a scoundrel He performs unnecessary operations from which patients sometimes die, and he divides the fees with obscure physicians He invites newspaper representatives and photographers to his operations in order that they may advertise him The *British Medical Journal* has made a protest against the play It holds that "the whole atmosphere of the play is distasteful to any one to whom the honor of the medical profession has a meaning at all, besides being grossly untrue to life It has also been pointed out in the press by a physician that anything that tends to lower a patient's confidence in medical advice when an operation is necessary is to be deplored as the sick require all the moral support that can be obtained On the other hand, Dr Arthur Bourchier, who is producing the play and taking the role of the surgeon, declares that there are black sheep in every flock and that the play represents the black sheep as he works in Paris and no doubt, in London He fails to see why the public should not be warned against such villains As Baron Henri de Rothschild is a physician, he knows what he is writing about Mr Bourchier added that a special performance had been arranged in aid of the funds of Guy's Hospital

Protection of the Race Against Multiplication of Mentally Defective

Mental deficiency is hereditary and those who suffer from it are prolific more prolific than the general public, as the moral and economic restraints which diminish fecundity do not come into play Their multiplication is not only a burden to the community but tends to deteriorate the race In a series of articles, this evil has been discussed in the *Morning Post*, and the suggestion of Sir Archdall Reid, that all mental defectives should be sterilized and thus rendered incapable of propagation is recommended A correspondence in which many well known persons joined shows that public opinion in this country is not ripe for such a remedy In the United States legislation has gone to the extent of permitting compulsory sterilization but it is not employed The patient is consulted or if his mental powers do not allow this the question is submitted to his relatives

Dr A F Tredgold a well-known expert on mental deficiency points out that segregation is just as efficient as sterilization and has other advantages All mental defectives are incapable of maintaining existence and at the same time conforming to the laws of the community without some amount of control, either for their own protection or the protection of others Many spread venereal disease and many commit crimes Hence a considerable proportion should be detained in institutions even if they are sterilized Dr Tredgold states that there are thousands of defectives in this country who either for their own sakes or for that of the public should be in institutions and the failure to provide

accommodation on the ground of economy is an extremely short-sighted policy He does not consider it possible to apply sterilization to all grades of mental defectives without risk of including nondefectives In the case of idiots and imbeciles, diagnosis is easy, and such risk does not exist But these classes comprise less than one fourth of the total number of defectives Many of them are naturally sterile and therefore do not need the operation The great danger of propagation arises in the class of the feebleminded, to which fully three quarters of all defectives belong and which is highly prolific

Diagnosis in these cases may be very difficult During the unstable period of adolescence, there are many varieties of mental abnormality, readily confused with defect, which are often temporary and amenable to treatment There is, moreover, a very large class, known as "border-landers," who occupy a position between defectives and normal persons While considering sterilization justifiable and advisable in particular cases of defect, Dr Tredgold points out that it does not remove the necessity for segregation and institutional care in a large proportion of cases

Cancer in France

More than half of Volume 5 of the new Traite de Medecine, recently published under the supervision of Profs G H Roger, F Widal and P J Teissier by Masson et Cie, is devoted to the study of cancer The authors, G Roussy, associate professor of the faculty of medicine of Paris, and Maurice Wolf former head of the department of pathologic anatomy of the faculty of medicine of Strasbourg, discuss our present knowledge of cancer from various standpoints biologic, anatomicopathologic, clinical, experimental and therapeutic To this Roussy and Wolf have added an interesting chapter on cancer viewed from a social standpoint, including statistics and information concerning the campaign against cancer as it is organized in various countries It is interesting to note what has been done in France along these lines

CANCER STATISTICS IN FRANCE

Roussy and Wolf begin by stating that the French are not fond of statistics, and that few statistics are published in France as compared with America, England and Germany, where statistical researches occupy an important place in medical science Whatever may be their value, the official statistics furnished by the ministry of the interior concerning mortality due to cancer in France from 1906 to 1916 are here presented

NUMBER AND PROPORTION OF INHABITANTS DYING FROM CANCER

	Total Number of Deaths			Proportion per Thousand Inhabitants		
	Communes			Communes		
Year	Cities of 5 000 or More	of Less than 5 000	Total for All France	Cities of 5 000 or More	of Less Than 5 000	Total for All France
1906	14 339	12 967	27 306	1 00	0 52	0 70
1907	14 381	14 900	29 284	0 99	0 60	0 75
1908	14 757	15 367	30 124	1 01	0 62	0 76
1909	14 907	15 738	30 645	1 01	0 63	0 77
1910	15 256	16 047	31 303	1 02	0 65	0 79
1911	15 897	15 871	31 768	1 04	0 65	0 80
1912	15 979	15 894	31 873	1 05	0 65	0 80
1913	16 429	16 405	32 834	1 08	0 67	0 83
1914	14 202	12 274	26 476			
1915	13 971	10 596	24 367			
1916	14 407	10 920	25 327			

Large cities have, as a rule, a greater cancer mortality than small cities Thus, in 1913, the proportion of deaths due to cancer per thousand inhabitants was cities of from 100,001 to 551,000, 1 20, 30,001 to 100,000, 1 17, 20,001 to 30,000 1 07, 10,001 to 20 000, 1 05, and 5,000 to 10,000, 0 79 The percentages of deaths from all causes due to cancer in France were 1906, 3 51, 1907, 3 69, 1908, 4 05, 1909, 4 06, 1910, 4 41, 1911, 4 10, 1912, 4 60, 1913, 4 67, 1914, 3 82, 1915, 3 85, and 1916, 4 27

Present Status of the Campaign Against Cancer

With the beginning of the twentieth century, the campaign against cancer received a new impulse, which became manifest in France, England and the United States at approximately the same time Dr Roussy, who was entrusted with a scientific mission to America (THE JOURNAL, Jan 7?, 1921, p 257) lauds 'the spirit of organization and method prevailing in the United States" which has made possible the creation, in New York, Chicago, Boston, Buffalo, St Louis and other cities of many hospitals, institutes and laboratories admirably organized for the study of cancer "In France,' Roussy and Wolf state, "we must frankly admit that we have been left far behind" It is only during the last few years that the movement in favor of the campaign against cancer began to materialize The department of public welfare of Paris opened cancer services at the Brevannes and the Salpetriere hospitals, but these services lack resources and equipment The general council of the department of the Seine made the necessary appropriation in 1921 for the creation of a service for the treatment of cancer in the Paul-Brousse Hospital at Villejuif This service was placed under the direction of Dr Roussy, and opened in October, 1921 The municipal council of Paris showed its interest in the movement by purchasing 2 gm of radium and by instructing the department of public welfare to organize in its hospitals centers for the treatment of tumors with radium and roentgen rays Two of these services are in operation at present at the Hotel-Dieu and at the Tenon Hospital The Radium Institute of the University of Paris, annexed to the Sorbonne, comprises a physical laboratory in charge of Madame Curie, and a biologic laboratory in charge of Regaud This laboratory comprises a department of physics (roentgen rays and radium), a department of pathologic anatomy (histology, biopsy), and an experimental and therapeutic department (roentgen rays and radium) The Radium Institute has also a collection of anatomic specimens and a library To the institute is annexed a patients' service in the Pasteur Hospital with consultation for outpatients We must also mention two associations for the study of cancer One, the Association française pour l'etude du cancer, founded in 1908 by Prof Pierre Delbet is above all, a scientific society publishing a monthly bulletin in which appear works pertaining to cancer The other association was founded during the war by Professor Hartmann, and is called the Ligue franco-americaine contre le cancer It deals especially with the sociological aspects of the campaign again cancer I have mentioned in previous letters various forms of its activity

Table Utensils and Contagious Diseases

Table utensils play an important role in the diffusion of contagious diseases, and I recently mentioned the poor conditions under which washing of glassware is done in restaurants (THE JOURNAL, March 4, 1922, p 666) Drs Dejust, Wibaux and L Dardel recently presented an interesting communication concerning pathogenic bacteria on table utensils and the best methods of disinfection They studied the conditions under which a glass article can be rid of bacteria by the use of running water, by running water plus rubbing or by the use of a soap solution, these methods being followed or not by drying with a cloth This research disclosed the slight efficacy of washing with water even when it is accom-

pumed by rubbing Of thirty articles of glassware soiled by cultures of *Bacillus prodigiosus* and washed with water without being wiped, twenty-two were still infected with the bacilli On the other hand, of twenty-four such articles washed in the same way but wiped, only five remained infected Of six articles washed with a 2 per cent soap solution without being wiped, five presented the bacilli, while of twenty-two articles washed with a 2 per cent soap solution, followed by wiping, none showed *B prodigiosus* The influence of drying with a cloth is obvious, especially when it follows washing with soap

The Physical Reeducation Centers

The army recruiting bill contains an innovation which is being sharply criticized Criticism is directed against the "reeducation centers" established for young men who are neither accepted for service nor exempted but are referred to another examination later The postponement is based on their lack of physical development owing to defective living conditions, or unhygienic surroundings, or the fact that their physical condition, while temporarily below par, owing to a recent illness, appears susceptible of rapid improvement The committee on hygiene of the chamber of deputies considers this innovation open to criticism Monsieur Justin Godart, chairman of the committee and former undersecretary of state of the sanitary service, stated that these reeducation centers are to receive convalescents and weakly young men who have been brought up in a poor environment But how, in practice, can we distinguish between these two classes of young men? If their condition must be the result of "defective living conditions or unhygienic surroundings," inquiry must be made concerning their home environment and their surroundings at work As regards convalescents, it would probably be preferable to let them remain at home instead of transplanting them, while at their lowest point of resistance, to a collective mode of existence, which always entails a critical period of adaptation and presents dangers of contamination Thus, the committee on hygiene of the chamber of deputies opposed the creation of these reeducation centers as dangerous and likely to entail unnecessary expense since their purpose would be to complete regimental ranks rather than to fill an urgent need Dr Sabatier, medical inspector in chief, with the rank of brigadier general, is also of the opinion that the army is not qualified to undertake to give to underdeveloped young men as a class the physical development required to make them fit As there would be many young men of delicate constitution to deal with, it is to be feared that the reeducation centers would not accomplish their purpose and would unless carefully supervised, entail the care of many patients, and many pensions and deaths

Proprietaries and the Academy of Medicine

I mentioned recently the protest of the *Journal des Praticiens* based on the fact that certain communications presented to the Academy of Medicine, while seemingly of a scientific character, in reality served as an advertisement for new pharmaceutic specialties (THE JOURNAL June 3 1922 p 1735) A recent occurrence supports their contention The *Bulletin de l'Academie de Médecine* of March 28 contains a communication by Dr E Doumer professor in the medical department of the University of Lille, concerning the good results secured from the use of paper compresses impregnated with a mixture of a certain acid and paraffin in the treatment of rheumatism and gout Immediately Paris physicians received a reprint of the article contained in the *Bulletin* together with a circular giving the address of the manufacturer of the compresses, the price per package etc The *Journal des Praticiens* remarks in an editorial 'It is impossible to imagine a more shameless use for commercial purposes of a supposedly scientific communication, and a more flagrant attempt to derive a commercial advantage from the prestige of the Academy of Medicine" The *Journal des Praticiens* requests a modification of the academy's rules, so that a communication concerning a new remedy must first be submitted to a committee, which would take all necessary precautions to inquire into the subject If presentation of the communication is authorized, the author would be requested not to abuse the authority "and thus transform the Academy of Medicine into a sort of broker's office to help the sale of a pharmaceutic specialty"

Award of Hanbury Gold Medal to Professor Perrot

The Hanbury gold medal has been awarded to Prof Emile Perrot professor of the faculty of pharmacy of Paris, for his works on medicinal plants and materia medica in general This medal commemorates the works of the famous English naturalist and is awarded every two years to promote and reward original researches in the chemistry and natural history of drugs

New Genito-Urinary Journal

The first number of a new medical journal entitled *Archives des Maladies des Reins et des Organes Genito-Urinaires* has just been published This publication is under the direction of Prof L Ambard of Strasbourg and Dr E Papin of Paris, and will appear in volumes of 128 pages, six times a year (G Doin publisher, 8 Place de l'Odeon, Paris) The first number contains a study by Papin and Ambard on the innervation of the kidneys, an article by Pasteau on the treatment of traumatic stricture of the ureter, another by Verhac on the value of laboratory research applied to diagnosis of tuberculosis of the kidney, and an essay by Ambard and Lux on diabetes insipidus The first number is devoted to original articles, but the publishers intend to put the reader in touch in the following numbers, with all the works concerning the kidneys and genito-urinary organs, and to give an extensive bibliography, as well as general reviews and clinical, therapeutic and technical laboratory data of interest to urologists

Tribute to Cajal

Prof Ramon y Cajal of Madrid has been granted an honorary degree by the council of Bordeaux University

VIENNA

June 23, 1922

Convention of the German Gynecologic Society at Innsbruck

The third Austrian university town, Innsbruck was selected by the German Gynecologic Society as a meeting place for its yearly convention at this time Owing to the pressure of time—it lasted only three days, June 8-11—and to the hardships of travel in central Europe little attention was paid to purely social activities, more earnest work being the aim Surgeons from northern Europe, Switzerland, Japan, Jugoslavia and America were present More than 208 papers were presented, exceeding the number read at any previous meeting of the society The young men were in the majority at the convention because the older men were unfitted for the hardships attending the journey and the overcrowded conditions of the city Thus, their ripe opinion had to be foregone. The papers were divided under four heads treatment of cancer by actinic methods (radium or roentgen rays) the mechanism of labor internal secretion and the treatment of infection following abortion At the convention in Halle nine years ago radiotherapy seemed to promise a new era in the problem of cancer of the genital organs, but at this year's meeting the high expectations met with disappointment Professor Bumm of Berlin pointed out that

the results obtained by a number of competent observers have shown clearly that, in selected cases, a permanent cure can be obtained by means of radiotherapy alone or in combination with surgery, but it is far from being a cure for more than a modest percentage of cases An interesting addition to the instrumentarium of the radiologist is an invention by three Innsbruck physicians, demonstrated at the congress, which employs the spectroscope of the roentgen rays to measure their intensity Thus, a simple and effective control of the dosage is obtained In the second group of papers, Dr Warnekros of Berlin challenged the teaching of Sellheim of Halle He had studied the different phases of labor, as well as the conditions during the last weeks of pregnancy, by roentgenograms, and he attributed a liberal share of the work necessary for the expulsion of the fetus to energy stored in the joints and ligaments of the pelvis However, the majority of those present favored Sellheim's theory

The problem of internal secretions was discussed in a number of papers, Halban, Aschner, Fellner and Hofmann contributing to the discussion No new point of view was brought out The correlation between ovary and thyroid, ovary and pituitary gland, and the corpus luteum and the uterine mucous membranes formed the subject of some interesting papers by clinical assistants At present, the situation is best termed as being still "in statu nascendi," in spite of the amount of knowledge accumulated within the last ten years Much time was taken up by the discussion of the treatment of puerperal sepsis (infection following abortion) and the justification of interruption of pregnancy Early surgical interference together with vaccine treatment was urgently recommended, while a number of men, including Dr Menge of Heidelberg and Dr Kupferberg of Mayence, were strongly opposed to the lenient or, as it was termed, unlawful attitude of the practitioner toward destruction of fetal life It may, however, be added here that at present there is an inclination among the legislators of Central Europe to make the interruption of pregnancy a legitimate procedure in many more or less suitable cases

Besides these four groups of papers, several interesting papers were read, among them one by Novak of Vienna on parthenogenetic generation in rats, by Werner on tuberculosis of the female organs and by Graff on the use of oxygen to inflate the tubes and control their permeability Thaler has succeeded in establishing regular periods in several cases of amenorrhea, with the aid of a weak (irritative) dose of roentgen rays Zacherl's (Graz) results in treating myomatous growths with radium are very encouraging Marked interest was evoked by the cinematographic methods of teaching used now in Vienna Professor Weibel presented his films, one showing the exact details of an operation for cancer of the uterus (Wertheim's operation) Another one showed the development of the human ovum and its fertilization, as demonstrated in the students' classes here Professor Frankl presented his models of human and animal embryos from the very earliest stages Dr Kogerer read a paper on posthypnotic painless childbirth, which caused quite a heated discussion The next convention is to meet at Heidelberg

Austrian Professors Lecturing Abroad

In the last year, several professors of Vienna University have been invited to lecture at foreign universities as a recognition of the high esteem of the standard of research in this city Dr Lorenz, who visited the United States, met more or less marked opposition Others, for example, Fuchs, have met only adherents Fuchs lectured in Spain and South America and is now in the United States Professor Haber lectured in Spain, on modern surgery, while Frankl, the gynecologic researcher, went to Dublin Professor Ruttin, the otologist, well known to many men studying in Vienna in the Allgemeines Krankenhaus, lectured in Holland and others are called to Roumania and Warsaw A series of exchanges has been arranged between German and Austrian universities and students also will profit by frequent exchanges Here the minor German universities chiefly are under consideration, and it is expected that such arrangements will bring about uniform methods of scientific instruction in these countries

The Relative Frequency of Progressive Paralysis in Vienna in the Last Twenty Years

Professor Pilcz, working in the statistical office of the ministry of health, and in the clinic for mental diseases of Vienna, has undertaken the task of ascertaining whether the condition known as progressive paralysis is increasing Several authors have answered this question in the affirmative, and it is rather difficult to weigh such statements simply by considering the case histories It must not be forgotten that the relative frequency of such cases in the hospitals for the insane depends on the kind and number of patients housed in such institutions altogether Thus, Kraepelin says that care must be exercised in giving the diagnosis, as well as the incidence, of syphilitic infections per se, before conclusions as to an increase or decrease can be reached Professor Pilcz has examined the records of the Vienna hospitals for the insane since 1902, and has computed the number of cases of progressive paralysis in proportion to the number of lunatics admitted, also to the entire population, and furthermore to those of the ages of from 30 to 50 years, and in respect to sex incidence He found that, while, in 1902, out of 794 770 males and 906,000 females living in Vienna 683 males and 510 females were admitted, among whom were 217 and sixty-seven, respectively, classed as suffering from progressive paralysis (273 and seventy-four, respectively, per 10 000 of the entire population), in 1912, the figures were 978,655 males and 1,093,000 females, with about 388 cases of males and 114 of females diagnosed as progressive paralysis admitted to the asylums, or 396 and 104 per 10,000 In 1921 the figures were 851,302 males 990 024 females, with 224 and eighty-seven cases, respectively, or 263 and 87 per 10,000 His investigations tend to show that, for about fifteen years, a constant, well marked drop in the relative incidence of these patients is noticeable, being most evident in the years 1920 and 1921 This subsidence appears even more marked in persons of from 30 to 50 Here the percentage of progressive paralysis among all insane patients dropped from 1,536 per 10 000 for males in 1910 to 789 in 1921, and from 359 to 260 for females The years of the war show a variation as the number of mentally defective is very high, and the number of those suffering from progressive paralysis is relatively low The conditions are nearly the same among the rural population as far as could be ascertained by the case histories, so that the working of the same factors may be assumed It appears that, in Vienna at least, a marked drop in the number of cases of general paralysis of the insane is evident The explanation cannot be sought in more efficient diagnosis, it is possible that the "genus morbi" has changed, just as the character of syphilis has changed within the last few years, and that fewer syphilitics fall victims to progressive paralysis for unknown reasons Thus, for instance, Mattauschek could show that out of 617 officers of the Austrian army treated for syphilis in the five years from 1884 to 1889, sixty or 7 72 per cent, developed progressive paralysis, but of 1,139 officers treated from 1894 to 1899, only thirty-seven, or 3 25 per cent, suffered in the same way Perhaps the low figures for 1920 and 1921 are the result of the malarial treatment of large parts of the populations instituted a short time ago, when many soldiers suffered from malaria and

syphilis in combination Professor Pilcz has renewed and continued investigations of these problems every ten years in order to clear up this riddle

BUENOS AIRES

(From Our Regular Correspondent)

May 21, 1922

Medical Congresses

The organizing committee of the Sixth Latin American Medical Congress, which will be held at Havana in November, has appointed the following Argentine committee Drs M Castex, E B Demarta, D Cabred, S Mazza, A Sacco, J Ingenieros, P Chutro, B A Houssay, D Cranwell, C Jacob, M Acuña, F Iribarne, H Caretti, A. Oyenard, J Llambias, C Bonorino Udaondo, M V Quiroza, G Bosch Arana, F Rosenbusch, J A Dominguez and J Arce

The Second National Medical Congress will be held in October The subject which will be discussed by all the sections is "Echinococcus Disease"

More Quarantine Stations

The national government has already equipped properly the two quarantine stations at Jujuy and La Rioja In addition, two disinfecting stations have been equipped at Chilecito and Olata Another quarantine station will be soon established at San Luis, a special building being constructed for this purpose

Importance of the Suprarenal Medulla

Drs Houssay and Lewis have kept alive fifteen dogs deprived of the whole left suprarenal medulla and the right suprarenal capsule These animals lived perfectly without showing asthenia, decreased tension or any other trouble, but as soon as the remaining suprarenal cortex was removed, the dogs died, in from twenty-two to twenty-six hours These experiments show that the existence of the cortex is necessary to life but the medulla does not fill any essential role In all cases, serial tissue examinations were made

Smallpox

The smallpox epidemic still persists in the province of Cordoba, where many of the inhabitants are opposing vaccination, which is precisely contrary to conditions on the coast The disease has appeared at Zapala and Minas (Neuquen), and near the Chilean border

New Hospitals

The new buildings for the Misericordia and San Juan de Dios hospitals, at La Plata, have been officially dedicated The Misericordia Hospital is connected with the Policlinico, where a radium institute for cancer has just been established The Policlinico Hospital is now cooperating with the La Plata Medical School

Medical Schools

At the Buenos Aires Medical School Dr Julio Iribarne was unanimously elected dean Dr Iribarne is a young assistant professor who has shown himself very active in reform movement in the last few years The new budget carries larger appropriations and it is intended to enlarge some courses, reduce the number of pupils (5 000) and increase the salaries of professors It is expected the proposed changes will benefit both teaching and research work

At Cordoba, the student strike has just been called off

Prof George F Nicolai, from Germany, who has been engaged to teach physiology, has just arrived Dr Nicolai, whose pacifist views gained him much publicity during the war, became known for his research work in physiology of the heart and electrocardiography, although of late he has been doing clinical work

At the Rosario Medical School, an attempted strike has just failed The students became incensed at the government for appointing directly the first directing board of the school and the dean

Tribute to Dr Lorentz

The societies of public health and biology have rendered a public tribute to the memory of the late Dr Emilio Lorentz Although his death was untimely, he had already distinguished himself as a competent and painstaking research worker Together with Dr I Aphatie, he discovered, after Ghedini and before Weinberg, the reaction of complement fixation for the diagnosis of echinococcus disease, besides carrying out several immunologic (Wassermann test) and bacteriologic investigations He was the director of the army laboratory

BERLIN

(From Our Regular Correspondent)

June 24, 1922

Retirement of Professor Rubner

Rubner the physiologist, of the University of Berlin, having completed his sixty-eighth year, will be retired from his position, October 1, under the old age pension act Rubner has been an instructor in the University of Berlin since 1891 The professorial chair that was created for and by Robert Koch was held by him only a few years One reason for this was that there were many fields of hygiene in which he took no particular interest, then, again, he did not find in the imparting of instruction the pleasure that some men do Consequently, Rubner—a pupil of Voit and Ludwig—who had already won a reputation by his excellent work in the field of physiology pertaining to nutrition, was appointed to take his place As a result of his previous training, the predominant factor and the main interest of Rubner's work lay in the domain of physiology Therefore, after the death of the physicist Engelmann, he was glad of the opportunity that thus arose of securing the chair of physiology in Berlin His transfer from one chair to another has another point of interest, since at the suggestion and under the direction of Rubner a new hygienic institute was built But when Rubner changed chairs, he also changed institutes, so that the old hygienic institute which had formerly, under du Bois-Reymond been established as the physiologic institute, was placed at the disposal of Flugge, who succeeded Rubner It will doubtless be remembered by some that when Rubner was called to succeed du Bois-Reymond, it caused some public excitement, not only on account of prospective buildings and equipment but also because of personal considerations Hermann Munk who at that time was professor of physiology at the Tierarztliche Hochschule in Berlin, was recognized as having a strong claim on the chair It is still uncertain who will become Rubner's successor The Halle physiologist Abderhalden would seem to deserve first consideration, and perhaps Hober, who occupies in Kiel the chair of physical medicine, may be in line

Scurvy in Germany

In addition to the cases of scurvy reported in a previous letter, a number of others have arisen Professor Umber director of the Charlottenburg Hospital, recently presented a number of patients at a meeting of the Berlin Medical Society He stated that not only had the subject of scurvy never been discussed before the Berlin Medical Society, as far as he knew since the sixties but that he himself, during his long practice extending over many decades had but recently seen the first scurvy patients (seven severe cases since the first of January) Others reported their observations on scurvy in Berlin and other large German cities All were agreed that the cases were due to lack of fresh vegetables and the consequent deficiency in vitamins in the diet

Umber stated that he had brought about a rapid recovery of the patients by prescribing a decoction of pine needles This remedy was first proposed by a Swedish military surgeon, who applied it during the expedition of Charles XII to Russia The needles are pounded with a pestle, and a "tea" is made from them

State Institute for the Study of Efficiency Engineering and Industrial Hygiene

A recognition of the importance of industrial psychology, which, owing to the influence of propaganda from America, is coming to the front here more and more, is the underlying factor that has induced the head committee of the Prussian legislature to adopt unanimously the suggestion of the minister of public welfare that a state institute for the study of labor problems and industrial hygiene be created The need of applying psychologic principles to all industries was discussed at length, and special reference was made to the excellent results secured in America by the introduction of a practical system of psychology—more particularly, the Taylor system The Greater Berlin Street Railway Company, by training motormen in accordance with modern psychologic, scientific principles, effected a saving of 12,000,000 marks for the last fiscal year, while the number of accidents was also materially decreased With greater efficiency, a saving of 10 per cent in the amount of electric current required was brought about, and the wear and tear on the rolling stock and the roadbed was distinctly reduced Another great gain lay in the fact that with the application of scientific, psychologic principles the motormen and conductors could be trained for the work in one third the time formerly required

Marriages

HERBERT FAY HEMPSTEAD JONES to Miss Edna Marie Penick, both of Little Rock, Ark, June 15

J HOWARD VAN NESS to Miss Elizabeth Maentz, both of Allegan, Mich, at Battle Creek, June 15

MERLIN JONES STONE, Ogden, Utah, to Miss Corynne Constance Wall of Temple, Texas, July 8

JAMES RUSSELL YOUNG, JR, Rexburg, Idaho to Miss Eve English of Pocatello, Idaho, recently

ELLSWORTH JOHNSON, Windom, Minn, to Mrs Carolyn H Clark of St Cloud, Minn, in June

LEO JOSEPH STARRY, Oklahoma City, to Miss Maree Patch of Colorado Springs, Colo, June 21

WILLIAM H SPEITH, Indianapolis, to Miss Viva Pearl Wilson of Roachdale, Ind, June 25

ELMER HARRY HANSEN, Minneapolis, to Miss Mary E O'Brien of Cloquet, Minn, in June

LOUIS CHARLES LEHR Washington, D C, to Mrs Eleanor Moale Hillen of Baltimore, July 1

BURTIS E GOLDBERG to Miss Helen Cleave Anderson, both of Arlington, N J, June 29

ALFRED H BUDGE, Boise, Idaho, to Miss Bernice Rickert of Waterloo, Iowa, June 30

GEORGE STARR WHITE, Los Angeles, to Miss Deborah Logan of Oxnard, Calif, recently

THOMAS H MORRIS to Miss Ruth Compton, both of Plainfield, N J, June 6, 1922

ALBERT G PETERS Pontiac, Ill, to Miss Evelyn Cole of Decatur Ill June 17

WILLIAM F CLEVENGER to Miss Louise M Weaver, both of Indianapolis, July 5

ATTILIO ROBERTIELLO, New York, to Miss Eleonora Candela of Brooklyn, July 5

LEON S SEIDLER to Miss Edith Freudenberg, both of Chicago, July 2

ROY SEXTON to Mrs Mary Harvey, both of Streator, Ill, July 3

Deaths

Edmund James Armstrong Rogers ⊕ Denver, McGill University Faculty of Medicine, Montreal, 1881, L R C P and L R C S, Edinburgh Scotland, 1881, formerly a civil engineer, emeritus professor of surgery at the University of Colorado, surgeon to St Luke's Hospital and the Colorado Sanitarium, served three terms on the state board of health governor of the Colorado Society of Colonial Wars, 1900, president of the Colorado State Medical Society, 1903-1904 member of the British Medical Association and the American Climatological Society, died, July 3, aged 70

William John Maroney ⊕ New York, Yale University School of Medicine, New Haven, Conn, 1890, member of the New York Obstetrical Society, formerly assistant professor of obstetrics at the Fordham University School of Medicine, on the staffs of St Ann's Maternity Hospital, the New York Foundling Hospital and St Vincent's Hospital of the City of New York, where he died, July 10, aged 49, following an operation for perforated diverticulum of the sigmoid

Gaylor Joel Pettit ⊕ New York, New York Homeopathic Medical College and Hospital, New York, 1896, U S Naval Reserve Corps, in charge of the naval hospital at Portsmouth, Va, during the World War, died of strangulation caused by abscess of the larynx, on board the U S S *St Paul*, of which he was ship surgeon, at Hamburg, Germany, June 21, aged 55

George Eaton Simpson ⊕ Howard, R I, Medical School of Maine, Portland, 1899, member of the American Medico-Psychological Association and the New England Society of Psychiatry, for sixteen years assistant superintendent of the State Hospital for Mental Diseases, died, July 9, aged 41, following a long illness

Calvin Pratt, Bridgewater, Mass, Medical School of Harvard University, Boston, 1866, member of the Massachusetts Medical Society, Civil War veteran, formerly president of the board of trustees of the Bridgewater Academy, and consulting physician of the Bridgewater State Farm, died, June 17, aged 78, from heart disease

David Michael Roudabush, Williamsport Pa, Hahnemann Medical College and Hospital of Philadelphia, 1906, member of the Medical Society of the State of Pennsylvania, aged 42, was electrocuted, July 3, when he accidentally picked up a live wire in the cellar of his home

Lucian Nicholson, Paris, Texas Chicago College of Medicine and Surgery Chicago, 1915, member of the State Medical Association of Texas, on the staff of the Sanitarium of Paris, city health officer, died, May 4, aged 33, from multiple abscesses of the lungs

William James Wanless, Shangli-Miraj, India, University of the City of New York 1889, formerly of Toronto, medical missionary for the Board of Foreign Missions of the Presbyterian Church in the United States, died recently in India, aged 56

Charles Adams Gray, Hinsdale, N H, Bellevue Hospital Medical College, New York, 1869, member of the New Hampshire Medical Society and formerly president of the Connecticut River Valley Medical Association, died, April 27 aged 75

William Thomas Jamison, Los Banos, Calif, Barnes Medical College, St Louis, 1897, member of the Medical Society of the State of California, died, June 27, aged 51, at the St Francis Hospital, San Francisco, from chronic interstitial nephritis

William Richard Jackson ⊕ Mobile, Ala, Medical College of Alabama, Tuscaloosa, Ala, 1888, member of the staff of the City Hospital formerly professor of surgery at University of Alabama School of Medicine, died suddenly, July 3, aged 58

Jacob Irving Roe ⊕ Wilkes-Barre, Pa Medical Department of Columbia College, New York, 1875, on the staff of the Wilkes-Barre Hospital, died, July 2 aged 67, at the Pennsylvania Hospital, from bronchial pneumonia

Eben Stedman Cox, Galveston, Texas, Louisville Medical College, Louisville Ky, 1884, member of the State Medical Association of Texas, for twenty years health officer of Galveston County, died suddenly, June 24, aged 63

⊕ Indicates Fellow of the American Medical Association

William L Dunn, Glade Spring, Va , Medical College of Virginia, Richmond, Va, 1863, member of the Medical Society of Virginia, Confederate veteran, died, June 26, aged 82, following a long illness

William Henry Merry, Lynn, Mass , Medical Department, University of Louisville, Louisville Ky, 1876, surgeon captain with the British Naval and Military Veterans' Association of Massachusetts, died, June 27, aged 71

Adrian C Karsten, Horicon, Wis , Wisconsin College of Physicians and Surgeons, Milwaukee, 1897, member of the State Medical Society of Wisconsin, died suddenly, July 1, aged 56, from cerebral hemorrhage

Waldo Percy Goff, Clarksburg, W Va , Jefferson Medical College, Philadelphia, 1894, member of the West Virginia State Medical Association, died suddenly, July 3, aged 51, from heart disease

William Henry Grotthouse, Columbus, Ohio, Miami Medical College, Cincinnati, 1893, member of the Columbus Academy of Medicine, also a druggist, died, June 30, aged 53 from carcinoma

Stephen Longstroth Richards ⊕ Salt Lake City, Utah, Ensworth Medical College, St Joseph, 1893, on the staff of the Latter Day Saints' Hospital, died, July 5, aged 68, following a long illness

Robert Stewart, Chicago, Rush Medical College, Chicago, 1895, on the staff of St Bernard's Hospital, died, July 13 aged 58 at the Wesley Memorial Hospital, from tumor of the brain

Robert Cushman Flagg, Middlebury, Vt , University of Vermont College of Medicine, Burlington, Vt, 1906, member of the Vermont State Medical Society, died, July 1, aged 44

Alexander Kemp De Jarnette ⊕ Sheridan, Wyo , University of Louisville Medical Department, Louisville, Ky, 1916, died, June 4, aged 32, at Colorado Springs, Colo

Matthew Henry Ellis ⊕ Albany, Ore , University of Michigan Medical School, Ann Arbor, 1879, veteran of the Spanish-American War, died, May 31, aged 64

Roscius Morse, Estacada, Ore , University of Buffalo Department of Medicine, 1907, died, May 11, aged 46, at St Vincent's Hospital, Portland

William V Hall, Denton, Texas, Medical Department of the University of Tennesse, Nashville, 1884, Confederate veteran, died, June 21, aged 82

Thomas Joseph Francis Cox ⊕ Sacramento Calif , Medical Department, University of California, San Francisco, 1896, died suddenly, July 5, aged 49

John Thomas Frawley, Perry, Ohio, Cleveland University of Medicine and Surgery, Cleveland, 1896, died, June 7, aged 54, from pneumonia

Albert Benjamin Herrick, San Diego, Calif , University of Michigan Medical School, Ann Arbor, 1879, died, June 28, aged 70, at Santa Rosa

Jesse O Davy, Springfield, Ohio, Medical College of Ohio, 1869, member of the Ohio State Medical Association, died, June 23, aged 71

Charles A Groff ⊕ Philadelphia, Jefferson Medical College, Philadelphia, 1875, died, July 3, aged 75, from disease of the liver

Otto Henry Rohde, Los Angeles, Eclectic Medical College of the City of New York, 1896, died, June 24, aged 76, at Hollywood

Thomas C Craig, Easton, Kan , Medical College of Virginia, Richmond, Va , 1867, Confederate veteran, died, June 29, aged 78

James C Sharp, Alma, Ark , Medical Department University of Tennessee, Nashville, Tenn, 1892, died July 7, aged 53

Lawrence Whiteford Nettles, Camden S C , College of Physicians and Surgeons, Baltimore, 1885, died, June 26, aged 69

Abner B Everitt, Toledo, Ohio, Medical Department of Western Reserve University, Cleveland 1883, died, July 3, aged 75

William Dillon, Urbana, Ill , Medical College of Ohio, Cincinnati, 1882, died, July 4, aged 72, following a long illness

Wellman Calvin Blake, Bellingham Mass , Dartmouth Medical School, Hanover, N H , 1884, died, June 27, aged 63

Broer Rollo Johnson ⊕ Cadillac, Mich , Rush Medical College Chicago, 1920, died, July 8, aged 27

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

HAELEPRON TABLETS NOT ADMITTED TO N N R

Report of the Council on Pharmacy and Chemistry

The Council has adopted the following report declaring Haelepron Tablets inadmissible to New and Nonofficial Remedies W A PUCKNER, Secretary

Haelepron Tablets are made by Bodenstein and Gaslinsky, Berlin, Germany, and sold in the United States by the Haelepron Sales Co, New York The following nonquantitative statement of the composition of Haelepron Tablets appears on the trade package

Haemaglobin Lecithin Calc Lact. Protein vegetab Ferr sacch Ferr pyrophos

A similar statement appears in the advertising except that here the preparation is said to contain "Protein animal and vegetable" and instead of one calcium salt, "Calc Lact," and two iron salts, "Ferr sacch, Ferr pyrophos," being claimed the presence of two calcium salts, "calcium lactate" and "calcium saccharate," and one iron salt, "pyrophosphate of iron," is declared

In the information sent the Council, the following report of an analysis of Haelepron Tablets is given

Water 8 86 Nitrogen (Protein) 48 10 Ether Extract (Fat) 7 08 Mineral Salts (calcium lactate saccharate Pyrophosphate of Iron) 10 61 Cellulose 1 93 Extractive substance (non nitrogenous and not cellulo e) 23 42

In the circular it is claimed 'The Protein substances are chiefly blood albumin (Haemoglobin) besides the proteids of Milk, Egg and certain plants And the mineral residue consists altogether of a variety of lime and iron salts" According to the Haelepron Sales Co, this indefinite mixture is Indicated whenever nutrition impaired, in nervous conditions and dysemias" The indiscriminate use of the tablets is suggested by the declaration that they are "tolerated by everyone" and their use does not "interfere with other medicines taken simultaneously"

The Council finds Haelepron Tablets inadmissible to New and Nonofficial Remedies because (1) their composition is indefinite and semi-secret, (2) the recommendations for their indiscriminate use are unwarranted, (3) the name is not descriptive of their composition and (4) they are an irrational and useless combination which can have little if any effect on the conditions for which they are recommended

PLATT'S CHLORIDES DECEPTION OR IGNORANCE?

An advertisement for Platt's Chlorides calls attention to the fact that chlorin antiseptics are at present in favor The statement is then made that "chlorid of lime" is perhaps the best known of the older chlorin antiseptics To quote

As prepared and combined (with other related salts) under the name of Platt s Chlorides it [chlorid of lime '] has served well for years for disinfection purposes about the house Platt s Chlorides is still the choice of a great *many discriminate [Sic!]* people and is to be found in homes and in hospitals *everywhere* In fact with our present appreciation of chlorin this preparation is sure to win more friends than ever before

Chlorid of lime" is an unscientific name for calcium hypochlorite or chlorinated lime (the pharmacopeia gives it as a synonym for *calx chlorinata*) An analysis of Platt s Chlorides made several years ago in the A M A Chemical Laboratory failed to show any active (free) chlorin derivative True chlorids were present, but chlorin in the negatively

charged (combined) form as in chlorid (Cl^-) is not known to have any germicidal effects, it is active only when it is in a positively charged form as in the free state ($^-Cl^-Cl^+$) or in hypochlorites and derivatives (HO^-Cl^+) A recent specimen of Platt's Chlorides has also been tested for hypochlorites The chemical laboratory again reports the absence of active chlorin (Cl^+) compounds, further it points out that hypochlorite could not be present as the product contains considerable iodid which would be incompatible with hypochlorite

The question naturally arises Is this misinformation concerning Platt's Chlorides a case of deception or is it merely ignorance due to the fact that the household phrase "chlorid of lime" resembles the name calcium chlorid, the latter being present in Platt's Chlorides? The evidence points to deception because the label on the bottle states (in accordance with the requirement of the federal law) that calcium chlorid in Platt's Chlorides is *inert* material!

Platt's Chlorides has been the subject of previous reports The Council on Pharmacy and Chemistry declared it "inadmissible to New and Nonofficial Remedies because its composition is uncertain and indefinite and because the claims made for it are exaggerated and misleading"

Correspondence

NUTRITION IN RICKETS

To the Editor —Dr A F Hess, in his Cutter Lecture at Harvard a few weeks ago, remarked that "advance in our knowledge of rachitis promises to be greater during this decade than through the preceding 250 years" He asserts that the dietary deficiencies play a very significant part in the etiology of rachitis

A number of years ago, when I was connected with the West End Children's Hospital and Dispensary, Boston, we were having a large number of rachitic children in our daily clinics, a majority of them from among the colored population The superintendent, Dr H C Haven, informed me that he had made quite an exhaustive study of rachitis with especial reference to the causes of the disease, and he came to the conclusion at that time that environment, lack of sunlight and fresh air were the probable causes He stated that among the colored in Africa, in a climate to which they are adapted, there are no cases of rachitis

Three winters later while in the South, I studied the children of that warm climate who were in the fresh air and sunshine practically the year around, and I failed to find a case of rachitis among them I have no doubt that with a properly regulated diet with plenty of sunlight and fresh air, we have the best treatment for rachitis extant Surely sunlight is the enemy of disease

C S SCOFIELD, M D, Richford, Vt

"A PRACTICAL TROCAR AND CANNULA FOR REMOVING ASCITIC FLUID"

To the Editor —I have just read with interest the article contributed by Dr William W Duke (THE JOURNAL, July 8 p 134) in which he describes and illustrates an improved trocar and cannula He concludes his article by saying, "The advantages of this cannula would appear to offset its only disadvantage, slightly increased cost" This quotation impels me to write of an improvement I had made in a cannula about fifteen years ago, and following somewhat the lines of Dr Duke's instrument, but which can be had at practically no added cost to the instrument in common use

Two oval openings near the end of the cannula were made corresponding to the size of the inlet, and perfectly smooth, so that they could not interfere with the entrance of the trocar into the cavity to be drained To avoid weakening the lumen of the cannula, these openings were not placed opposite each other, or on the same level

When the cannula is in place, there is a continuous flow of the fluid until complete evacuation is accomplished

Dr Duke's instrument has, however, a distinct advantage in its added length, which affords a wider range of usefulness

J HARRIS PIERPONT, M D, Pensacola, Fla

"THE ALLEGED INSUSCEPTIBILITY TO INTOXICATION BY POISON IVY"

To the Editor —In THE JOURNAL, July 15, is a current comment in which the statement is made that, "contrary to the theory of 'desensitization' by internal administration of tincture of rhus, it appears that the susceptibility may be increased with successive intoxications"

The question of desensitization by internal administration of the tincture of the drug is unrelated to the question of increasing susceptibility to successive external exposure to the plant It is to be regretted that destructive criticism of the treatment by desensitization should be published without adequate clinical testimony, for many patients may, as a result, be deprived of the value of this treatment

In October, 1919, I published a short paper in THE JOURNAL on "Desensitization of Persons Against Ivy Poison" Since that time I have treated in the neighborhood of fifty patients who were susceptible to ivy poison, and most of whom were subject to yearly attacks In not a single patient has ivy poison developed since, when the treatment was carried out prior to exposure, in a number of cases the patient escaped an attack of ivy poisoning during the season when the medicine was taken, but was attacked the following season when the medicine was omitted

In my opinion, it is possible in practically all persons to prevent attacks of rhus dermatitis by taking, internally, ascending doses of a 1 per cent solution of the tincture, beginning with a drop, well diluted, and increasing to sixty drops a day The uniform success that I have observed with this treatment convinces me absolutely that persons can be desensitized during the period of administration of the drug, and usually for about a month after the cessation thereof

JAY FRANK SCHAMBERG, M D, Philadelphia

POSTGRADUATE STUDY IN VIENNA

To the Editor —The American Medical Association of Vienna wishes to announce the restoration of friendly understanding between their organization and the teaching-body of the University of Vienna A committee elected by the association, after an investigation of charges of discrimination against Americans, which were reported by members of our association, finds that these charges could not be substantiated

We further wish to state that, through the efforts of our committee, working with a like committee from the teaching body, sufficient numbers of book courses in English in all branches may be had at prices of from $3 to $5 an hour for the group taking such courses

JOHN J GELZ, M D,
BERNARD KAUFMAN, M D,
WILLIAM WILSON M D Vienna

Public Health in Spain —In a recent lecture, Dr Cesar Juarros, the Madrid neurologist, discussed sanitary conditions in Spain Tuberculosis has shown an increase in its mortality from 7,700 in 1911, to 8,200 in 1915, 9 800 in 1920 Typhoid fever showed a similar increase from 4,500 in 1911, to 5,100 in 1915, and 6,998 in 1920 A similar situation prevails as regards malaria and smallpox

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and addre s but these will be omitted on request

BLOOD TRANSFUSION

To the Editor —In the last examination of the National Board of Medical Examiners the following question was included Explain the dangers of transfusing an incompatible blood, and tell how you would determine whether or not the blood of A is compatible with that of B so that A s blood could be safely transfused into B

Plea e give an answer to this question and omit my name if published in THE JOURNAL G W H

ANSWER —The chief danger of transfusing an incompatible blood is based on the possibility that the blood transfused may contain iso agglutinins or isohemolysins for the blood of the recipient or that the blood of the recipient may contain bodies which agglutinate or hemolyze the cells of the donor's blood It is clear, therefore, that a donor should be chosen for the transfusion whose blood shows no interagglutination or hemolysis with the patient's serum and corpuscles If such a donor cannot be found, it is safer, as Kolmer states to use a person whose serum is agglutinative toward the patient s cells than one whose cells are agglutinated by the patient's serum Should an incompatible blood be transfused it is evident that agglutination may lead to the formation of emboli and thrombi, while the intravascular hemolysis may be associated with marked hemoglobinemia hemoglobinuria and an intense anemia of the pernicious type

A further danger to be considered in transfusion is the possibility of transmitting syphilis by this procedure Hence, the blood of the donor selected should have given several negative Wassermann tests

For the determination of compatibility of the blood of A with that of B, 2 or 3 c c of the blood of A is obtained by the usual serologic method, and 0 5 c c placed at once in a centrifuge tube containing 5 c c of a 1 per cent solution of sodium citrate in physiologic sodium chlorid solution The remainder of this blood is placed in a small, dry test tube, and the serum is allowed to separate From B (the recipient) 3 or 4 c c of blood is obtained in the same manner, and the same procedure is followed with this blood as with that of A (the donor)

The sodium citrate tubes are centrifuged, the supernatant fluid is pipetted off and the cells are washed again with physiologic sodium chlorid solution This procedure is repeated if necessary in order to free the cells from every trace of serum After the final washing enough physiologic sodium chlorid solution is added to the cells to make a total volume of 5 c c

The serum tubes are centrifuged and the clear serum is separated This serum should be clear, and show no trace of hemolysis The following series of tests should then be set up, the small serologic test tubes being used

1 Four drops of A s (donor s) serum plus 1 drop of B s red cell emulsion
2 Four drops of B s (recipient s) serum plus 1 drop of A s red cell emulsion
3 Control Four drops of A s serum plus 1 drop of A s red cell emulsion
4 Control Four drops of B s serum plus 1 drop of B s red cell emulsion
5 Control One drop of A s red cell emulsion plus 4 drops of physiologic sodium chlorid solution
6 Control One drop of B s red cell emulsion plus 4 drops of physiologic sodium chlorid solution

One cubic centimeter of physiologic sodium chlorid solution is added to each tube and the tubes are shaken and placed in the incubator for two hours being inspected about every half hour Agglutination in Tubes 1 and 2 may be recognized macroscopically by the clumping of the red cells Hemolysis is noted as in the Wassermann test If there is any question about hemolysis, let the tubes stand in the icebox over night Tubes 3, 4 5 and 6 should show neither agglutination nor hemolysis In the interpretation of this test, if there is no reaction (agglutination or hemolysis) in Tubes 1 and 2 then the blood of A is compatible with that of B and may safely be used for the transfusion

A quicker and less elaborate method for determining the compatibility of the blood of A is that of Minot From a prick in the finger or ear, 9 drops of blood from B and 1 drop from A are collected and allowed to fall into a small test tube containing 3 or 4 drops of a 1 5 per cent sodium citrate solution in physiologic sodium chlorid solution In another tube, containing the same amount of the sodium citrate solution, 9 drops of blood from A and 1 drop from B are collected The blood in each tube is mixed by shaking the tubes and allowing them to stand for fifteen minutes At the end of this time, the two tubes are examined for agglutination by means of the microscope

OXALIC ACID IN FOOD

To the Editor —What foods contain calcium oxalate?

J R SCOTT M D Nonkanahwa N Y

ANSWER —Calcium oxalate is the usual form in which oxalic acid appears in the diet The amount of oxalic acid in different articles of food in parts per thousand, as determined by Esbach is

Black tea infused five minutes	2 060
Cocoa powder	3 520 to 4 500
Pepper	3 250
Coffee	0 127
Parsley	0 006
Common beans	0 158
Potatoes	0 046

BACHELET ELECTRO MAGNETIC THERAPEUTIC WAVE GENERATOR

To the Editor —I am enclosing a mass of wonderfully attractive literature on the Bachelet Electro-Magnetic Therapeutic Wave Generator Although declared to be radioactive the pamphlet states that any physician may use the Bachelet without fear of injury to himself or his patient That this last statement is quite true I do not doubt but it seems inconsistent with the manufacturer s claims of radioactivity In fact it seems to me that the manufacturer is treading perilously near the path that leads to federal fraud orders debarring him from the use of the mails

The enclosed literature should make wonderful mental pabulum for the layman and pseudoscientific physician with a leaning toward questionable practices but I would like to hear from you as to its real value—if it has any which I doubt

JOHN H SCHAEFER M D Clovis Calif

ANSWER —So far as one can judge from the advertising matter and literature, the 'Bachelet Electro-Magnetic Therapeutic Wave Generators, Radio-Active' device (price, from $50 to $350) is simply a form of induced current Aside from the psychic effect of the apparatus, it is hard to see why results from it would be any more beneficial than those obtained from a small faradic coil costing about $5 Essentially, the only results obtained from the faradic induced current are two first a stimulation of the peripheral circulation, second muscle contraction when the lower motor neuron is intact The claims made for the 'Bachelet Electro-Magnetic Therapeutic Wave Generators Radio-Active' make one wonder whether this concern has had its literature written by a copy-writer trained in the "patent medicine' school of advertising

Book Notices

THE PATHOLOGICAL GALL BLADDER ROENTGENOLOGICALLY CONSIDERED By Arial W George, M D and Ralph D Leonard A B, M D Annals of Roentgenology, Volume II Cloth Price $10 net Pp 198 with 137 illustrations New York Paul B Hoeber, 1922

The authors of this atlas on roentgenologic studies of the gallbladder are too well known to those acquainted with medical literature to require any introduction It would be surprising, therefore, if the reader were not brought in contact with the best there is to be had on this particular subject One must marvel at the splendid technic that enables the collaborators to depict in such a clear and unmistakable way pathologic conditions which have been verified time after time by exploratory operation The text is in English, French and German The print, paper and reproductions are excellent Emphasis is laid on the careful preparation of the patient for examination and a description of the technic is given A statement of the approximate amount of amperage is omitted The authors recommend a high milliamperage with a medium focus radiator type of tube The latter tubes, however, for the purpose of conservation, are restricted to 30 milliamperes Hence a more explicit statement at this point might be desirable What would appear to be especially interesting is the subject of indirect evidence of disease of the gallbladder So well known are the difficulties underlying the differential diagnosis of diseases of the gallbladder from duodenal ulcer that any technic, whether clinical or laboratory, that aids in solving this trouble would be widely welcomed by all Not every one can be a Leonard or a George, but every one can profit by their experience A study of their technic and results will be of great help to the physician in his daily struggle with this baffling problem

UEBER DIE ALTERSSCHATZUNG BEI MENSCHEN Akademische Antritts rede bei der Uebernahme der Professor fur innere Medizin in Erlangen Von L R Muller Direktor der Medizinischen Klinik in Erlangen Paper Price 132 marks Pp 62 with 87 illustrations Berlin Julius Springer 1922

Probably the most valuable feature of this little book is the illustrations showing the appearances of the human body at various ages It is emphasized that, at present, only general estimates can be made of the age of human beings by the study of the bodily conditions No scheme has been devised by which one can evaluate correctly the varying influences of the many different factors that determine the rate of senescence The book should be of special value to insurance examiners and others who are concerned with the determination of the expectancy of life

PATHOLOGISCHE HISTOLOGIE Ein Unterrichtskurs fur Studierende und Aerzte Von Dr Max Borst O O Professor der Allgemeinen Pathologie und der Pathologischen Anatomie an der Universitat Munchen Paper Price 250 marks Pp 371 with 238 illustrations Leipsic F C W Vogel, 1922

In this excellent book the author presents a beautifully illustrated description of the pathologic histology of the principal diseases based on the experience of twenty-five years in giving courses to medical students The book should prove a reliable and useful guide to the study of pathologic histology The illustrations merit a word of special praise All are drawn by W Freytag in Wurzburg from original preparations most of them in colors They represent a noteworthy artistic and technical achievement

ANLEITUNGEN ZU DEN PRAPARIERUBUNGEN AN DER MENSCHLICHEN LEICHE Von Georg Ruge O O Professor der Anatomie und Direktor der Anatom Anstalt in Zurich Fifth edition by Dr med Walther Felix O O Professor der Anatomie und Direktor der Anatom Anstalt in Zurich Cloth Price 15o mark Pp 724 with 267 illustrations Leipsic Wilhelm Engelmann 1921

The value of this work is in the highly essential correlation of the technical minutiae of the study of human anatomy in the dissecting room with that in the larger textbooks and atlases, aiming to guide the student in correct methods of orderly dissection and exposure The book, including the covers, is just a little more than ar inch thick, notwithstanding the large number of pages, an accomplishment in book making which other publishers should imitate

Miscellany

VACCINATION IN THE PHILIPPINES

The statement made by the antivaccinationists that vaccination has proved a failure in the Philippines as a means of preventing smallpox is the exact opposite of the facts This is conclusively shown in an authoritative statement in the current number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by Dr Victor G Heiser, consultant in health to the Governor General of the Philippines, and Dr Charles N Leach of Manila It is true that lately there was a large increase of deaths from smallpox in the Philippines, coincidentally with a nominal existence of public vaccination, but this apparent revival of smallpox is shown to have followed a widespread neglect of vaccination

Previous to the American occupation of the Philippines there were 40 000 deaths a year from smallpox in the islands When the Americans introduced compulsory vaccination the disease disappeared wherever vaccination was applied The death rate from smallpox in the provinces surrounding Manila fell from 6,000 annually to not one For seven years prior to 1914 there was not one death from smallpox in the city of Manila Then laxity began to prevail, and it is proved that the local officials began to report vaccinations where none or very few had taken place Vaccination is under any circumstances a difficult matter in Philippine country districts The average temperature is from 90 to 100 degrees all the year round Ordinary vaccine remains potent only a few days without ice, and outside of the cities it is impossible to procure ice This condition of things prevented the universal application of vaccination in the Philippine country districts, with the result that in these districts the disease was kept alive Finally it was discovered that while in one province the officials, with cheerful enthusiasm, reported 50,000 more vaccinations than there were inhabitants in the province, the vaccine virus was found to have been thrown into waste-paper baskets and other receptacles of rubbish This condition of things was exposed, active vaccination was resumed, and the islands are again almost free of smallpox

It was upon the temporary revival of smallpox consequent upon the neglect described, intentional in some cases and unavoidable in others, that the antivaccinationists based the claim, which they are still making, of the "failure of vaccination in the Philippines" The simple fact is that, in the recent smallpox epidemic, 93 per cent of the deaths were shown to have occurred among the unvaccinated As matters now stand, vaccination is proceeding on a better scale than ever, for methods have been discovered for making vaccine that will remain potent under tropical conditions

If in spite of this renewal of the protection afforded the prevalence of smallpox should continue, there might be some claim for the assertion that 'vaccination is a failure in the Philippines' As a matter of fact, the resumption of active vaccination has already terminated the epidemic What Dr Heiser and Dr Leach say about the matter appears perfectly true, namely, that those who have advocated the abolition of vaccination have been the cause of many of the deaths among the unvaccinated, and in view of the frightful loss of life that may occur in smallpox epidemics they are assuming a grave responsibility indeed if they continue their campaign" —Editorial, *Boston Evening Transcript*

Treatment of Insomnia.—There is no specific for insomnia The underlying cause must be ascertained and removed before a cure can be expected Even then the ability to sleep often needs to be wooed back There is an art in making yourself comfortable and also an art in procuring pleasant dreams— *Nation's Health* 4 212 (April) 1922

Courts Selecting Physicians to Make Examinations

(Landis v Wichita Railroad & Light Co (Kan) 203 Pac R 1109)

The Supreme Court of Kansas, in affirming a judgment in favor of the plaintiff in this personal injury case, says that, just before the impaneling of the jury, the defendant's attorneys asked the trial court to appoint two or three physicians of its own choosing to examine the plaintiff The plaintiff being willing to be examined by two physicians chosen by the defendant, the court refused to make any selection on its own account The defendant complained of this refusal, arguing that the report of an examination would have carried more weight with the jury if made by persons selected by the court Merely to illustrate the difference of opinion on the subject, and without approving the doctrine, it may be mentioned that a statute requiring the court to select expert medical witnesses to testify in murder cases has been held unconstitutional, in part, at least, because of the very fact that the jury would be likely to give exceptional credence to their testimony, the court saying

> The expert witnesses provided for by this section testify under a sanction which gives to their testimony practically the same weight as if it were delivered by the court itself and if that testimony being against the accused were either wilfully or ignorantly mistaken its baneful results would be appalling To give to the testimony of a witness or witnesses this extraordinary certificate of candor ability and truthfulness while the other testimony in the case must be judged by ordinary standards is to subvert the very foundations of justice (*People v Dickerson* 164 Mich 148 129 N W 199)

The Supreme Court of Kansas has held that, in some circumstances, the trial court has discretionary power to appoint physicians to make an examination of a person whose condition is in controversy, but, if a refusal to do so can ever amount to an abuse of discretion, the court finds no basis for holding such to have been the case here In other words, it is held here that no abuse of discretion is shown in the refusal of the trial court to select physicians to examine a plaintiff the extent of whose injuries was in issue, the plaintiff being willing to be examined by physicians chosen by the defendant

A Bequest for Teaching Medicine Held Void as Against Public Policy

(In re Hill's Estate (Wash) 204 Pac R 1055)

The Supreme Court of Washington says that this action was brought for the purpose of testing the validity of a paragraph of the will of one S G Hill, deceased In that paragraph, the testator directed the trustee named in the will to invest the residue of the estate in bonds and apply the income in perpetuity after deducting the expense of handling the trust, in order to pay for the services of a competent homeopathic physician or physicians, who should give instruction at or near some reputable homeopathic school of medicine in the United States, to demonstrate to students the effectiveness of homeopathic remedies and treatment in cases of chronic diseases, the physician presenting these lectures and clinics to use as textbooks and confine the instruction to the proposition, principles and methods laid down in Hahnemann's "Organon of the Art of Healing,' "The Nature of Chronic Diseases (Hahnemann's), and J T Kent's "Lectures on Homeopathic Philosophy,' and should also be required to teach his students the use and application of Kent's 'Repertory of Homeopathic Materia Medica" Further provision was made to the end that there should be no subversion or distortion of the instruction and information which the testator wished to become available to such students in medicine as might desire to receive the same

On the trial there was testimony by physicians who practiced according to the methods and principles of the allopathic school, and also those who practiced according to the principles and methods of the homeopathic school Disregarding entirely the testimony of the allopathic physicians, and looking only to the evidence of those testifying who belonged to the homeopathic school, the great weight of the evidence sustained the finding or conclusion of the trial court that, if the books mentioned were taught without subversion or distortion, it would lead to sickness and death, and would deprive ailing persons from receiving treatment which is recognized by the modern homeopathic school It might be said that the evidence almost conclusively established that fact The evidence showed that, since the books mentioned were written, there had been a large development in medical science as practiced by the homeopathic school, that the books were not modern, and that if the principles and methods there taught only were applied in the healing of disease, it would be detrimental to the public health

Since the evidence showed that the teaching of the books without a subversion or distortion would be inimical to the public health, the question arose as to whether the bequest for that reason was void It can hardly be doubted that, if it were a bequest which tended to support an immoral purpose as recognized by modern standards of correct conduct, the will would be void for that reason If a will making a bequest for an immoral purpose should be declared void, by the same course of reasoning it would follow that, when providing for the teaching of medicine which would be detrimental to the public health it would likewise be illegal and could not be carried into effect In other words, in such a case, it becomes the duty of the court to declare that the bequest is void on the ground of public policy If the bequest had not been limited to instruction in the books mentioned without subversion and distortion, and had recognized that the principles and methods of those books were to be taught in connection with the modern methods of the homeopathic school, an entirely different question would be presented As the record stands, the bequest and the teachings required thereby are not supported by any modern school of medicine It was contended that the bequest was void also on other grounds, but these need not be considered because the fact that the bequest was void on the ground of public policy disposed of the case

Implied Authority to Make Exploratory Incisions and Extend Operation

(King Carney (Okla) 204 Pac R 270)

The Supreme Court of Oklahoma, in reversing a judgment obtained by the plantiff, and remanding the cause for a new trial holds that the general directions of a patient to his surgeon, authorizing him to perform an operation for the cure of a specific physical ailment, not only authorizes the surgeon to operate, but also, by clear implication authorizes him to diagnose the case for the purpose of discovering for himself the exact cause of the malady he is called on to treat, and to make whatever initial exploratory incisions may be necessary for this purpose If, in the course of an operation to which the patient consented, the physician discovers conditions not anticipated before the operation was commenced, and which, if not removed, will endanger the life or health of the patient, he will, though no express consent was obtained or given, be justified in extending the operation to remove and overcome them

This was an action for damages for an alleged unauthorized operation The plaintiff, Mrs Carney, the court says, had been married twice and had one child by her first husband After her second marriage she bore no children, but suffered from several miscarriages Wishing to correct this condition, she called on defendant King, told him that her family physician had stated that her condition was caused by laceration of the uterus and said "I want to be fixed so I can bear children, and we will never be happy without that" The defendant testified that he made an incision in the plaintiff's abdomen and an examination from which he found that the ovaries were badly affected, that there were many adhesions around the ovaries intestines and uterus, that the fallopian tubes were sealed, both ends being full of pus, and that, on discovering the condition, he removed the diseased organs and the contiguous infected tissues Up to

this point the defendant and the surgeon who assisted with the operation were permitted to testify without objection On the witnesses being asked questions tending to prove that the fallopian tubes, the ovaries and surrounding tissue were so badly diseased that it was necessary to remove the diseased organs and affected parts to preserve the plaintiff's life and health and that it would have been dangerous to her life and health not to do so, objections were made and sustained by the trial court But the supreme court holds that the state of the pleadings warranted the introduction of testimony tending to show an emergency, and that the exclusion of this testimony constituted reversible error

It was contended that, under the pleadings and the proof the plaintiff's directions to the defendant were so limited that he was authorized only to perform the simple operation of mending the laceration of the uterus, which is properly performed through the vaginal opening But the plaintiff's specific directions to the defendant, I want to be fixed so I can bear children, and we will never be happy without that," it seems to the supreme court, not only authorized he defendant to cure the condition, if possible, but by clear implication authorized him to diagnose the case for the purpose of discovering for himself the exact cause of sterility and to make whatever exploratory incisions might be necessary to accomplish this purpose It is quite clear that making the initial incision in the plaintiff's abdomen was a proper and necessary step along this line And the mere fact that the plaintiff may have believed, or had been advised by her family physician that her condition was caused by a laceration of the uterus did not relieve the operating surgeon of the duty of discovering for himself the cause of the physical defect he was called on to remedy When this conclusion is reached, the relevancy of the testimony excluded becomes clearly apparent

Validity of Act Prohibiting Prescribing of Beer

(Falstaff Corporation Allen et al (U S) 278 Fed R 643)

The United States District Court, in Missouri, in holding valid the amendment to the Volstead Act providing that only spirituous and vinous liquors may be prescribed for medicinal purposes, says that counsel for the complainant disclaimed in behalf of beer any medicinal value or property whatever They contended that this amendatory act invaded the inviolable rights of natural liberty, and that the Eighteenth Amendment to the Constitution could not, and as a matter of law did not confer on Congress the authority to say what particular thing or agent might or might not be prescribed as a medicine, by physicians residing in the several states Courts take judicial notice that beer of the sort here involved is an intoxicating liquor, but they do not judicially notice whether beer is or is not valuable as a therapeutic agent It followed, then, that, for the purpose of this case the beer which the complainant desired to make and sell without any interference from the defendants must be regarded as an intoxicating liquor which possessed no recognized medicinal value whatever In the final analysis, it might well be insisted that the Eighteenth Amendment does not in terms forbid the use of beer as a food, but it will hardly be contended that its use for such a purpose can be permitted in the face of this amendment, and the statutes passed by virtue thereof, even though chemical analysis discloses that it possesses some food value and even though in other times it may have constituted, to many, both food and drink In other words, since the adoption of the Eighteenth Amendment, the privilege of drinking beer is no longer governed by the state of mind of him who drinks it, for, since it is an intoxicating liquor, its use is forbidden by the amendment When beer is used as a drink it necessarily follows that it is so used either as a beverage, or as a medicine If it has no value as a medicine, then when it is used as a drink it is used as a beverage, and this the Eighteenth Amendment and the laws passed thereunder forbid Color is lent to the appropriateness of the restriction here complained of by the fact that a large number of the states have deemed it absolutely necessary to pass laws which prohibit the prescribing for medicinal purposes of any intoxicating liquors whatever, save alcohol, and those statutes, thus restricting the privileges of physicians, have been upheld in every case so far as this court's examination of the holdings extends Before the effective date of the Eighteenth Amendment, the Supreme Court of the United States upheld, in *Ruppert v Caffey*, 251 U S 264, 40 Sup Ct 141, the war-time prohibition definition of an intoxicating liquor as being any liquid which contained more than one-half of 1 per cent of alcohol, and held in effect, that Congress, in the light of what experience had demonstrated to the several states to be necessary in enforcing prohibition, could arbitrarily declare a fact to exist, wherefore this case should not be differently decided if the question as to beer having a medicinal value were directly involved If it be that the power conferred on Congress by the Eighteenth Amendment had the effect to narrow, or wholly wipe out, constitutional rights and guaranties heretofore deemed vested and inviolable, the situation may be regrettable, but it canot be helped The people may be mistaken, their course may be tending toward restrictions of human liberty, but under our form of government, the majority rules, and when they change the organic law, this change must stand, and be fairly construed and honestly enforced, until it, in turn shall be again changed in due and legal form

Statutes Relative to Privileged Communications and Vital Statistics

(Hunter v Hunter et al (Miss) 90 So R 440)

The Supreme Court of Mississippi, Division A, reverses a decree that was rendered in favor of the contestants of the will of one Hunter, and remands the cause for a new trial because the physician under whose care the testator was for about two weeks prior to his death was permitted to testify that the testator, who made the will a few days before his death, was afflicted with senile dementia The court says that it was error to admit the testimony of the physician, it was a privileged communication of the patient under his charge, which could not be disclosed except at the instance of the patient It was argued that the statute relative to privileged communications was repealed by implication by the enactment of the law creating a bureau of vital statistics a section of which law provides that any copy of the records of birth, sickness or death, when properly certified to by the state registrar of vital statistics, to be a true copy thereof, shall be prima facie in all courts and places of the facts therein stated But the point made did not arise in this case, because no certificate of the registrar showing the death or sickness of the testator was offered as evidence in the case So far as the question was before this court in the present case, the court holds that the privileged communication statute was not repealed by the vital statistics act unless it was repealed to the extent that a registrar's certificate, made up from statistics or information obtained from the attending physician of the patient may be introduced in evidence to show the character of sickness or cause of death of the patient But the court does not decide at this time how far and to what extent the recent act modifies or annuls the former statute, because the question did not properly arise in this case

*Febrile Stages in Chronic Nephritis Their Significance as Observed by Functional Renal Tests J O Ritchey Indianapolis —p 882
Brachial Monoplegia Due to Thrombosis of Subclavian Vein G Wilson Philadelphia —p 899

Quinidin in Auricular Fibrillation — In approximately 50 per cent of cases, quinidin, as it is used at the present time, will restore the normal rhythm in the fibrillating auricles Lewis says The usefulness of the drug from the clinical standpoint is limited The chief limitation consists in the early and very frequent resumption of auricular fibrillation Lewis deprecates the general use of the drug He urges that it should be employed only under strictly controlled conditions, it is a treatment emphatically for the wards rather than for use in an outpatient department

Rigid Salt Restriction in Nephritis —The following results of the salt-free diet were noted by McLester The patient found the food unappetizing and usually ate but little The blood urea instead of decreasing showed a tendency to increase The blood chlorids irrespective of diet, varied but little, while the urine chlorids reflecting the degree of the patient's adherence to the diet fell to a very low figure The systolic pressure, as a rule, showed a moderate fall This fall was never marked In two of the patients there developed weakness and prostration to a distressing degree One of the patients suddenly experienced retinal hemorrhages and other fundus changes at the end of two weeks of this diet From these observations, McLester concludes that the almost complete elimination of chlorids from the diet of patients with nephritis and vascular hypertension accomplishes little if anything, more than does the salt poor diet ordinarily prescribed

Diagnosis of Hemorrhagic Pachymeningitis — Headache, sudden in onset, with signs of meningeal and spinal root irritation when associated with a uniformly bright, bloody spinal fluid, Dunn says is suggestive of pachymeningitis hemorrhagica interna Repeated lumbar puncture has proved of therapeutic value

Aneurysm of Left Ventricle —Kahn reports two cases of aneurysm of the left ventricle In both cases the precordial pain was a prominent feature during the course of the illness but it was not of the typical sternobrachial radiating anginal character Although necropsy findings did show pericardial changes in both instances, clinically this was not diagnosed and it is difficult to state the exact period at which the pericarditis began The outstanding features in the two cases were (1) precordial distress and the prominent circulatory symptoms, (2) myocardial failure, hydrothorax, congestion and enlargement of the liver and congestion of the viscera, (3) electrocardiographic changes, indicating progressive disease in the myocardium, (4) striking similarity in the electrocardiographic records due to the involvement of the apical portion of the left ventricle in both instances, and (5) coronary obstruction involving the descending branch of the left coronary artery The necropsy findings showed aneurysm of the apex and wall of the left ventricle with pericardial adhesions A brief review of the recent literature on cardiac aneurysm is presented Wood's plea for the greater use of the electric cautery in the treatment of laryngeal tuberculosis is not a new idea, nor am I presenting any special technic Any sanatorium not equipped both in its personnel, and in its instrumentarium for the cauterization of tuberculous lesions of the upper respiratory tract is not giving its tuberculous patients the utmost of modern medicine, and the laryngologist who fails to avail himself of its advantages is not a proper person to treat this disease

Pancreatitis Following Mumps —Farnham reports a case of epidemic parotitis, which was followed by abdominal symptoms diagnosed as acute pancreatitis, and an operation showed a swollen, acutely inflamed pancreas with a large quantity of peritoneal exudate The organism isolated from the peritoneal exudate was *Streptococcus viridans*

Analysis of Cases of Epidemic Encephalitis — Approximately one fourth of the cases of epidemic encephalitis seen by Price terminated fatally Of the remaining three fourths approximately 61 per cent were left with persistent or permanent sequels Relapses were of frequent occurrence, bore no definite relation to the severity of the initial symptoms and could occur several months after apparent recovery Prognosis could not be determined from the character and intensity of the initial symptoms Change in the abdominal reflexes is a frequent and important symptom in epidemic encephalitis, probably not hitherto sufficiently emphasized Epileptiform attacks may occur as the sole manifestation of the infection Rest, quiet and care in preventing too early activity on the part of the patient are essential in the treatment of epidemic encephalitis

Febrile Stages in Chronic Nephritis —Many observers have noted the seeming part infection plays in the etiology of nephritis Ritchey's observations show that during febrile elevations, either due to infection or some other agent, there is a noticeable and oftentimes measurable depression in renal function A great majority of all cases of chronic nephritis manifest temperature elevations at times throughout the course (acute stages) In chronic nephritis, fever, with an associated increase in albuminuria, shows an added acute process While function is not consistently depressed in acute infectious fever, it is found to be so during febrile reactions in cases of chronic nephritis In chronic nephritis, as shown by fever with simultaneous untoward clinical symptoms and functional impairment as measured by phthalein excretion, urea and creatinin retention and signs of renal irritation as determined by albuminuria and sediment increase, there are superimposed acute processes The clinical findings of Ritchey's six cases, checked in two cases with necropsy findings would suggest that the course of chronic nephritis is determined by these added acute processes and that the prognosis depends in large measure on their cessation or continuation

Sanatorium Follow Up Studies D E Wiesner New York.—p 320
Practice of Artificial Pneumothorax by Hippocratic School A K Krause Baltimore.—p 327

Diagnosis of Pulmonary Tuberculosis —The history the temperature and loss of weight Craig says are findings of considerable value in the diagnosis of pulmonary tuberculosis A systolic blood pressure which is below the normal for the age of the patient is a very suggestive finding

Causes of Fall in Tuberculosis Death Rate —It is suggested by Emerson that among the possible causes of the decline in the death rate from tuberculosis are (1) those intentionally directed as specific measures against the distribution of the tubercle bacillus from the diseased to the well, (2) those that are accessory and tend to affect the general bodily resistance of those particularly exposed or susceptible or are intended to inform the public so that intelligent self protection may become more general, and (3) those events, social economic and so far as the antituberculosis campaign is concerned, quite accidental, in which we may see an unsought unplanned and, to many, an unexpected bearing on tuberculosis The specific measures mentioned are (1) Early and accurate diagnosis of all forms of tuberculosis and especially of the pulmonary form at special public dispensaries as well as by the private practitioner of medicine (2) Bacteriologic diagnosis of specimens of sputum for those suspected of having pulmonary tuberculosis (3) Notification of tuberculosis as a communicable disease to the officers of public health (4) Segregation in a manner to diminish if not wholly to prevent the distribution of the tubercle bacillus from those with 'positive sputum to others, during the active or open carrier stages of the disease This includes sanatorium treatment or its equivalent under skilled medical and nursing direction of those in the active stages of the disease whether showing positive sputum' or not to abbreviate periods of activity or relapse, and to accomplish early and more nearly permanent arrest of the disease (5) Home nursing services for the education of families in which one or more cases of tuberculosis are under the care of a private physician or dispensary so that the resistance of the members of the family may be raised to and maintained at a level which will reduce the probability of development of active stages of the disease and that the infectious discharges of the patient in the form of sputum spray and saliva and in eating and toilet articles often used in common, may be promptly destroyed or rendered innocuous (6) Enforcement of laws and ordinances designed to reduce the habit of spitting in public places where the opportunities are great for the fouling of shoes clothing and articles of common use by discharges from the respiratory tract (7) Enforcement of laws and ordinances forbidding the common use of such articles as drinking cups, eating utensils, towels, etc (8) The compulsory pasteurization of milk and milk products, except such as come from herds or cows proved to be free from tuberculosis (9) Exclusion of parts or all of the carcasses of animals slaughtered for food purposes in which gross tuberculous lesions are found before or after slaughtering (10) Examination and exclusion of those found to be suffering from active or open tuberculosis from industries concerned with the handling and serving of food (11) The control of flies, especially in homes and in hospitals or sanatoria where active open cases of tuberculosis are under care, and where food is prepared or served

*Itchy Points N Toomey St Louis.—p 744
*Radium in Treatment of Subungual Verrucae S Ayres Jr Los Angeles.—p 748
Verruca Plana Juvenilis J B de Medina Madrid Spain.—p 750

Trichophyton Purpureum —After examination of the literature together with the mycologic investigations of his own material Ota arrived at the conclusion that *Trichophyton purpureum* (Bang) *Epidermophyton rubrum* (Castellani) *Trichophyton* A (Hodges) and probably also *Trichophyton rubidum* (Priestley) are one and the same organism, and as it has the character of an ectothrix, it would be more apt to call it *Trichophyton* than *Epidermophyton*

Neurorecurrences After Arsphenamin Therapy —Thirty-nine neurorecurrences are tabulated by Zimmermann Their symptomatology genesis and prognosis are discussed Pathologically there are two types a diffuse meningovascular process and a process limited to one or more focalized lesions In the former the spinal fluid is always abnormal in the latter it may show marked abnormalities or may be entirely normal Prophylaxis of such lesions depends on a thorough mercurial treatment It seems immaterial whether mercury is administered during or immediately following a course of arsphenamin

Quantitative Precipitation Reaction for Syphilis —Kahn adds to his previous discussion of his precipitation reaction for syphilis in which strongly reacting serums showed pre-

cipitation within several minutes and weak ones at the end of three hours' incubation in the water bath He records further observations regarding (1) the preparation of antigen, (2) the dilution of antigen for the tests, (3) the preparation of serum for the tests, (4) the optimum quantities of serum and antigen to be used in the tests, (5) the temperature and time of incubation, and (6) the reading of results

Itchy Points—An itchy disorder is described by Toomey which has characteristics so unique and notable that the diagnosis may be made simply by close clinical observation The disease, or type of itching, is very rare It has probably been confused most often with tic and psychotic (neurotic) scratching The clinical course of the disorder presents features that are peculiar not only in the distribution and character of itching but also in the local appearance of the itchy points The appearance of the skin over a pruritic point, if it has not been manipulated, shows absolutely no recognizable change from the normal If the skin has been scratched or titillated, there will be the usual response to mechanical irritation Repeated fingering of the itchy points may lead to a secondary infection of one or more of the follicles The itching has characteristic limitations It is essentially composed of one or more points, each of which seems to be more minute than the point of a steel pin If two or several itchy points coexist, they are never grouped or even located close to one another The disturbance of sensation is not a burning or stinging feeling but is a tantalizing itching of the severe tickling variety The itching is not continuously present Nor is it always worse at any certain time of the day or night The itchy points favor certain areas A factor common to these areas is the presence of a bony prominence under the skin The cause and mechanism of this type of itching are completely unknown Local applications are useless From the little that is known of this disorder, it is not possible to form any principles of prognosis or direct medication

Radium for Subungual Warts — Strikingly satisfactory results were obtained by Ayres in two cases by the use of radium

Boston Medical and Surgical Journal

Treatment of Diabetes Mellitus E P Joslin Boston —p 833

Treatment of Diabetes Mellitus—Joslin urges that centers of instruction for diabetic patients should be promoted These may form around an individual doctor or a group of doctors or a hospital, but the necessity of such centers is the detailed nature of the instructions which diabetic patients must receive and the expense of the laboratory tests It is easier to teach a group of patients and far less time consuming than to teach individual patients The time required to perform ten tests for sugar in the urine exceeds by little that required for one test When it comes to blood sugar estimations the difference in expense between performing ten tests and one is almost negligible Wholesale methods must be introduced into medical practice to reduce expense and render these tests available for all Private laboratories should be encouraged wherever they exist, and hospitals, whether private or public should extend the facilities of their laboratories to physicians in needs of the same Physicians must learn to cooperate in their laboratory work just as surgeons have learned to cooperate in their surgical work Very few surgeons have their own anesthetists, very few physicians should have their own laboratories The latest and newest methods of treatment are being constantly demanded by patients If the physicians are not able to furnish the results of these methods and tests at suitable fees then the laity will demand that the state furnish them *just as it furnishes* diphtheria antitoxin and Wassermann tests Nurses who are trained in diabetic treatment are of the greatest assistance to physicians This will never be appreciated unless tried For patients, too, who can afford it the simplest way to carry out treatment is to have the diet arranged by a nurse Severe cases are incomparably better treated in this manner than by remaining in a hospital

*Experimental Plethora in Dogs and Rabbits E B Krumbhaar and A Chanutin Philadelphia —p 847

Culture of Bacterium Pneumosintes from Influenza—After artificial cultivation for a period of more than three years, *Bacterium pneumosintes* has maintained its original morphologic and cultural characteristics, when grown in the original medium Adaptation to a saprophytic existence has been accompanied by a loss of pathogenicity The strains used by Olitsky and Gates now grow readily under strictly anaerobic conditions in a variety of mediums with peptone broth as a base enriched with fresh tissue blood, or by the growth of other bacteria Surface colonies have been obtained on blood agar plates in an anaerobic jar These various methods of cultivation are adapted to special purposes In broth cultures *B pneumosintes* grows in larger forms than in the ascitic fluid-tissue medium but the identity of the micro-organisms is proved by their serologic reactions and by reversion to the minute forms on transfer to the

original medium These methods of cultivation are being used in studies of the nasopharyngeal secretions of influenza patients obtained during the present recurrence of influenza in New York City

Experimental Plethora.—The effects of repeated transfusions of blood on the blood-destroying and blood-forming apparatus of normal and splenectomized dogs and rabbits are described by Krumbhaar and Chanutin An anemia which developed despite continued blood transfusions in two dogs splenectomized during plethora was also studied

Bronchoscopic Cases of Dental Origin—Forbes cites five cases in which the foreign body aspirated into the bronchi was of dental origin, as Gold crown in right main bronchus, tooth plate in left primary bronchus, lung abscess from root and small pieces of tooth inhaled, and amalgam fillings loosened during tooth extractions and aspirated while under the anesthetic

Pneumoperitoneum as Diagnostic Aid in Cardiospasm—Judging from the experience gained in a case cited, Iglauer believes that pneumoperitoneum should be of considerable value in the study of obscure cases of cardiospasm From the evidence offered by pneumoperitoneum it seemed likely that the symptoms of cardiospasm in his case were due to adhesions between the diaphragm and the liver encroaching on the subdiaphragmatic esophagus

Biliary Passages Seat of Focal Infection—The importance of the gallbladder and bile ducts as the site of a focal infection is strongly emphasized by McCaskey who agrees with Friedenwald that a search for focal infection cannot be considered complete without a study of the bile obtained by nonsurgical drainage of the biliary apparatus The clinical method of obtaining the biliary secretions for chemical and microscopical study is beset with difficulties which may be slight or insurmountable In about 5 per cent of the patients, McCaskey entirely failed to get the tube into the duodenum on the first trial In some of them he subsequently succeeded The time required varied from half an hour to three hours, and in a few extreme cases to several hours He uses the fluoroscope constantly to determine when the tube is in proper position By revealing the curves which the tube makes, the fluoroscope constitutes the most positive demonstration of the location of the tube In approximately 70 per cent of observations a dark colored, or B, bile was obtained by either an abrupt or gradual transition In the remaining 30 per cent it rarely ever happened that the light yellow bile underwent no changes excepting in those cases in which the gallbladder had been removed or there was good reason to suspect that it was not functioning because of obstructed ducts or other causes Both the gradual transition and the slighter grades of darkening, in McCaskey's opinion are probably due to a slow extrusion of bile from the gallbladder With regard to the cases showing sudden transitions there is no reasonable doubt

Effect of Weight Reduction on Blood Pressure —Weight reduction through dietetic adjustment Rose asserts causes improvement in several important symptoms either due to or associated with obesity One of the most uniformly noticed and the most important of these is the reduction of blood pressure The amount of this reduction is much greater than could be obtained by the use of drugs Excepting Bright's disease focal infection and incurable diseases this method gives promise of being a therapeutic measure which can be relied on to reduce blood pressure Cases amenable to this method of treatment maintain the low blood pressure if the diet is normalized at the conclusion of the reduction Symptoms which seem to be dependent on the increased blood pressure are relieved as the blood pressure falls These are shortness of breath palpitation, edema of the lower extremities and albuminuria One of the worst forms of headache is due to high blood pressure It is very successfully relieved by this method of treatment.

Syphilis of Aorta—As a result of observations it is the judgment of McGavran and Scott that the time to look for syphilis of the heart is when syphilis is first recognized as syphilis and the patient is known to be syphilitic From that time on watch for it as one would for a beginning endocarditis in a case of rheumatic fever

Right Aortic Arch—The specimen of the right aortic arch described by Brigham is the first one observed in the anatomical laboratory of the University of Michigan during the dissection of about 1 400 cadavers, a fact showing the relative infrequency of incidence The specimen was found in a male subject about 50 years of age The heart was normal, and it occupied the normal position in the thorax The arch lay anterior and to the right of the trachea and oesophagus The branches of the arch were a reversal of the normal, namely, a left innominate, which gave origin to the left subclavian and the left common carotid On the right side the right subclavian and the right common carotid were given off This reversal was not accompanied by the transposition of any other organ of the body The arch did not rise high above the heart as is sometimes the case The descending aorta crossed the midsagittal plain obliquely to the left side *before passing through the diaphragm The fibrous remains* of the left arch were about four centimeters in length It extended from the left subclavian artery to the descending aorta and passed downward and backward to the left of the trachea, left recurrent laryngeal nerve and esophagus The ligamentum ductus arteriosus was present on the left side about 2 cm below the fibrous remains of the left arch and was about twice its diameter The ductus was about 2 cm in length It united with the descending aorta about five millimeters distal to the attachment of the fibrous remains of the left aortic arch and communicated with the left pulmonary artery The position of the ligamentum ductus arteriosus shows that it was the persistence of the left sixth brachial vessel The left recurrent laryngeal nerve passed around the ductus arteriosus The right recurrent laryngeal nerve passed beneath the arch of the aorta

Pulsus Alternans—Lyons has been impressed by the fact that if blood pressure readings were performed more carefully, bearing in mind the possibility of the presence of pulsus alternans, this symptom would be far more frequently detected by physicians in general practice than it is at present Owing to the fact that many physicians take graphic records only of cases which show an irregular cardiac action the presence of pulsus alternans frequently eludes them, for here the pulse may be regular with little or no acceleration Furthermore, pulsus alternans may be very transient, rendering the taking of graphic records impractical in many instances The careful use of the auscultatory blood pressure method in all cardiorenal cases, especially accompanied by hypertension, will be of great value in detecting this condition

Magnesium Sulphate in Lamblia Intestinalis Infestation—Knighton believes that the intestinal tract may be rid of these parasites by introducing magnesium sulphate solution in fairly large quantities into the duodenum Of course, the solution does not come in contact with those that are adhering to the walls of the gallbladder and are not expelled The remaining parasites multiply rapidly and soon reinfect the duodenum

Lamblia Intestinalis Infestation—Simon reports eight cases and besides recording the many sided clinical aspects presented, he directs attention to the importance of recognizing the infection and to the need of determining the role it might play in the causation of some of the doubtful cases of intestinal disturbances peculiar to the South The eradication of giardia infection once it has become firmly entrenched in the intestinal tract, has proved a signally unsuccessful undertaking *In two cases reported previously by Simon,* duodenal lavage, with Jutte solution, was given a thorough tryout In one case the cysts promptly disappeared from the stools, but control has been lacking in determining the permanence of this effect In the other case the results proved disappointing

Spinal Anesthesia D N Kalyanvala —p 267

Etiology of Malignant Disease and Leukemia—The bacteriologic investigations made by Young and experimental results he believes support the view that malignant disease and the related leukemic phenomena both in the human subject and in the mouse are dependent on an infection of body cells by an organism which in each case, has specific characters Whether the human and mouse organisms are identical and depend for their slightly differing morphologic characters on the difference in the hosts is still undetermined The experiments demonstrate that the human organism is capable of producing proliferative lesions in mice Experimental proof of the relationship of the organism to carcinoma is lacking in the sense that only in a small proportion of cases has a malignant epithelial growth been found in the injected animals The production on the other hand, of a progressive and malignant neoplastic change in mesodermic cells in a large number of injected animals indicates that the mouse organism is capable of producing a true malignant tumor The experiments suggest that in the healthy animal the only tissue that is capable of responding to the stimulus of the organism by proliferating in a malign fashion is the lymphoid tissue which is presumably built up of cells that retain their embryonic power of free division into adult life Earlier Young suggested that human carcinoma is an infection by an organism which passed one phase in the cancer cell This has been followed in the present paper by the complete and convincing demonstration of such an intracellular phase in the experimentally produced malignant phenomena of the mouse Finally, the investigations incidentally provide data in support of the contention that the leukemic phenomena and lymphosarcoma are related to one another in regard to their ultimate etiology, and that these states are, on etiologic grounds, related to ordinary malignant disease

Deficient Secretion in Upper Alimentary Tract—Bennett and Dodds assert that complete absence of gastric hydrochloric acid, and hence of active gastric ferments is frequently encountered in healthy persons A precisely similar phenomenon is frequently seen in dyspeptic subjects The increased rapidity of gastric emptying time in such cases may be the cause of increased hunger contractions, aerophagy and flatulence In rare cases an increased secretion of mucus is seen in such subjects, this is sometimes an indication of true gastritis and may be secondary to a pulmonary or nasopharyngeal infection In other rare cases of achylia there is delayed gastric emptying, in such subjects there is usually marked visceroptosis In a patient proven

to have pancreatic sclerosis, the fall of alveolar carbon dioxid tension, which normally occurs on the passage of food through the pylorus, was absent In patients suffering from pernicious anemia there is, in addition to complete achylia gastrica, a marked diminution in the "pancreatic fall" of alveolar carbon dioxid tension Such patients have clinically been shown frequently to have signs of pancreatic insufficiency Similar pictures of alveolar carbon dioxid tension and achlorhydria have been found in severe secondary anemias and cachectic conditions The authors believe that the achylia of pernicious anemia is secondary to the blood condition At least four types of pictures are given by the laboratory examination of cases of gastric carcinoma A type characteristic of extreme pyloric stenosis, a type characteristic of cachexia, a type with excessive secretion of mucus, a type difficult to distinguish from benign achylia

Nitrous Acid Poisoning—McClure and Heap record the accidental poisoning of six persons by nitrous acid caused by the inadvertent admixture of sodium nitrate with their food The symptoms were the same in all, but varied in degree The first signs of illness appeared between fifteen and thirty minutes after eating The patients at first felt dizzy and "swimmy," with a great "flushing and throbbing" of the head They had difficulty in breathing as if they were being stifled, there was a slight pain in the stomach and a feeling of nausea All but one vomited They all showed a well marked greyish blue color of the face and lips No pain was complained of, there was no diarrhea They all recovered

Complement Fixation in Gonorrhea—In Osmond's opinion, the complement-fixation test in gonorrhea does not seem to have received the recognition it deserves He considers its value in diagnosis at least as great as that of the Wassermann reaction in syphilis The reaction becomes positive earlier in the disease than does the Wassermann in syphilis, and it does not tend to disappear as a result of treatment till some time after the disease is cured A series of 1,000 tests is discussed

Infantile Acute Endocarditis—Skinner's patient was only 4 months old and was brought to him because of an intractable eczema Apart from the skin eruption the child appeared remarkably well The baby was taken to the hospital and put to bed about 5 p m, receiving his first feed at 6 (modified cow's milk taken well with no regurgitation), after which he went to sleep, waking at 2 a m He was again fed, and went to sleep immediately, waking once more at 6, when he was given a third feed Again he went to sleep, and at 8 a m when the day nurse went to dress the eczema, she found the child sleeping and decided to leave him for half an hour, intending to carry out the dressing later, but on returning at 8 30 the baby was dead He had made no cry, and had not even turned over, there was no cyanosis or frothing at the mouth, nothing to suggest a cause of death At the necropsy it was found that all the organs were healthy with the exception of the lungs and heart On the surfaces of both lungs were several bluish marks about the size of a mustard seed which on closer examination proved to be minute subpleural hemorrhages The heart appeared normal in size and color, but on section it was observed that the tricuspid valve was somewhat less smooth than normal, and, perhaps, a little pinker than might have been expected, though the right auricle and pulmonary artery appeared to be perfectly healthy The mitral valve, however, was found to be gravely involved, the free edges and auricular surfaces of the flaps being extensively covered with a growth of soft vegetations, not large, and quite recent being shiny and pink in color and extremely friable The coronary arteries appeared to be patent and there were no congenital defects of any kind present There had been no clinical signs of any pulmonary or cerebral disturbance, nor were there present any pathologic features, such as pulmonary infarcts or thrombosis of cerebral blood vessels to account for such a sudden death The most likely explanation, Skinner states, is the onset of ventricular fibrillation consequent on the presence of an embolus in a coronary artery sufficiently small to have passed beyond the openings

Capillaroscopy—Laubry and Meyer found capillaroscopy interesting in hypertension but were unable to obtain any clinical information from it which could not be determined by other means

Gonococcus Endocarditis—The serodiagnostic test was positive for the gonococcus in the woman of 29 with infectious endocarditis She died about two months after the first symptoms They had followed a painful, acute polyarticular disease supposed to be rheumatism Only 50 instances are on record of endocarditis with gonococci cultivated from the vegetations in the heart Two cases in this compilation are quoted from THE JOURNAL All but 13 were men in the 50 cases The clinical picture in the case reported here included daily attacks of fever of the sepsis-pyemia type, preceded by chills and followed by profuse sweating The only sign of embolism was the punctate purpura In some of the cases on record there were metastatic abscesses in spleen liver kidneys, lungs or joints In other cases the fever was continuous suggesting typhoid, which seemed to be confirmed by the stupor diarrhea and enlargement of the spleen Auscultation in the case reported revealed the murmur of insufficiency, but the palpitations and other functional symptoms were masked by the severe infection and weakness Agglutination of the gonococcus by the serum was the only clue to the nature of the disease before necropsy The gonococcus was cultivated from the blood in some of the cases but only once in four or five tests The sero-agglutination test is the simplest, and the most constant in its findings, by Porges technic He acidifies the culture and boils it and then neutralizes it, after which it can be agglutinated by the patient's serum In this case agglutination occurred at 1 50 but 1 20 is the rule for gonococcus rheumatism etc The serodiagnosis may allow the use of an autovaccine early enough to abort the disease

Treatment of Ptosis—Lyon insists that gymnastic exercises are the only rational treatment for ptosis The exercises should be done standing and reclining, and breathing exercises should be alternated with the others Drawing in the abdominal wall while holding the breath, and relaxing the wall as one breathes deep, is direct exercise for the stomach Among the more useful exercises done while reclining is to make movements with both arms and legs as if swimming, spreading the legs as far apart as possible Swimming and canoeing are the only sports he advises, and these only when the ptosis shows signs of improvement Rubbing and hydrotherapy aid in making the abdominal wall over, as it were, and thus conquering the tendency of the tissues to sag

*Thoracoplasty for Tuberculosis of One Lung R Burnand—p 788
*Treatment of Tabetic Pains Sicard and J Lermoyez—p 797

Tertiary Syphilitic Joint Lesion—The right ankle had long been swollen and painful in the woman of 41, apparently a tuberculous "white swelling" refractory to all treatment for years Finally the Argyll Robertson sign gave the clue to the nature of the osteo arthropathy, and it rapidly retrogressed under treatment for syphilis

Painful Gynecomastia—Laederich's patient was 76 when his mammary glands became much enlarged and painful Under roentgen irradiation conditions returned to clinically normal, but the testicles became tender An abscess developed in one breast after the first roentgen exposure, but the abscess was in the nonexposed breast

Emetin Polyneuritis—Soca's case of fatal polyneuritis followed eighteen days of treatment with a total of 1 05 gm of emetin for dysentery He wrote that he had encountered about thirty cases of toxic action from emetin, and it proved fatal in quite a number Symptoms of toxic action were regularly observed when the dose of 8 cg was repeated several days in succession In this fatal case death occurred with bulbar symptoms [The death of Soca, a leading clinician of Montevideo professor and senator, was recorded in THE JOURNAL, May 13, 1922, p 1471]

Sign of Incipient Pericarditis—Dargein was able to confirm in two cases the change in the second sound at the pulmonary orifice, to which Josserand has called attention as warning of the erethism of the heart as disease is becoming established The sound is described as a ringing, clangorous clapping *(eclatant, clangoreux, vibrant claque)*

Obliterating Thrombo-Angeitis—Gilbert and Coury describe the first case to be published in France of the "nonsyphilitic arteritis obliterans of Jews" The man of 36 is an immoderate smoker but the intense and continuous pains from the vascular affection the suppuration, and several operations in the course of the year had not entailed anemia He has been free from pain since a Lisfranc amputation in August, and the trophic troubles in the hands have retrogressed although the left radial pulse is imperceptible, as also the pulse in the right foot The affection seems to be restricted to Jews from Central Europe

Attenuated Bronzed Diabetes—The special character of Labbe's case was that although the glycosuria could not be reduced below 20 or 30 gm a day and there was cirrhosis of both liver and pancreas yet the condition had persisted for fourteen years before the fatal exacerbation

Thoracoplasty for Pulmonary Tuberculosis—Burnand calls attention to the success in six of seven cases treated by resection of the first ten ribs the resected segments close to the vertebrae and from 3 cm to 15 or 20 cm long The results, he says have been "so satisfactory so rapidly satisfactory, so complete," that he recently sent three more patients to Roux for this thoracoplasty One man of 40 in this group succumbed to septicemia from infection of the wound, but the cavity in the lung had been completely obliterated The operation should be done under regional anesthesia, and any progressing lesion in the other lung, no matter how minute, is an absolute contraindication Burnand knows of an instance of fatal pulmonary edema after the thoracoplasty in a patient with lesions in both lungs He advises the thoracoplasty only when therapeutic pneumothorax is out of the question, but it has certain advantages over the latter On the other hand, it does not allow the functional recuperation of the lung thus treated

Treatment of Tabetic Crises—Sicard and Lermoyez present evidence that the tabetic crisis is brought on by some superposed factor affecting the circulation, a change in temperature or barometer pressure, an error in diet, or abuse of alcohol These seem to induce a kind of vasomotor shock a hemoclastic crisis, and treatment to combat this shock may ward off and cure the pains in tabes Epinephrin is the treatment of choice for this In three patients suffering from tabetic gastric crises, rebellious to subcutaneous injection even of large doses of morphin the intravenous injection of 0 5 mg of epinephrin in 10 c c of physiologic saline was followed in from half an hour to two hours by complete or nearly complete subsidence of the pain The injection can be repeated in a few hours or the next day They even injected up to 1 mg without disturbance Calcium chlorid had been tried without effect in these cases

Conservative Treatment of Dilatation of the Esophagus—Chavannaz and Nard report a case of megaesophagus in a woman of 53 The symptoms had developed after acute bronchitis The patient found that she was suddenly unable to swallow solid food and, later even liquids did not pass into the stomach The Wassermann test was negative, and she seemed healthy otherwise Radioscopy two months after the onset of symptoms revealed stenosis of the cardia and extreme dilatation of the esophagus, which was filled with fluid Esophagoscopy confirmed the spasm of the cardia They applied systematic measures to dilate the cardia, at weekly sittings and immediately witnessed the transformation of the patient. The vomiting ceased and solid food began to pass into the stomach Four months later the woman had gained over 13 kg in weight, and esophagoscopy showed that the esophagus had returned to normal size

Necessity for Reform in the Management and Care of Mental Diseas... H Claude—p 433

Gastric Manifestations of Cholelithiasis—Harvier confirms that the gastralgic form of lithiasis is quite frequent The attacks of pain are transient, but they resemble those of tabes and pancreatitis The paroxysm seems to be an equivalent for liver colic and tenderness in the gallbladder region and along the course of the phrenic nerve may give the clue In other cases the cholelithiasis induces dyspepsia, the clinical picture may resemble that with any functional or organic disease of the stomach or duodenum The remissions characteristic of an active ulcer are common with this gallstone dyspepsia The pains are more likely to develop and be more intense at night than during the day, and they may spread to the right shoulder, and are aggravated by deep breathing stretching the trunk, jars, and fatigue Fat and eggs are liable to bring on an attack, as also the approach of the

menses Hypochlorhydria usually accompanies gallstone dyspepsia of long standing

Edema of the Intestine—The edema of the ascending colon, in Carnot's case, was the result of compression of the superior mesenteric vein by two large gallstones in the common bile duct

May 18 1922 **52**, No 20

*Transmission of Smallpox by Flies H Hunziker and H Reese—p 469
*Spinal Cord Tumors O Veraguth—p 476

Smallpox and Flies—The conditions in a recent epidemic of 43 cases at Basel indicated the possibility that contagion had occurred by means of flies

Spinal Cord Tumors—Veraguth describes the case of a woman of 53 who recovered completely after removal of a subdural neoplasm The special feature of the case is that intercostal neuralgia for eleven years, rebellious to all treatment, disappeared completely after removal of the spinal tumor The neuralgia had evidently been the first sign of trouble, but the tumor was eleven years developing to a size that induced other symptoms In another case a sarcoma required resection of part of the second to the seventh cervical vertebrae The cure was complete ,and the motor function of the spine does not seem to be impaired in the least The upper vertebrae might have been spared, as the tumor was found lower than anticipated The extreme tenderness of the vertebrae above was misleading The woman of 32 had been under treatment for six weeks for supposed severe hysteria before the tumor was suspected In the case first mentioned, a medical authority had insisted to the very last that the symptoms were of purely psychic origin

*Amebic Abscess in Liver O Falzi—p 648
*Peritoneal Urine Reaction S Solieri—p 651
*Indicanuria V Sebastiani—p 653

Emetin in Amebic Abscess in Liver—Falzi reports the complete and permanent cure under emetin alone of an amebic abscess in the liver of a man of 29 No micro organisms could be cultivated from the pus obtained by puncture of the liver, but the ameba was found in the stools, and the history showed recurring dysentery during the preceding six years, with symptoms from the liver He increased 8 kg in weight during the forty-five days of emetin treatment

The Sgambati Peritoneal Urine Reaction—Solieri expatiates on the importance of this reaction as a guide not only for diagnosis and prognosis but also as an indication when and how to operate The reaction was described recently in THE JOURNAL, June 17, 1922, p 1914 This sign may warn of impending perforation in typhoid, as the ulceration approaches the serous membrane, the peritoneum suffers, and gives the Sgambati reaction before perforation has actually occurred The urine should be tested for it every day during the second week and later, as operative intervention is incomparably less dangerous before than after the bowel has perforated

Test for Indicanuria—Sebastiani has found that commercial hydrochloric acid to which 2 per thousand iron filings or iron rust have been added forms a sensitive and reliable test for indican in the urine

The Secondary Rays in Roentgenization—Guarini describes Ghilarducci's many years of experiments with direct radio therapy supplemented by the generating of secondary rays by bismuth taken internally, or by a sheet of lead opposite the source of the rays or by ionophoresis of a silver salt The latter method was successfully applied in a case of cancer of the cheek and nose, published Feb 24 1921 He has been successful also in treating lupus by irradiating from the sound side with a sheet of lead in close contact with the lesion Guarini has been applying this method also and reports a case of lupus of the cheek and lip, of three years' standing, cured by three applications of this combination The rays were applied through the mouth to the inside of the cheek, with a sheet of lead pressed against the patch of lupus outside The success was equally complete in a case of lupus of the hand, and another with a lesion on the ankle He is now applying this Ghilarducci method on a large scale

The Heart Reflexes—Lafranca analyzes the mechanism of the various reflexes affecting the heart in normal and pathologic conditions Among them he mentions the contraction of the myocardium under precordial percussion, while dilatation is observed with percussion of the first dorsal vertebrae

Problems of Diet in the Treatment of Diabetes—Strauss remarks that, valuable as have been the experiences of the war with regard to the effect of undernutrition on certain cases of diabetes, they have changed nothing in the plan of treatment that he had previously worked out for diabetic patients It is more important than ever to study carefully the individual tendency to endogenous acidosis, to discover for each diabetic the kind of diet that best corresponds to his tolerance for carbohydrates and best fits his capacity for the combustion of acetone bodies These seldom run parallel Special tolerance tests must in every case precede the institution of any particular diet For some patients the control of the amount of protein ingested is even more important than the carbohydrate intake Starchy substances that have to be acted upon for some time by the gastro-intestinal juices before they are dissolved are better tolerated than those in more easily digestible form For the same reason, a proper proportion of fat should be taken with the meals as the fat prolongs the stay in the stomach and thus retards absorption of carbohydrates from the intestine Reduction of the protein intake often increases the carbohydrate tolerance For the permanent diet of patients with marked acidosis a practically carbohydrate-free diet is not admissible in most cases According to the severity of the cases there should be a more or less frequent change in the diet, the purpose being at times to combat glycosuria and at other times acidosis In numerous cases he found von Noorden's *Mehlsuppen* (flour soups) of great value He combats severe acidosis and resistant glycosuria with fast days and days of drinking, but no food He does not approve of protracted fasting, as he has seen

in several cases sudden loss of weight and marked weakness resulting therefrom On vegetable days and "beverage" days he uses alcoholics freely, holding that these save on the total calories required, and also keep down the acidosis The fat intake must be reduced in some cases The restriction of fat and the general undernutrition during the war prevented often the development of the typical coma of diabetes, so that more diabetics made progress than in peace times His study of 1,500 cases of diabetes in soldiers during the war showed that a much larger proportion of the moderate cases were favorably influenced by treatment than is the case in civilian practice He ascribes this to the fact that the diabetes was recognized earlier and given thorough treatment more promptly The surgical complications of diabetes were also remarkably rare in these diabetic soldiers

Treatment of Hyperhidrosis—Joseph recommends in hyperhidrosis of the palms, soles and axillae in mild cases, application twice daily of a 5 per cent solution of chromic acid, or of a 1 per cent watery solution of tannic acid or a mixture of tannic acid 40 glycerin 40, and tincture of iodin 20, or of trichloracetic acid 1, balsam of Peru 1, formic acid 3, chloral hydrate 5, and alcohol to make 100 parts For the night he advises a powder consisting of salicylic acid 5 boric acid 10 tartaric acid 10, zinc oxid 40, and talc 40 parts In moderately severe cases he applies twice daily a 4 per cent solution of formaldehyd, which if necessary, he increases to 20 per cent At night the foregoing powders are applied If the formaldehyd proves too strong an irritant the addition of sodium carbonate will lessen the irritation A milder solution is formaldehyd 2 sodium carbonate 2, and water to make 100 parts In very severe cases he has found roentgen irradiation effective but this causes a roughness and dryness of the skin, with slight atrophic changes

*Kindergarten Teacher in Children's Hospital H Benario—p 593

Natural Immunity in Children—Czerny discusses various factors affecting natural immunity in children among others, a diet poor in purin An infant gets along very well on food poor in purin At what age a diet rich in purin must be introduced is still a matter of controversy We observe the highest susceptibility to disease combined with a marked tendency to hyperplasia of the lymphatic tissues in children who subsist for long periods on food poor in purin There are no doubt children who will thrive for years on a diet poor in purin There are also a great many children who need food rich in purin from the time they are 2 years old Research on metabolism shows that not every child is able to extract from primitive forms of food all that his organism needs and that in many cases, we must prescribe proteins fats and carbohydrates in a definite known form, or harm will arise

The Kindergarten Teacher in the Hospital—Hertha Benario emphasizes the need of kindergarten teachers in the children's wards of hospitals more particularly in the surgical and dermatologic wards in order to prevent a retardation in the mental development of children She urges that welfare societies inquire into this need and endeavor to supply the desired instruction

Recent Publications on Social Insurance P Horn—p 671

Friction Between Pleura and Heart—Frey describes three cases of an unusual friction sound accompanying the heart beat traced to inflammation of the left mediastinal pleura from a tuberculous process in the superior lobe of the left lung The friction sound was heard first at the apex but then changed to the base and it was audible only during expiration instead of with inspiration as at first He queries whether this is a general law for pleuropericarditic friction depending on the distention of the lung at the apex during inspiration and at the base, depending on the narrowing of the space during active expiration

Multiple Sclerosis of Endocrine Glands—Hochstetter relates that necropsy confirmed this diagnosis The thyroid testicles and suprarenals showed the most pronounced sclerosis the parathyroids and pituitary were sclerotic and atrophied and the spleen, kidneys liver and lungs were more or less indurated The whole syndrome had developed in six years in the previously robust farmer of 38 The first symptoms had been intense thirst, sleeplessness headache and impotence Chronic bronchitis and emphysema followed At the fourth year pains suggesting polyneuritis, and extreme weakness apathy and emaciation dominated the clinical picture with low blood pressure polydypsia and polyuria, but the urine was free from albumin and sugar Death occurred from heart weakness He regards this "connective tissue diathesis of the glands as a disease *sui generis* The fact that excessive thirst was the first symptom, and that the pituitary showed the most advanced changes suggests that this gland was the first affected No venereal or infectious disease was known in the antecedents and tobacco and liquor had been used only in moderation

Static Electricity in Medicine—Horwitz describes the application of static electricity by electrodes, air baths and sparks as he has found it extremely useful in hundreds of cases of functional nervous disturbances of all kinds neuralgia in the head insomnia neurasthenia, hysteria, and nervous heart and stomach disturbances

Bilirubinemia—Vogel and Zins treat 0.5 c.c. of the blood serum or exudate with twice the volume of 20 per cent trichloracetic acid The precipitate is stirred up with a glass rod and this emulsion is filtered through a folded filter The precipitate left on the filter turns green as it dries the depth of the tint corresponding to the proportion of bilirubin present They say that this is a specific and sensitive test for pathologic bilirubinemia When negative, the tint is yellowish or white

Treatment of Gastric and Duodenal Ulcer—Crämer discusses particularly such points as admit of a different interpretation than is usually found in the textbooks He holds that hyperchlorhydria is not so much the cause as it is the effect of the ulcer Processes similar to gastric ulcers occur in the bladder, in the vagina in the rectum and in the lower portion of the esophagus, where there is no gastric juice, and duodenal ulcer develops in a strongly alkaline medium If hyperacidity prevents the healing of a gastric ulcer, as is so often asserted, how does it happen that so many ulcers heal spontaneously without attracting any attention by their symptoms? We cannot assume that anacidity was present in all such cases If postoperative jejunal ulcer is caused by the gastric juices, why does it occur in scarcely 2 per cent of all gastro-enterostomies? Several years ago, a patient reported that the bismuth suspension that he had taken for roentgenography had helped him very much—that he had had much less pain since then After this observation had been made repeatedly, Crämer concluded that the bismuth suspension, since it filled the whole stomach, opened up the folds of the mucosa and adhered to ulcerous spots and this might be the cause of the improvement Others have observed similar results Since that time he has often prescribed a bismuth suspension breakfast twice a week with improvement or a cure in the case of many old ulcers that he had hitherto treated in vain by other methods As for lavage with gastric ulcer, it is always indicated with motor disturbances or marked gastritis Marked pyloric stenosis together with high-grade stasis of the gastric contents and moderate *vomiting is a strong indication for operation If after four* weeks' medical treatment (rest special diet, daily gastric lavage, Cohnheim's oil treatment) there is no particular improvement the urine does not increase much in quantity, the stasis does not decrease particularly the weight does not increase and the general condition does not improve in such cases surgical intervention should not be delayed Following operation the after-treatment is of the greatest importance Often successful internal treatment is not possible until after an operation

Asthma W Sternberg —p 196

Pathogenesis of Gout—Continuing their research on gout, Gudzent and Keeser recorded the uric acid content and non protein nitrogen in organs from cadavers and organs removed at operations and the organs of fowls They explain how their findings allow deeper insight into the intermediate metabolism of purins

Polychemical Test for Urobilin—Hausmann announces that addition to urine of a 10 per cent or other strong solution of a salt of any heavy metal or organic or morganic acid seems to suspend the action of some force which otherwise impedes extraction of urobilin with chloroform or ethyl acetate No other pigment can be extracted with chloroform in this way except bile pigment and the latter cannot be extracted with chloroform when a 10 per cent solution of copper sulphate has been used On the other hand, it is readily extracted with chloroform from natural urine The amounts used must be large 2 c c of the concentrated solution of the salt or 6 to 8 drops of the concentrated acid for each 20 c c of the urine

Effect on Heart of Strenuous Physical Work—Bruns and Roemer give the results of comprehensive roentgen-ray study of the changes in the size of the heart compared with pulse and blood pressure in man and animals They show that mechanical influences alone cannot explain the changes observed Besides the action on the heart of the waste products generated in the course of strenuous physical exercise we have to reckon with psychic influences The importance of the latter in modifying the size of the heart was abundantly demonstrated in their experiments This factor does not enter into experiments on animals, as the animals are under the influence of an anesthetic or decerebrated

The Immune Biology of Typhoid—Oeller declares that the old conception of typhoid solely from the standpoints of bacteriology and pathologic anatomy must now give way to the newer conception of disease from the standpoint of allergy and vital reactions This standpoint has been reached in tuberculosis but typhoid is much better adapted for study from this standpoint as the whole process—which in tuberculosis may be spread over a lifetime—occurs in typhoid within a few weeks

Function of the Spleen—Weicksel's research on the physiology and pathology of the spleen has confirmed the close connection between it and the liver, the bone marrow

and the lymph glands, and its importance in destruction of the blood and formation of bilirubin

Pathologic Excretion of Amino-Acids in the Urine—Zondren compares the aminoaciduria in thirty-three cases of advanced tuberculosis with the findings in six healthy subjects and eleven with disease of various kinds but sound livers, and a number of cases of other disease or poisoning. All this evidence testifies to the importance of excretion of amino acids as a sign of severe insufficiency of the liver.

The Jugular Venous Pulse—Ohm discusses the conditions in health and disease as the jugular pulse wave is modified by the work and the filling of the heart. He gives twenty-five tracings and fifteen roentgenograms to explain the findings and their mechanism. The pulse wave was studied with a tiny mirror swinging on an axis glued to the skin. A rod was fastened to the center of the axis, the outer end of the rod resting on the vein and transmitting the movements of the vein to the mirror. This study of the jugular pulse throws light on the functional capacity of the heart.

Asthma—Sternberg calls attention to some new standpoints for treating asthma based on the physiology of the respiratory movements and speech movements and the laws of playing on musical instruments. From these he deduces a physiologic mechanotherapy, a pedagogic didactic method which aims to insure the relaxation of the muscles. The inability to relax promptly is the main factor in asthma, in stuttering, etc. The physiologic pause in the respiration—the relaxation period—must be cultivated and lengthened by systematic exercises. He emphasizes that technical skill in playing on an instrument increases as the movements are made without conscious effort of the will. This fact alone he says, shows the absurdity of combating asthma by counting exercises or other devices which fasten the attention on the anomaly.

Rare Human Monster. Rhachipagus Parasiticus. H. Poltheir.—p. 501.
Case of Primary Carcinoma of the Tube. C. Stanca.—p. 508.

The Surgical Era in Gynecology, Neglect of Borderline Subjects—Mayer expresses regret that in recent years, many surgeons seem to overlook the fact that many gynecologic symptoms do not have their origin in a purely gynecologic affection of some organ but on the contrary have their roots in the patient's general condition. The brilliant success of operative gynecology was mainly due to the fact that it is an organ specialty. This is its strength and at the same time this is its weakness. He knows of young women who have had a series of operations from amputation of the portio, the Alexander-Adams, appendectomy and nephropexy to gastro-enterostomy with hysterectomy finally as the dysmenorrhea and vomiting persisted. There is a tendency to overlook general disease sailing under a gynecologic flag.

Record for Septic Abortion—Dietrich gives in detail a blank form that he recommends for recording the results of treatment of septic abortion. He regards the subject as important in view of the increase in the number of cases. If directors of hospitals and also specialists and general practitioners will furnish him with their data he will gladly later undertake their collation. Dietrich is *Oberarzt* in the Universitats Frauenklinik at Gottingen (Germany), where communications may be addressed.

Zentralblatt fur innere Medizin, Leipzig

March 18, 1922, **43**, No. 11

Modification of Iodin Bile Pigment Test. E. Silberstern.—p. 183.

Improved Technic for Test for Bile Pigments in Urine—Silberstern reports that the ordinary iodin test is made more sensitive and reliable if the iodin is dissolved in chloroform or ether instead of in alcohol. He uses 0.5 part of iodin to 76.5 parts of chloroform, shakes up 1 c.c. of this iodin solution with 2 to 4 c.c. of the fluid to be examined and sets it aside. This is more convenient than estimation from the mere line of contact between the fluids. A green tint as compared with the mother solution is the positive response.

*Invagination After Gastro-Enterostomy. S. Lundberg.—p. 423.
*Hematoma in Sheath of Abdominal Rectus Muscle. E. Perman.—p. 434.
Infant Surgery. S. Johansson.—p. 455.
Spontaneous Rupture of Bladder. N. A. Nicolaysen.—p. 507.

Retrograde Invagination After Gastro-Enterostomy—Lundberg compares with the necropsy findings in his case, six cases he has found in the records in which the upper portion of the jejunum had slipped backward inside the efferent loop. The invaginatum in his case was 20 cm. long, and showed signs of gangrene. Pain and vomiting had been the first sign of trouble. The vomit finally contained blood. The woman died the fourth day. The five patients were all cured who were operated on in from eighteen to forty-eight hours, although the intussusception had not been recognized beforehand except in a case in which it was a recurrence.

Hematoma in Sheath of Rectus Muscle—In one of Perman's 11 cases the hematoma was the common professional injury early in cavalry training. In some of the others indirect trauma was known. Fifteen of the total 20 cases he has compiled were in women, all but one over 35. The correct diagnosis was made before the operation only in 6 cases. The severe pain, tenderness, muscular rigidity, nausea and vomiting, the absence of any direct trauma, and the disregard of the patient's statements as to mild pain following lifting, coughing, overexertion—all mislead the diagnosis. The period of mild pain may last for some time before the acute clinical picture develops. One patient was a hemophiliac, one a hard drinker. Torsion of an ovarian cyst had been assumed in 6 cases, appendicitis or ruptured tubal pregnancy in some of the others. A yellowish edema in the subcutaneous tissue was noted in 3 cases. In 5 there was suggillation. In 3 cases the hematoma subsided under conservative measures alone, but evacuation of the hematoma shortened the healing time materially in the others, and infection was never observed in these 20 cases. An abscess developed from the hematoma in a further case in which the lesion had followed a kick from a horse. The article is in English.

Operations on Infants—Johansson's profusely illustrated report (in English) of operations on infants includes 45 for harelip or cleft palate, 2 cases of atresia of the small intestine, neither infant surviving, and 8 cases of recovery after correction of deformity of the rectum and 104 operative cases of inguinal hernia, all but 4 in boys. He believes in operating early for inguinal hernia in an infant. In his total 115 cases, strangulation had occurred already in 16 per cent. There is also the liability to a vicious circle from gastro-enteritis. The only contraindication he admits is a weight less than 3,000 gm. He operates rapidly, his average time was eleven minutes, always under general anesthesia. In 11 cases of septic osteomyelitis, 9 were cured by the intervention.

In the 6 cases of coxitis the cure was realized without resection although 3 were very severe. In one nothing but an extension bandage had been applied. His impression is that an autogenous vaccine tends to shorten the course and limit the big surgical procedures especially with resection of joints. The whole head of the femur was absorbed in one case. All the others healed with only slight functional derangement. These coxitis cases proved very instructive, he says, as they showed that conservative and expectant treatment is justified in infants in many cases in which otherwise, according to prevailing surgical principles, more radical treatment is indicated. His experience with burns teaches the necessity for hospital treatment for burns in children, even slight burns. The prognosis is unfavorable even with burns of slight extent and intensity. All the 6 infants in this

group finally recovered He adds that the weight dropped by 200 to 400 gm in 40 per cent of 98 infants operated on under general anesthesia, but this drop was transient The temperature usually runs up for a day or two, but this is of no consequence Pediatric care is so important for infants that he advises having the surgeon come to the children's clinic for the operation, rather than taking the child to the adult department In a case of purulent pyelonephritis in a 5 months infant, he exposed both kidneys and found them studded with miliary abscesses He drained the pelvis Instances are on record in which a cure was realized by this, but this child died the same day

Spontaneous Rupture of Bladder, Healing Without Operation—Intraperitoneal rupture of the bladder was diagnosed in the man of 47 from the sudden pain, intense desires to urinate and impossibility to void a drop of urine There had been no trauma but there was a history of old syphilis The fluid drawn by catheter the second day resembled a peritoneal effusion, containing only 1 33 per thousand urea while the blood serum fifty hours after the first symptoms, contained 2 21 per cent urea An immediate operation was advised, but this was refused because the condition seemed hopeless, the man apparently moribund The next morning there was some improvement and 600 c c of actual urine was voided It contained 9 per thousand urea, but only 1 per thousand albumin The uremia rapidly declined and the general condition improved to correspond He was discharged in good condition the thirty-third day The man had been under treatment for the last four years for syphilitic atrophy of the optic nerve, his syphilis dating from twenty-three years before and there had been occasional slight urinary disturbance for several years The patient probably would not have survived an operation Over 50 per cent of the operative cases of rupture of the bladder terminate fatally (In German)

Uncontrollable Vomiting of Pregnancy—Brandt says that the treatment of this condition in his service has been so uniformly successful that he regarded it as almost infallible, until two recent fatal cases confirmed anew that there is nothing certain in medicine He keeps the woman in bed, strictly isolated with rectal drip of 2 or 3 liters of saline, and every evening 3 gm of sodium bromid in 100 gm water, by the rectum with absolutely nothing to eat or drink for a few days recording the pulse temperature and amount of urine, and the amount and character of the vomit As long as the urine total kept above 600 to 800 gm and the pulse below 100, he was serene The fetus cannot be incriminated alone for the intoxication, as in one of his 2 fatal cases of uncontrollable vomiting the supposed pregnancy did not exist Only a hydatidiform mole was found in the uterus of the sextipara Cachexia of unknown cause dominated the clinical picture in this case, the interval since the last menstruation had been only two months when first seen, but the debility had been noted before this In another case of uncontrollable vomiting with impairment of vision and mental confusion, gradual improvement followed induced abortion but the woman still has multiple neuritis and a tendency to psychoneurosis, and is still in bed the sixteenth week In a fourth case, the previously healthy woman began to vomit at the third week of pregnancy and systematic treatment was begun the eighth week Her condition did not seem serious, the urine totaled 900 gm but the sixth day the pulse was 120 and two days later 134 The ninth day she became blind, and then the uterus was evacuated She died the next day The abortion had been delayed too long after the warning of the acceleration of the pulse

Acute Hemorrhagic Pancreatitis—Haugseth adds another to the few cases on record of recovery after operative treatment The pancreas felt swollen and hard but all the symptoms from it slowly subsided after removal of the gallbladder, which contained numerous gallstones Drainage tubes down to the pancreas and to the stump of the cystic duct relieved the pain, and gradual recovery followed Small scraps of necrotic tissue were expelled through the pancreas fistula, but the tube could be discarded the fifth week

POSTOPERATIVE LUNG COMPLICATIONS *

ISABELLA C. HERB, M.D.
CHICAGO

Scientific investigation and clinical experience agree in demonstrating that the causes which underlie the production of postoperative lung complications are manifold, and the best means of obviating them is still a desideratum.

Clinical reports indicate that lung complications most frequently follow abdominal operations, especially stomach, gallbladder (upper abdominal) and pelvic work, with carcinoma of the stomach furnishing the largest mortality.

A review of the records of lung complications following operations performed in the Presbyterian Hospital of Chicago was prompted by a desire to establish, if possible, the role which the anesthesia played in their causation.

Does the anesthetic contribute to the result? Does one anesthetic contribute to it more than another? Pathologic reports indicate that the anesthetic stands rather as one member of a group of agents which in general produce a similar clinical picture, nevertheless, the anesthetic should be carefully selected and judiciously administered.

GENERAL CONSIDERATIONS

In dealing with the process of infection through the upper respiratory tract, we have to reckon with the organisms usually inhabiting the mouth, throat and nose (*Staphylococcus albus* and *aureus*, diphtheroids, pneumococci and occasionally influenza bacilli and streptococci), colonizing in the lung epithelium. Conditions that might predispose to or influence such a contingency are general feebleness, especially in the aged, or lack of resistance in the individual, combined with a concentrated ether vapor, which is capable of destroying the protective epithelium, making colonization possible. That ether is likely to produce respiratory complications is questionable, particularly when a good anesthetic ether has been used and properly administered. The dreaded "mucus inundation," so frequently discussed by English authors, is certainly not witnessed in a properly conducted open administration. A too concentrated vapor during induction is responsible for the large majority of such accompaniments. Pulmonary lesions found after experimental etherization [1] can be satisfactorily accounted for by the concentration of the ether vapor. Dresser found that 'the ether vapor within the closed mask sometimes reached a concentration as high as 34 per cent, while 6 or 7 per cent is the strongest concentration which can be inhaled without irritation to the air passages." He regards any concentration of vapor which cannot be inhaled by a conscious patient without coughing as harmful to the lung epithelium. That ether is the only cause of pneumonia following its administration is contrary to clinical observation. The first deep note absolving anesthesia by the ether route as being responsible for all lung complications was sounded when Gottstein's report in 1898 from von Mikulicz' clinic in Breslau showed that lung complications as frequently followed local as general anesthesia. His studies have been verified by more recent investigators.

J. Frederick W. Silk [2] of London protests against the misleading term "ether pneumonia," which is still in vogue with certain writers. From August, 1915, to March, 1919, Silk was employed in visiting the principal war hospitals in the United Kingdom and the sick base at Malta, with a view to superintending and reporting on the administration of anesthetics. A thousand visits were paid to about 200 hospitals. "The complaints of postoperative bronchial and pulmonary troubles were frequent, and, in accordance with traditional teaching were set down offhand to the anesthetic, especially when ether had been used." Silk observed that the complaints came from certain hospitals, and these troubles chiefly occurred in the practice of certain surgeons, and frequently the staffs of other hospitals in the immediate neighborhood were never troubled in this manner. In the work of individual surgeons, Silk was suspicious that an element of simple sepsis had to be considered, as in one hospital a half dozen patients had high temperatures for two or three days after operation before pulmonary symptoms appeared.

Postoperative pneumonia is frequently a lobar pneumonia, due to emboli which have entered the circulation at the site of the operation. The time at which the symptoms develop varies from a few hours to a week or more. They are sudden in their onset with pain in the chest, elevated temperature, cough and quick respiration and pulse. As a rule, constitutional disturbance is not great. Homans reported the consolidation of an entire lobe, following pulmonary infarction. This author says: 'If such instances of obvious embolic infarction occur, may not others unrecognized serve as the origin of pneumonia, abscess or gangrene?' Bibergeil reported a case of lobar pneumonia in which multiple emboli were found in the pulmonary artery. Fractures of the long bones are occasionally

* Chairman's address read before the meeting on anesthesia in the Section on Miscellaneous Topics at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

followed by fat emboli, which produce infarcts of the lungs, the symptoms of which are so similar to pneumonia that it is sometimes difficult to differentiate the two

In addition to the factors already mentioned, others doubtless come into play, such as excessive air limitations during etherization and the adoption of the same posture for a protracted period after operation, so that mucus plugging and hypostatic congestion are favored Aspiration from the mouth or pharynx of foreign substances, both solid and liquid, weak heart action with low blood pressure producing hypostatic congestion, generalized sepsis, cooling of the body surface, diminished lung expansion caused by pain or tight bandages, and morphin, which allays the reflex excitability of the air passages and thereby favors the retention of aspirated material, all contribute their quota to lung complications Undoubtedly many are secondary to some preexisting bronchial or lung affection, the effect of the anesthetic being secondary In thirty-five of the fifty-five cases reported by Armstrong,[3] a septic focus in some part of the body was present before the development of the lung complication

Patients who have painful abdominal wounds refrain from deep breathing and coughing, which favors basic engorgement of the lungs and the retention in the bronchi of blood, septic matter or vomitus which may have passed into the larynx It is quite conceivable that the use of imperfectly cleaned rebreathing bags, tubes and masks may favor the occurrence of lung complications, particularly if the preceding patient had a recent acute mouth, throat or lung infection Postoperative pneumonia may be caused by bacteria or their toxins, carried through the lymph or blood stream after operation on infected tissue, or by exacerbation of preexisting focal infections Lung abscesses following tonsil and adenoid operations are held by some observers to be embolic in their origin, but the aspiration of septic material or fragments of tonsillar tissue directly through the air passages into the alveoli is a much more probable cause

Preventive treatment of respiratory complications following operation is an exceedingly important consideration Aspetic technic and a minimum traumatism of the tissues during operation decrease the possibility of thrombosis and embolism The anesthesia should be as light and short as possible No solid food should be allowed for at least six hours before operation The stomach should be aspirated in emergency operations The mouth and throat should be disinfected as far as possible with a mild wash containing alcohol The head should be turned to the side to allow mucus to escape and prevent the aspiration of vomitus The operating table should be covered by thick, dry pads and the patient by blankets to prevent loss of body heat during the operation and when being conveyed through halls and elevator shafts Vierordt[4] gives eleven calories an hour as the normal elimination of heat by the lungs, and ninety calories by the skin When these figures are contrasted, the necessity of preventing the loss of heat by the skin through radiation, evaporation and conduction is apparent

The side posture during tonsil and adenoid operations is desirable, as it prevents blood from flowing into the trachea and the aspiration of infected tissue into the lungs Respiration should not be hampered by tight bandages or unrelieved pain following abdominal operations, as the normal descent of the diaphragm is inhibited, thereby interfering with pulmonary ventilation, coughing and expectoration In mouth, jaw and throat operations, an early awakening from the anesthetic is desirable, so that a semirecumbent or sitting posture may be assumed, to assist in clearing the bronchi of aspirated blood, pus or tissue

ANALYSIS OF A SERIES OF CASES

In a continuous series of operations performed in the Presbyterian Hospital of Chicago, lung complications occurred in 107 patients, fifty of whom died There were thirty-one females and seventy-six males, and the ages ranged from 5 months to 90 years Twenty-six patients developed pulmonary emboli, twenty-one of whom died, a mortality of more than 80 per cent There were fifteen males and eleven females in this series The ages ranged from 27 to 75 years The time of development was second day one, third day, two, fourth day, three, fifth day, three, sixth day, three, seventh day, four, tenth day, three, twelfth day, two, thirteenth day, one, seventeenth day, one, twenty-first day, one, twenty-fourth day, one, and twenty-eighth day, one The heart findings before operation were negative except in two patients who had mitral murmurs, and one who had a myocarditis The lung findings were all negative except in one patient, who had an old healed tuberculosis One patient, who suffered very severe electric burns about the genitalia and arm, developed two embolic infarctions, one on the fourth and one on the sixth day following the removal of necrotic tissue and skin grafting Another patient developed a thrombophlebitis and lung infarct on the tenth day following a cholecystectomy, and a year later an embolism on the fourth day following the repair of a ventral hernia of several years' duration Both of these patients recovered Three emboli followed thrombophlebitis The operations were herniotomy, five, suprapubic prostatectomy, five, cholecystectomy, one, appendectomy (gangrenous or ruptured), two, hysterectomy, one, ovarian cysts, two, ectopic gestation one, Porro cesarean section, one, panhysterectomy, one, resection of the bladder for carcinoma, one, ruptured uterus, one, osteochondroma of ribs, one, gastrostomy, one, varicose veins, one, carcinoma of the stomach, one, and burns one Ether was administered twelve times, gas-oxygen-ether thirteen times, and a local anesthetic once

Lung Abscess—Only the abscesses which developed after operations performed in the Presbyterian Hospital of Chicago are included in this series There were four cases One developed fourteen days after drainage of an infected gallbladder, one occurred on the thirteenth day after the removal of a ruptured, gangrenous appendix, and two followed tonsillectomies in adults One of the latter patients had a turbinectomy under local anesthesia, followed by a tonsillectomy under gas-oxygen The latter patient was anesthetized with ether, and it was known at the time of operation that she aspirated a fragment of tonsillar tissue The former developed a lung abscess on the fifth day, and the latter on the fourth day after operation The last patient recovered and the other three died a mortality of 75 per cent The lung findings were negative in all before operation One tonsil patient had a systolic blow in the aortic region Two were given ether, one, gas-oxygen-ether, and one, gas-oxygen

Pneumonia—There were seventy-six cases of pneumonia, with forty-eight deaths, a mortality of 63 per cent These figures include eight cases of pneumonia which were really terminal, as they occurred in patients with carcinoma of the esophagus, in whom gastrostomy was made on account of starvation It also includes four cases of pneumonia which followed the extraction of foreign bodies from the bronchi (tacks, screws, bullets, etc) Excluding these twelve, there remain thirty-six, a mortality percentage of 47 3 Twenty-five patients had some form of lung lesion before operation, and seventeen had heart lesions

Stomach—There were 153 operations on the stomach, nine of the patients developed pneumonia The ages ranged from 42 to 75 years, all were men, and with one exception were suffering with carcinoma of the esophagus or inoperable carcinoma of the stomach The time of development of the pneumonia was second day after operation, one, third day, five, fourth day, one, fifth day, one, and seventh day, one There were eight deaths, a mortality rate of 5 2 per cent It is interesting to note that all of these patients were men, and all but one were suffering from carcinoma One patient had a lung complication, and three had heart lesion before operation

Gallbladder and Bile Tracts—There were 1,381 cases in this series, with ten pneumonias The ages ranged from 48 to 72 years There were four women and six men The time of development of pneumonia was second day, one, third day, five, fourth day, one, fifth day, one, twenty-fourth day, one, and forty-eighth day, one There were six deaths, a mortality rate of 0 4 per cent Two patients had heart lesions, and three had lung complications before operation

Appendectomy—There were 1,560 appendectomies, with nine cases of pneumonia All of these patients were males, and the ages ranged from 2 to 44 years All were suffering with gangrenous or ruptured appendixes There were five deaths, a mortality rate of 0 3 per cent One had a heart lesion, and three had lung complications before operation The time of development of pneumonia was at the end of twenty-four hours, two, second day, one, eighth day, two, sixth day, one, eighth day, one, tenth day, one, and eleventh day, one Seven were given ether, one gas-oxygen, and one a local anesthetic and gas-oxygen

Herniotomy—There were 1,872 cases, with nine pneumonias Eight males and one female comprised this series, and the ages ranged from 5 months to 70 years There were five deaths, a mortality of 0 26 per cent One patient had a heart lesion, and three had lung complications before operation An inguinal hernia in a child, aged 5 months, who was in the early stages of pneumonia, became strangulated, which necessitated an immediate operation This was performed under local anesthesia, except a few inhalations of ether during reduction, as it was impossible to replace the intestine on account of the straining Death occurred three days later It is interesting to note that two patients developed delirium tremens concomitant with the pneumonia, and both died The time of development of pneumonia was second day after operation, one, third day, two, fourth day, one, fifth day, two sixth day, two, and eighth day, one Ether was the anesthetic administered to six, gas-oxygen-ether to two, and local anesthesia to one

Prostatectomy—There were 174 prostatectomies, and nine of the patients developed pneumonia following suprapubic prostatectomy The youngest patient in this series was 50, and the oldest, 90 years of age There were eight deaths, a mortality of 4 6 per cent In analyzing the preoperative conditions of these patients, the high mortality percentage is explainable on the ground that a large majority of these men were suffering with sepsis and some pathologic condition of the lungs, as chronic bronchitis or a myocarditis, cardiac insufficiency, and more or less arteriosclerosis either of the coronary arteries or of the general arterial system Nephritis was also an occasional accompaniment, age and general debility were important factors, especially in the hypostatic type of pneumonia, which developed in from one to four weeks after prostatectomy The time of development of pneumonia was second day, three, fourth day, one, tenth day, one, fourteenth day, one, twenty-sixth day, one, thirty-sixth day, one, and end of fourth week, one Ether was administered to three, gas-oxygen-ether, to one, local anesthetic-gas-oxygen to one and gas-oxygen to four One patient with carcinoma of the prostate died from hypostatic pneumonia following a suprapubic cystotomy and the removal of a small piece of tissue for diagnosis One patient with feeble heart tones and almost complete anuria developed double pneumonia four days after operation

Pneumonia developed after other operations as follows Two after tonsil and adenoid operations, one in a boy, aged 10 years, who had chronic bronchitis and asthma A cellulitis of the hand was drained in a diabetic patient under gas, and three days after pneumonia developed concomitant with a large increase in the sugar content One patient developed pneumonia after a low forceps delivery and perineorrhaphy, one followed a normal delivery on the third day, and one on the seventh day after a currettage for an incomplete abortion Bronchopneumonia developed three days after an ileostomy under local anesthesia for ulcerative colitis This patient had crepitant râles before operation, and was in a very weak, emaciated state This was clearly a terminal pneumonia, as was also the pneumonia which occurred thirty-one days after the removal of a carcinoma from the floor of the mouth There was only one instance of pneumonia following kidney operations, which occurred after the removal of a hypernephroma Three followed osteomyelitis, one, a cleft palate, three, foreign bodies in the bronchi, one, fifteen days after the aspiration of a knee in a patient with streptococcus infection, one, after nerve suture, one, after an extensive plastic operation for roentgen-ray burns, psoas abscess, plastic vaginal work, tracheotomy, exploratory laparotomy in which atrophic cirrhosis of the liver was found, tumor of the spinal cord thyroidectomy and cervical rib One case of pneumonia was clearly an aspiration pneumonia, as the patient vomited solid food on the second day after operation, became alarmingly cyanosed, and recovered, and on the following day symptoms of pneumonia developed Attention is called to the observation that twenty-five had lung involvement and seventeen had heart lesions before the pneumonia complication, while, with the exception of two patients who had mitral murmurs and one a myocarditis previous to pulmonary infarctions, the heart and lung findings were negative, and this was also true of the patients who developed lung abscess No effort was made to designate the type of pneumonia, because it could not be done with any degree of certainty, as

many of the records simply stated "pneumonia", furthermore, the time of development in many instances was determined through a study of the temperature sheets

A woman, aged 29, developed acute miliary tuberculosis twenty-four days after a cholecystectomy, under gas-oxygen anesthesia This patient had tuberculosis of both upper lobes of two years' duration

Attention is called to the remarkable record of 12,045 tonsil and adenoid operations, with only four lung complications, two cases of pneumonia and two of lung abscess, also to the fact that about three times as many men developed lung complications as women in the total number of cases cited

TRAINING IN SOCIOLOGY AND PUBLIC HEALTH AN ESSENTIAL IN MEDICAL EDUCATION*

S W WELCH, M D
MONTGOMERY, ALA

Near the home of my birth, where my youth and young manhood were spent, is one of the foothills of the Appalachian chain, which terminates in Alabama

This mountain stands out boldly against the southern sky I have spent hours in my childhood gazing upon it and wondering what was on the other side In after years when, to the music of a pack of foxhounds and the clatter of a good horse's hoofs, I reached its highest point the thing that interested me most on the other side was not the beautiful plains, streams and wooded country but still higher ranges of mountains in the distance, hiding other things

I have recalled those dreams of my boyhood in my recent study of the work of the Council on Medical Education in its efforts since 1902 to elevate the standard of medical education in the United States The history of this splendid work is as fascinating reading as a romance of the Elizabethan age As in my boyhood experience, when high ground was reached, higher ground came into view, and point after point has been scaled until we stand today on a pinnacle of excellence unexcelled by any other country, but there is still higher ground beyond which we must reach

There has been practically no advance in the teaching of preventive medicine in the last quarter of a century Discoveries of methods of administration and methods of prevention have come forward by leaps and bounds, but they have remained to be learned by the physician after he has taken up his life work and not in that important period when he is preparing for it For that reason, habits of medical thought have not been directed along the lines of preventive medicine, but have been confined almost exclusively to the curative side of the science We shall not reach the highest ground ahead of us until we have introduced into our schools of medical education a course of study which will bring the medical student into easy touch with natural laws governing the transmission and prevention of diseases, the methods to be employed by the health administrators in their control, and the part to be played by the medical profession in the accomplishment of this great task

It is important to recognize that modern attempts to solve, or, at least, to reach an approximate solution of fundamental problems, have led in our own day to the development of a number of comparatively new sciences associated with the basic human needs food, shelter, defense and propagation They are still rudimentary in a large degree and practically unstandardized For this reason they are likely to be lumped together in our minds under the general title of "the social sciences," and to receive from us scant consideration or respect Examined closely, are not every one of these embryonic sciences which deal with the major problems of human existence fundamentally a part of medical science?

Who can say that "a knowledge of the living human body and its many complex normal functions and structures" is more important to the prospective physician than a knowledge of the food substances necessary to keep the body going or to bring it to maturity and productiveness?

Who can say that "a training in dispensaries and hospitals where the student can observe patients suffering from all the more common diseases" is more important to the future practitioner of the healing art than would be a training in courts and prison camps or in legislative halls, where he can study human nature in the raw, as it comes to grips with the problems of life?

If "he needs to be educated in regard to the many and varied forms of remedial agents and procedures which are of generally recognized value," is his need for an education in the many and varied forms of preventive work less imperative or less fundamental?

FIVE ESSENTIALS

If we grant, for the sake of the premise, that knowledge of remedial and preventive methods is of equal importance to the medical student, I am suggesting, for consideration, five essentials in the latter field which should be made a part of his medical education

1 He needs to have a sympathetic understanding of the fundamental human problems in relation to the many complexities of modern life, and must become familiar with the trend of the best thinking along social lines

2 He needs to know the place and function of sanitation in relation to the public welfare, the how and when and why of environmental influence on health In other words, he needs to know when and how to make use of the knowledge of sanitary engineering, not necessarily to be himself a sanitary engineer

3 He needs to be well grounded in the control of the communicable diseases and in bacteriology

4 It is imperative that he should have a knowledge of hygiene, especially in its relation to the social and medical sciences which attempt to improve the race by approximating a solution of the basic problems of human existence, that is, the problems associated with the necessity for food, shelter, defense and propagation

5 He needs to have a knowledge of psychology in its relation to conduct, with regard both to individuals and to groups, in order that he may truly educate both individuals and groups in right habits of action, by supplying motives which appeal to them

The Council on Medical Education and Hospitals is recommending to the American Medical Association at this session that the last two years of undergraduate medical study be devoted to the four majors practice

* Chairman's address read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis, May, 1922

of medicine, surgery, obstetrics and public health The colleges will be asked to pay less attention to courses in special branches during the undergraduate term, and devote more time to the education of medical practitioners

I believe that more attention to the subjects outlined in the foregoing paragraphs will equip men to render a service to the individual and the community which will eventually bring the practice of medicine to a level of achievement undreamed of in the past I believe that men who have received such preparation will be ready after their graduation to practice medicine in cooperation with the many and varied agencies for social betterment, with a greater degree of mutual understanding

CONCLUSION

Let me emphasize the belief that the higher ground toward which we are rapidly moving will afford to administrators of public health a steadily enlarging field of usefulness because of the better understanding by the medical profession of the proper relation between the prevention and the cure of disease, and the appreciation by it of the opportunity to take its proper place of leadership in this great movement toward social tranquility and the improvement of the race

---

CLINICAL AND BACTERIOLOGIC STUDY OF ONE THOUSAND CASES OF LOBAR PNEUMONIA

WITH SPECIAL REFERENCE TO THE THERAPEUTIC VALUE OF PNEUMOCOCCUS ANTIBODY SOLUTION PRELIMINARY REPORT *

RUSSELL L CECIL, M D
AND
NILS P LARSEN, M D
NEW YORK

In the fall of 1920, an opportunity arose for conducting an extensive study of lobar pneumonia in the wards of Bellevue Hospital Through the kind cooperation of the directors of the other medical services, all cases of lobar pneumonia admitted to the twelve medical wards were carefully studied from the bacteriologic standpoint with the idea of determining, if possible, the relationship between the exciting agent and the clinical course of the disease The main object of the investigation, however, was to test the therapeutic value of a serum-free solution of pneumococcus antibody [1] This product was first prepared by F M Huntoon,[2] who has described it at some length in a series of recently published articles

The antibody solution is thus prepared by Huntoon

Horses are injected at regular intervals with emulsions of Types I, II and III pneumococci The serum after a number of injections develops protective antibodies To obtain a serum which protects mice against 1 000 000 lethal doses or more of Type I is readily accomplished It is more difficult to obtain as high a protective power for Type II and against Type III a serum can seldom be obtained which protects against more than 100,000 fatal doses

To this serum is added an equal volume of a heavy emulsion of living pneumococci Types I, II and III The mixture is placed at 37 C for one hour or 20 C for twelve hours, and then centrifuged The sediment is washed with salt solution to rid it of horse serum The washed sediment is emulsified in salt solution containing 0.25 per cent sodium bicarbonate and heated to 55 C for from thirty minutes to one hour This causes dissociation of the pneumococcus (antigen) and antibody The mixture is centrifuged, and the supernatant fluid removed, chilled, recentrifuged and finally filtered through a filter candle The final solution, which contains only 0 035 mg of nitrogen per cubic centimeter is in many lots able to protect mice against as many fatal doses of pneumococcus Types I, II and III as the original serum from which it was made

This preparation is therefore a practically serum-free, aqueous solution of specific pneumococcus antibodies It contains protective substances against pneumococcus Types I, II and III equal in amount to potent polyvalent antipneumococcus serum, yet is almost entirely free from the proteins of horse serum It also contains, in addition to antibody, a small amount of pneumococcus protein which may conceivably act in the capacity of a vaccine and thereby induce a certain amount of active immunity

In some experiments which will be published later, the therapeutic value of pneumococcus antibody solution has been tested in experimental pneumococcus pneumonia in monkeys The results of these experiments are in agreement with protection tests on mice The most striking results were observed in experimental pneumococcus Type I pneumonia Following the injection of antibody, pneumococci immediately disappeared from the blood, and the animal made a rapid recovery When antibody was administered to monkeys that had been inoculated with lethal doses of pneumococcus Type II, the results were not so striking A certain number, however, were saved by this mode of treatment In the case of experimental Type III pneumonia no benefit whatever could be obtained by treating the infected monkeys with antibody solution Since the antibody solution displays its highest protective power in mice against pneumococcus Type I, next highest against pneumococcus Type II and least against pneumococcus Type III, it would appear that the beneficial effect induced by its administration is, in large measure, proportional to the amount of protective substance present

CLASSIFICATION OF CASES

An effort was made to determine the type of infection in every case of pneumonia in the series For one reason or another this effort was unsuccessful in some instances, but in the majority of cases (92 per cent) the exciting agent was isolated

The mouse method was used almost exclusively in the examination of sputum Agglutination and precipitation tests were carried out with the mouse exudate and at the same time cultures were made on blood agar plates from both the heart's blood and peritoneum of the mouse Whenever the readings from the mouse exudate indicated pneumococcus Type IV or atypical pneumococcus Type II, colonies were fished from the plates and the pneumococcus was retyped from the broth culture Typings from cultures were also made whenever the mouse exudate gave a doubtful reaction Practically all fatal cases were checked with postmortem cultures

All cases of clinical pneumonia from which a pneumococcus was isolated were included in the series

* Read before the Section on Practice of Medicine at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

* From the Second Medical (Cornell) Division and the Pathological Department of Bellevue Hospital and the Hygienic Laboratory of the U S Public Health Service This study also received financial aid from the Metropolitan Life Insurance Influenza Fund

1 The pneumococcus antibody olution employed in this work was supplied by the Mulford Laboratories

2 Huntoon F M J Immunol 6 117 (March) 1921

Practically all of these were lobar in type Cases with frank consolidation of one or more lobes were also included, even if cultures failed to reveal pneumococci A few cases of *Streptococcus hemolyticus* pneumonia were encountered in which the signs were not absolutely frank but in every other respect the patients presented the picture of a lobar pneumonia They were therefore included in the series

TABLE 1—BACTERIOLOGIC CLASSIFICATION OF ONE THOUSAND CASES OF LOBAR PNEUMONIA

Organism	Number of Cases
Pneumococcus Type I	320
Pneumococcus Type II	150
Pneumococcus Type III	133
Pneumococcus Type IV	231
Streptococcus hemolyticus	52
Streptococcus viridans	22
Bacillus influenzae	3
Bacillus of Friedlander	4
Staphylococcus aureus	2
Unclassified	83
Total	1 000

In Table 1 the 1,000 cases included in the present study have been classified according to the type of micro-organism isolated In cases of mixed infection the pneumococcus has been given the preference, that is if the sputum showed both pneumococcus and streptococcus, the case has been classified as a pneumococcus pneumonia Cases in which pneumococcus was absent and streptococcus was associated with the influenza bacillus have been classified as streptococcus pneumonia It will be seen from this table that out of 1,000 cases studied, 917 could be classified bacteriologically In eighty-three cases either no pathogenic organisms were found in the sputum, or for some reason or other the sputum was not examined

Of the 917 classified cases, 834, or 90 per cent, showed some type of pneumococcus The remaining 10 per cent were mostly streptococcus pneumonias There were three cases in which *Bacillus influenzae* was isolated in pure culture from the sputum, there were four cases of Friedlander bacillus pneumonia, and two cases of *Staphylococcus aureus* pneumonia

TABLE 2—CLASSIFICATION OF EIGHT HUNDRED AND THIRTY FOUR CASES OF PNEUMOCOCCUS PNEUMONIA

	Number of Cases	Incidence per Cent
Pneumococcus Type I	3 0	38 4
Pneumococcus Type II	150	18 0
Pneumococcus Type III	133	15 9
Pneumococcus Type IV	231	27 7
Total	834	

Table 2 shows the incidence of the various types of pneumococcus pneumonia Out of a total of 834 pneumococcus pneumonias, 320, or 38 4 per cent, showed pneumococcus Type I, 150, or 18 per cent, showed pneumococcus Type II, 133, or 15 9 per cent, pneumococcus Type III, 231, or 27 7 per cent, pneumococcus Type IV When these figures are compared with the figures of Dochez and Gillespie,[3] it will be seen that the incidence of Types I, III and IV pneumonia in the present series is slightly higher than theirs, while that of Type II is much lower At the conclusion of the first year of this study, the incidence of Type I pneumonia was 42 per cent of the total pneumococcus group Type I pneumonia is therefore the commonest type of pneumococcus pneumonia, Type III the rarest

Space will not permit a discussion in this paper of streptococcus pneumonia and the other more unusual forms They will be considered in detail in a future article Our interest was centered chiefly in pneumococcus pneumonia, since the agent which we proposed to test therapeutically was directed against this variety

METHOD OF CONDUCTING ANTIBODY EXPERIMENT

In order to determine the therapeutic value of pneumococcus antibody solution, the twelve medical wards of Bellevue Hospital were divided into two groups In six wards, all cases of lobar pneumonia were treated with the antibody solution The other six were used as control wards In these wards, patients with pneumonia received no antibody, but in other respects were treated in practically the same way as the patients receiving antibody It was first determined that no selection of any kind was practiced by the admitting office in assigning patients to the various wards In Bellevue Hospital, new patients are distributed by rotation, without regard to the character or severity of the disease The control seemed, therefore, to be a fair one from every point of view

RESULTS OF TREATMENT WITH ANTIBODY

Antibody treatment was started as soon as the diagnosis of pneumonia was made The solution was given intravenously in most cases, the technic being similar to that of serum administration The dose was from 50 to 100 c c given once, sometimes twice, occasionally three times a day

The reactions produced by this solution have been one of the most striking features of the study, and deserve especial attention The typical reaction may be thus described There is no immediate reaction From twenty to forty minutes after the injection the patient begins to shiver and is soon in the midst of a hard chill The cyanosis and dyspnea become more marked, and the patient often shows extreme anxiety The chill lasts from fifteen to thirty minutes At its conclusion, the patient complains of fever, and the temperature may have risen to 106 F or even to 108 or 109 In rare cases, the temperature may rise to 110 In one case, the rectal temperature was too high to be recorded on the thermometer When the thermometer was removed, the bulb was missing, and a careful reading of the mercury column recorded 113 1 The patient was wildly delirious during this period of hyperpyrexia, but ice packs were followed by a rapid drop, and on the next morning he showed a normal temperature and made an uncomplicated recovery

In a certain number of cases, morphin and atropin have been administered subcutaneously one-half hour before the injection of antibody, with the hope that such a procedure would mitigate the severity of the reactions In general, it may be said that the reaction was somewhat less intense after morphin and atropin, but the effect was not striking An effort was also made to determine what relationship existed between the severity of the reaction and quantity of antibody injected In our experience, the reaction is not directly proportional to the antibody dosage Ten or fifteen cubic centimeters of antibody have in some cases produced sharp reactions, while in other cases 100 or even 200 c c has excited no reaction whatever As a rule,

3 Dochez A R and Gillespie L J A Biologic Classification of Pneumococci by Means of Immunity Reactions J A M A 61 727 (Sept 6) 1913

however, the reactions are somewhat more severe and last longer when large doses are administered

The high temperature usually persists for only a short time from thirty to sixty minutes The rapid fall is accompanied by a profuse perspiration, which often drenches the patient's linen, and which may continue for several hours The fall may be slight but is usually extensive, often reaching normal or even subnormal limits It may be temporary or permanent It is more likely to be temporary if treatment is started early permanent if the injection is given when the crisis is about due In some cases, however, one or two injections appear to abort the infection completely, and the temperature remains normal on the third or fourth day of the disease

These reactions have every appearance of the so-called 'foreign protein reaction" They usually follow each injection of antibody, but tend to become somewhat less severe with each paroxysm

In three cases, the reaction following injection with antibody appeared to be the immediate cause of death In these three patients, the symptoms were very severe chill, followed by high fever (from 106 to 109), delirium, cyanosis, dyspnea, rapid weak pulse, diaphoresis, congestion of lungs, coma and death In two of these cases death was apparently due to cardiac failure In the third case a long continued hyperpyrexia was probably responsible for the fatal termination

TABLE 3—COMPARISON OF DEATH RATE IN TREATED AND CONTROL SERIES

	Antibody Wards			Control Wards		
Type	Cases	Deaths	Rate %	Cases	Deaths	Rate %
Pneumococcus I	158	21	13 3	162	36	22 2
Pneumococcus II	83	23	27 7	67	27	40 3
Pneumococcus III	73	29	39 7	60	24	40 0
Pneumococcus IV	110	18	16 4	121	29	24 0
Total	424	91	21 4	410	116	28 3
Streptococcus etc	48	24	50 0	35	12	34 3
Unclassified	36	14	38 8	47	20	42 5

Treatment with antibody was usually continued until the temperature of the patient came down and remained below 100 permanently Occasionally, one injection was sufficient More frequently, from three to six injections were necessary The average number of injections was 3 6 for each patient, and the total amount of antibody administered averaged 225 c c for each patient

The results of the experiment are shown in Table 3 It will be observed that 424 cases of pneumococcus pneumonia occurred in the antibody wards, and 410 in the control wards Nearly all the patients in the antibody wards were treated with this solution, the only exceptions being patients that were convalescent or who showed signs of cardiac failure on admission These exceptions, however, were counted as "treated" in the statistics given below There was considerable difference in the mortality rate for Type I cases, 13 3 per cent for the 158 treated cases, as compared with 22 2 per cent for the 162 untreated cases In the Type II groups the treated cases showed a death rate of only 27 7 per cent, as compared with the control death rate of 40 3 per cent In the Type III series, the percentage of fatalities was practically the same for the two groups, 39 7 per cent for the treated, 40 per cent for the untreated cases Strangely enough, a considerable difference in mortality rate was noted in favor of the treated Type IV group, 16 4 per cent against 24 per cent Altogether, the treated pneumococcus cases showed a death rate of 21 4 per cent, while the control pneumococcus series presented a rate of 28 3 per cent

Streptococcus pneumonia was not benefited in the least by antibody treatment In fact, the death rate was higher for the treated series (50 per cent) than it was for the untreated series (34 3) The number of cases however, in the streptococcus groups is too small to permit of accurate conclusions

In the small group of unclassified cases, the death rate was slightly lower for the "treated" wards (38 8 per cent) than for the control wards (42 5 per cent), but most of the former group did not actually receive antibody

EFFECT OF ANTIBODY ON BLOOD CULTURES

Blood cultures were taken in 110 cases out of the total pneumococcus series Of these, thirty-one cases or 28 per cent, were positive In several cases of pneumococcus Type I pneumonia, the blood became sterile after one administration of antibody In one case of pneumococcus Type I pneumonia with 146 pneumococcus colonies to each cubic centimeter of blood and a complicating meningitis, three administrations of antibody of 100 c c each reduced the number of colonies to fifteen per cubic centimeter of blood, though the meningitis proved fatal In two fatal cases of pneumococcus Type I pneumonia which were treated with antibody, blood cultures taken at the time of death were sterile Postmortem cultures were taken in all but three of the fatal cases of pneumococcus Type I pneumonia With two exceptions, these cultures showed living pneumococci in the lungs in spite of the previous administration of large amounts of antibody In two of the fatal antibody cases, postmortem cultures showed that Type I pneumococcus had been entirely replaced by *Streptococcus hemolyticus*

In fatal cases of pneumococcus Type II pneumonia pneumococci were recovered from the lungs in spite of the previous administration of large amounts of antibody In two of these cases, antibody failed to affect the number of pneumococci in the blood In one case of pneumococcus Type II pneumonia, blood cultures taken before, immediately after and three hours after the administration of 200 c c of antibody did not show any numerical change On the other hand, in one control Type II pneumonia, the count on three successive days was forty-two, thirty and three colonies per cubic centimeter, respectively, and on the fourth day the blood was sterile One week later, however, the patient developed pericarditis and died

In serious Type III and Type IV pneumonias with positive blood cultures, the repeated administration of antibody failed to influence the colony count

CASES ILLUSTRATING EFFECT OF ANTIBODY TREATMENT

The following cases, selected from the series of cases treated with antibody, will serve to illustrate the character of the reactions and the effect of this agent on the course of the disease They have been chosen, not to illustrate the most striking results, but as examples of various types of reactions

CASE 1—J S a man aged 31, with pneumococcus Type I pneumonia of the left lower lobe, at 1 p m on the second day of the disease received 50 c c of pneumococcus antibody intravenously Twenty minutes later, he had a severe chill, and the temperature rose from 102 to 108 (Chart 1) This

sudden rise was followed by a rapid fall to 103, and by the following morning the temperature read 101 A second injection of 50 c c was given on the third day, and was followed by a less severe reaction The temperature remained below 103 on the fourth day, and no antibody was administered On the fifth day a third and final injection of antibody (50 c c) was given This produced a mild reaction which was followed by complete recovery

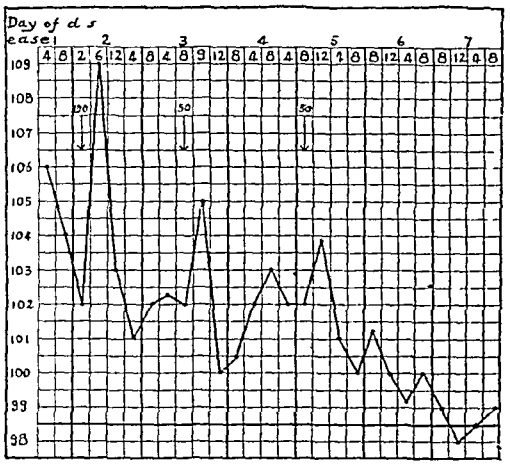

Chart 1 —Temperature in Case 1

This case illustrates well the "stair-step" temperature curve which characterizes many cases of pneumonia treated with antibody The first reaction is severe, and accompanied by a high shoot of temperature With each succeeding injection the reaction is less marked, and the temperature steps down to normal

CASE 2—H D, a boy, aged 15, with pneumococcus Type I pneumonia of the right upper lobe, received the first injection of antibody on the fourth day of the disease Although he received 100 c c intravenously, he showed very little reaction to the antibody, and the temperature did not rise (Chart 2). During that day and the two days following, this patient received in all, eight intravenous injections of antibody seven of 100 c c, the last of 50 c c No reaction of any consequence was noted after any of the injections and the temperature maintained a fairly level plateau Crisis occurred on the seventh day

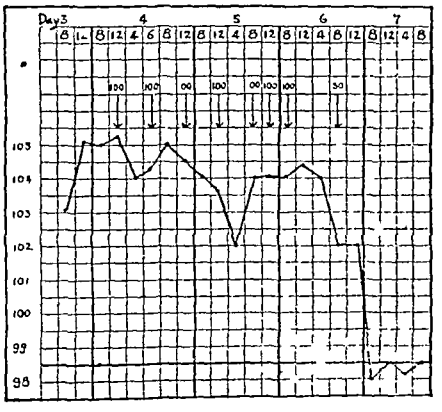

Chart 2 —Temperature in Ca e 2

This case illustrates the comparatively rare type of case in which antibody produces little, if any, reaction The antibody injections induced neither chills nor variations in temperature In this particular case, however, the general condition of the patient appeared to be favorably influenced by the treatment

CASE 3—M R, a man, aged 27, with pneumococcus Type I pneumonia of the right middle and lower, and left lower lobes, received his first injection of antibody on the fourth day of the disease Altogether he received thirteen intravenous injections of 50 c c each Most of these injections were followed by definite reactions, but the temperature never dropped to normal even temporarily (Chart 3) The disease ran a rather long course, with crisis on the eleventh day Ten days later, the patient developed a pneumococcus Type I empyema Thoracotomy and drainage were performed, and the patient eventually recovered

This case exemplifies a group in which antibody is followed by reactions, but in which the temperature does not drop to normal The antibody appeared to exert very little influence on the duration of the disease, though the patient usually appeared more comfortable after the administrations

CASE 4—J P, a man, aged 42, with pneumococcus Type II pneumonia of the right lower lobe, on the third day of the disease received 50 c c of antibody intravenously This was followed by a sharp chill and rise of temperature to 107 4 (Chart 4) During the next few hours the temperature fell rapidly to 100 The following morning, a second injection of 50 c c was given Again the patient reacted with chill and fever of 104 5, and, following this, was free from symptoms

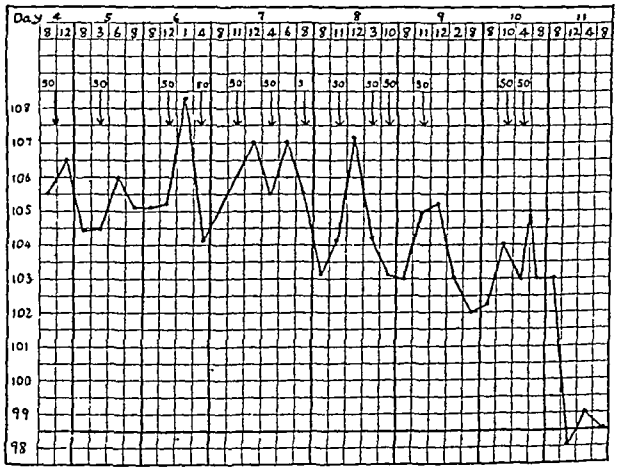

Chart 3 —Temperature in Case 3

This case is a good instance of an abortive pneumonia terminating on the fourth day, a phenomenon so rare with pneumococcus Type II pneumonia that one is disposed to credit antibody for its occurrence

CASE 5—P N, a woman, aged 60 with pneumococcus Type III pneumonia of the right lower lobe, received the first injection of antibody on the third day of the disease She received three injections of 50 c c each on that day, and two injections of 50 c c each on the day following (Chart 5) There was a sharp reaction after the first injection, and there were definite reactions after each of the other four Crisis occurred on the fifth day

This case illustrates a pneumococcus Type III pneumonia that appeared to react favorably to antibody Unfortunately, there were not a great many in this group As pointed out previously, the death rate for Type III pneumonia was not appreciably affected by antibody treatment

CASE 6—F H a man aged 44 alcoholic with pneumococcus Type III pneumonia of the right and left lower lobes received the first injection of antibody on the fifth (or sixth) day of the disease (Chart 6) He received altogether twenty-

eight injections of antibody over a period of eight days The blood culture remained positive, and the patient died of a terminal pneumococcus Type III meningitis

In this case, antibody appeared to have no effect whatever on the course of the disease In spite of huge doses (a total of 1,650 c c) of antibody, pneumococci persisted in the blood stream and the patient died of pneumococcus meningitis

From these examples it will be seen that antibody does not always act in the same way While reactions usually do occur, they may be entirely absent A reaction may follow one injection and be lacking after the next There may be a severe chill or a mild one A rise of temperature may follow an antibody injection, even though the chill did not occur Profuse diaphoresis is sometimes seen without any preceding chill Finally, the antibody may produce a striking effect on the course of the disease, or it may produce no effect whatever In experiments on mice, it is well established that while antibody often protects these animals against 1,000,000 fatal doses of pneumococcus culture, no amount of antibody will protect them if overwhelming doses of culture are injected The same principle probably holds true for man

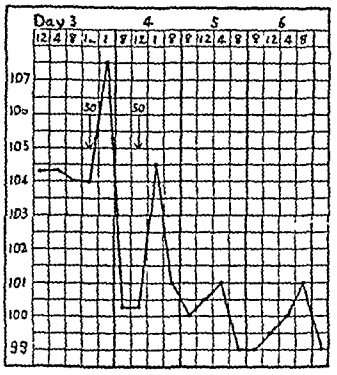

Chart 4 —Temperature in Case 4

No examples of pneumococcus Type IV pneumonia have been included, as the antibody reactions in this group differ in no way from those in the fixed types

EFFECT OF ANTIBODY ON DURATION OF DISEASE

Antibody treatment appears to have shortened the course of the disease in a considerable number of cases In Table 4 it will be noted that in a series of 118 patients treated with antibody on or before the fifth day, thirty-four, or 28 8 per cent , showed normal temperatures on or before the fifth day of the disease, while in 201 control patients admitted on or before the fifth day, only sixteen, or 7 9 per cent , showed a normal

TABLE 4 —DURATION OF PNEUMONIA IN PATIENTS THAT RECOVERED

	Antibody Wards			Control Wards		
	Tot No Tr	T 99	Per Cent	Tot No Adm	T 99	Per Cent
On or before 5th day	118	34	28 8	201	16	7 9
On or before 6th day	143	69	48 2	225	41	18 2
On or before 10th day		91	31 8		118	42 0

temperature on or before the fifth day In a similar way, 48 per cent , or almost half, of the patients admitted on or before the sixth day, had a normal temperature on or before the sixth day of the disease while only 18 2 per cent of the controls reached normal in the same length of time On the other hand, only 31 8 per cent of the treated patients continued to have fever until the tenth day of the disease or thereafter, while 42 per cent of the controls had elevated temperatures for ten days or more

EFFECT OF ANTIBODY ON COMPLICATIONS

Table 5 shows the incidence of complications in the treated and control series In 424 pneumococcus patients admitted to the antibody wards, empyema occurred thirty-one times, with eleven deaths , whereas 410 pneumococcus cases in the control wards were complicated by empyema thirty-two times, with fifteen

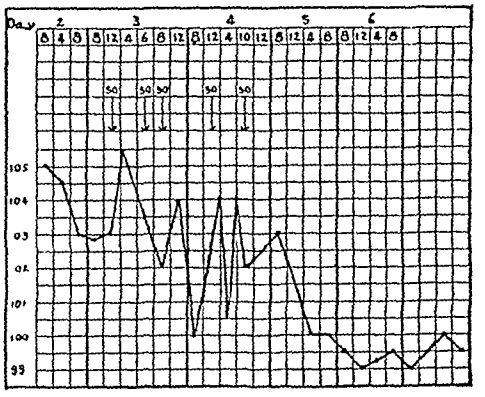

Chart 5 —Temperature in Case 5

deaths Meningitis occurred seven times in the treated series, and eleven times in the untreated Endocarditis or pericarditis was observed six times in the treated

TABLE 5 —INCIDENCE OF COMPLICATIONS IN TREATED AND CONTROL SERIES

	Antibody Ward 424 Pneumonia Cases		Control Wards 410 Pneumonia Cases	
Complications	Total No	Death	Total No	Deaths
Empyema	31	11	32	15
Meningitis	7	7	11	11
Endocarditis pericarditi	6	6	9	9
Arthritis	0	0	2	2
Total	44	24 (54 5)	54	37 (68 5)

cases, and nine times in the untreated cases There were no cases of arthritis in the antibody series, and two cases in the control series Altogether, there were forty-four severe complications in the antibody wards

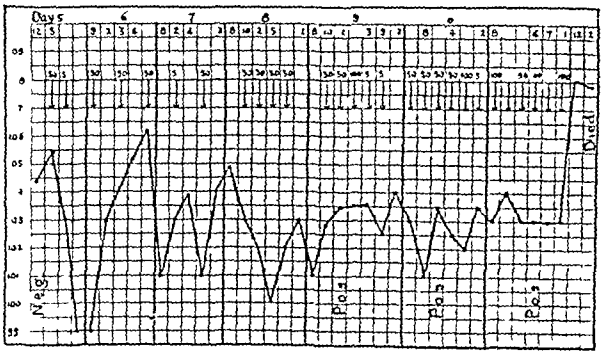

Chart 6 —Temperature in Case 6 *Pos* and *Neg* blood culture positive or negative

with twenty-four deaths (54 5 per cent) and fifty-four severe complications in the control wards, with thirty-seven deaths (68 5 per cent)

From these figures it will be seen that there is no evidence to show that treatment with antibody increases the incidence of empyema or any other severe complication In the case of each of the severe complications

the incidence rate was less for the antibody series than for the control series

RESULTS

From the evidence presented above it may be concluded that pneumococcus antibody solution is a therapeutic agent of considerable power The most striking results are undoubtedly obtained in pneumococcus Type I pneumonia The results in pneumococcus Type II pneumonia are not so impressive, and in pneumococcus Type III cases the antibody solution seems to possess no benefit whatever It would appear from these facts that antibody solution owes its therapeutic value chiefly to the amount of protective substance present Just why a considerable difference in death rate has been observed between the treated and the untreated pneumococcus Type IV pneumonias we are unable to say The beneficial effect of antibody is probably not referable to the shock reactions, otherwise an improvement would be expected in pneumococcus Type III and in streptococcus pneumonia as well as in the other pneumococcus types As a matter of fact, the reactions associated with antibody injections are often very uncomfortable and in certain cases are actually injurious to the patient It has been claimed, of course, that foreign protein reactions have therapeutic value in pneumonia and other infectious diseases There is little evidence, however, in the present study to support such a theory

Patients treated with antibody have never shown any symptoms of serum sickness, and this is a great point in its favor Furthermore, there is no danger of anaphylactic symptoms following the administration of antibody

Perhaps the most important feature of antibody is its polyvalent nature It contains protective substance against the three fixed types of pneumococcus Furthermore, the statistics on Type IV pneumonia indicate that it has some therapeutic value in this type also, probably the result of cross protection In the treatment of 424 pneumococcus pneumonias, the death rate was 21 4 per cent, while, in 410 control cases, the death rate was 28 3 per cent In other words, the figures indicate that in every hundred patients with pneumococcus pneumonia treated there was a saving of seven patients This difference between two almost equal groups of unselected patients, coming from similar environment, during the same seasons, and treated in the same institution, certainly must have some significance

It is possible that considerable benefit could be derived from antibody by administering it subcutaneously In the present study it has been employed in this manner on a number of occasions, and has never produced constitutional reactions Our experience, however, with this form of administration is still too limited to permit of an opinion as to its practical value

SUMMARY

1 In a series of 917 cases of lobar pneumonia in which a definite bacteriologic diagnosis was obtained 90 per cent were of pneumococcus origin The greater part of the remainder were referable to *Streptococcus hemolyticus* or *Streptococcus viridans*

2 In the pneumococcus series, pneumococcus Type I predominated (38 4 per cent) Pneumococcus Type IV was next in frequency (27 7 per cent), pneumococcus Type II (18 per cent), pneumococcus Type III (15 9 per cent)

3 In 424 cases of pneumococcus pneumonia treated with pneumococcus antibody solution, the death rate was 21 4 per cent A control series of 410 cases in the same institution showed a death rate of 28 3 per cent

4 Pneumococcus antibody produces its most striking effect in pneumococcus Type I pneumonia In a series of 156 treated cases the death rate was 13 3 per cent, while a control series of 162 cases showed a death rate of 22 2 per cent A definite but less marked effect was observed in cases of pneumococcus Types II and IV pneumonia which were treated with antibody The antibody solution had no effect whatever on the death rate in pneumococcus Type III pneumonia

5 The death rate of streptococcus pneumonia was not favorably influenced by antibody treatment

6 In the series of patients with pneumococcus pneumonia treated with antibody, 28 8 per cent recovered on or before the fifth day In the control series, only 7 9 per cent recovered on or before the fifth day

7 There were forty-four severe complications in the series of 424 pneumococcus pneumonias treated with antibody, while the control series of 410 pneumococcus pneumonias showed fifty-four severe complications

33 East Sixty-First Street

ABSTRACT OF DISCUSSION

DR F M HUNTOON Glenolden Pa We utilize the principle that antibodies in serum will combine with the bacteria with which the animals were immunized By exposing bacteria to these immune serums, one causes the antibodies to attach themselves to the bacteria Then by heating the sensitized bacteria in an alkaline solution, one can cause the antibody to split off That, in brief, is the method of preparation of these antibody solutions I want to emphasize not only the large number of cases observed but also the adequate control used in this series There is an advantage in the cooperation of institutions for scientific interest Five different institutions had combined resources to gain something of possible scientific value The aim from the start has been to find out whether this material was therapeutically efficient If so, it represented a distinct biologic advance, since we had eliminated the horse serum from consideration The production of serum protein-free solutions has enabled us to do some research on the chemical nature of the antibody An antibody is a definite substance It is not a globulin, and if it is a protein at all it is a peculiar albumin which is not destroyed by alcohol It is not a fatty substance, and it is not injured by trypsin digestion We can say what it is not, but we cannot say what it is

DR NELLIS B FOSTER, New York This antibody extract is being tried experimentally in two institutions in Bellevue Hospital under Dr Cecil, and in the New York Hospital under Dr Connor and myself, both services being parts of the Cornell Medical School In an experiment of this kind it is necessary to have a large amount of data to prove anything at all Last year we had a large number of cases, but at the end of the year we did not feel that we had results that justified making a statement, and at present we do not feel that we have perfect therapeutic measures for treating pneumonia, but we do feel that we are one step farther in developing a substance for treating pneumonia There are statistics on mortality at the New York Hospital for more than a hundred years The mortality has never been lower than 25 per cent During the last two years, it has been materially reduced by the use of this antibody extract, because that is the only material change in treatment during the last two years Still, in the aggregate of several hundred cases of true pneumonia, we do not yet feel certain where we stand Pneumonia is a disease which changes from year to year, and in a city like New York it has a higher mortality than in a rural population

DR WILLARD J STONE Pasadena, Calif I should like to ask Dr Huntoon whether he has reason to believe that the subcutaneous use of this product would be followed by good results

DR. HUNTOON I have no experience to decide the question I know only the laboratory side

DR MARY FREEMAN, Perrine Fla I should like to ask whether there were fatalities from the immediate reaction after the giving of that serum The clinical or medical side is waiting too much for the laboratory I appreciate the work the laboratory is doing, but if physicians will study and heed the symptoms of patients and keep the chest and the back of the arms well covered, remembering the relation of the brachial plexus to the thoracic and other nerves of the chest many a time the giving of an opiate to check the cough will be unnecessary A chill should never be allowed to strike the chest I have the advantage of having a warm climate but, even in Florida after the air cools off it is necessary to warm it In my practice I put a sweater over the nightgown and I apply a hot kaolin poultice For elimination, in my practice I give castor oil and turpentine every day to an adult until resolution sets in If he needs any liver medicine, he gets sodium bicarbonate Atropin is the sheet anchor in pneumonia I start its use in pneumonia before the crisis comes, so that the patient has a blood pressure that will hold him through an ordinarily difficult situation

DR ALEXANDER LAMBERT New York My ward belonged to the control group of which Dr Cecil spoke The feelings of the patient and the result obtained produced an impression even more favorable than the figures show There was, however, a peculiar variation in the different wards Among the controls the percentage varied and the death rate varied from 14 to 64 per cent , but the general totals were exactly as Dr Cecil gave them There has been a great change in the pneumonias in New York City When we had all the alcohol that was desired in life in Bellevue Hospital one third of the 40 000 patients were in the alcoholic wards with or without delirium tremens That made a strong alcoholic group among pneumonia patients and the death rate was 66 per cent. for the alcoholic group and 23 per cent for the nonalcoholic group The type has changed One does not see the thoroughly poisoned chronically soaked alcoholic person in the hospital The change in pneumonia has also been distinct We had two wards of fifty patients each, in one group alcohol was given and the death rate was 40 per cent in the other group alcohol was not given and the death rate was 14 per cent Oddly enough the April pneumonias in New York usually have a higher death rate than do the pneumonias in the winter

DR RUSSELL L CECIL, New York I tried subcutaneous inoculation on some very ill patients to whom I was afraid to give antibody intravenously The results were not striking but I will try it more extensively, and I expect also to try subcutaneous treatment on monkeys In monkeys with experimental pneumonia, our results with antibody treatment were best in pneumococcus Type I cases next best in Type II and worst in Type III As to the fatal reactions If a patient with pneumonia dies within a certain number of hours after an injection of antibody the question naturally arises whether antibody killed the patient In my series there were three deaths probably directly due to the antibody In one case the cause of death was hyperpyrexia In the other two cases the cause was failing circulation As a result of these unfortunate reactions, I have become cautious about giving antibody to older persons or to pneumonia patients late in the disease when they are worn out I have figures based on my series of cases which indicate that the results are much better when the treatment is started early in the disease These patients feel better after the injection of antibody If they have a pain in the side, it usually disappears and they have a general sense of well-being which is quite noticeable The change in the pneumonia death rate of which Dr Lambert spoke is a striking thing In Bellevue Hospital the death rate before prohibition was from 40 to 55 per cent , but the present death rate is only 28 per cent With regard to the leukocyte reactions following antibody injections, I have curves which show a decided leukocytosis which however, is seen shortly after giving the antibody solution, and is only temporary

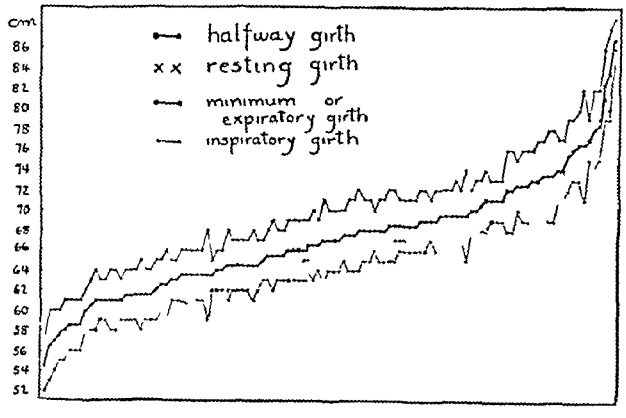
AGAINST MEASURING THE CHEST GIRTH AT REST*

HORACE GRAY M D
BOSTON

Recent biometric evidence that body weight is more closely correlated with chest-girth than with stature [1] brings up anew the ancient questions as to technic

The three levels cannot be entered on here save to state that the axillary has been generally discarded, the mammillary has been used by me in accordance with most medical men, and the xiphoid is very appealing for further study with reference to avoidance of the considerable pectoral muscle and gland tissue in men and women

The moment of the respiratory cycle is the question aroused by the favor accorded by Dreyer [2] to the variously called resting, relaxed, talking, normally breath-



Chest girth nipple level net of 114 private school boys arranged according to size of halfway girth (heavy line) note irregular position of resting girth (indicated by crosses) with relation to minimum or expiratory girth (circles) inspiratory girth light line above

ing and not expanded chest circumference The brief evidence so far presented [3] to indicate the inferiority of the resting girth to the halfway girth (arithmetical mean between the inspiratory and expiratory girths) has seemed to need amplification

The subjects studied composed two normal series one of forty men, the other of 114 private school boys The resting girth was greater than the halfway girth in 18 per cent of the first series of men, equal in 17 per cent and less in 65 per cent , while in the boys' group the respective percentages were 2, 8 and 90 These figures signify that in men generally and in children nearly always the resting girth diverges from the mean girth in the direction of the girth deflated as shown in the accompanying chart

More important is the degree of divergence of the resting girth from the midway girth In the men the average was 0 7 cm , or less than 1 per cent of the mid-

way girth while in the children the error was considerable, 1.3 cm., or about 2 per cent. and reaching 3.5 cm., or 4.2 per cent. of the mean girth.

Furthermore, the actual measurement of the resting girth appears to be associated with a somewhat larger error. The facts are that in ten children, each twice remeasured with fresh application of the tape, the first measurement (i. e., the only measurement ordinarily taken) differed from the average of the three successive measurements by 5.7 per cent. for the resting girth, versus 4.9 per cent. for the mean.

The conclusion is that the chest girth should not be measured at rest, except as a necessity in children who do not breathe freely, as occurs not infrequently under 6 years of age. Measurements are better taken at both full inspiration and complete expiration, and the average used as the midway girth.

THE TREATMENT OF TUBERCULOUS CERVICAL ADENITIS*

RICHARD H. MILLER, M.D.
Surgeon to Outpatients, Massachusetts General Hospital; Instructor in Surgery, Medical School of Harvard University
BOSTON

From the time when Aristotle first mentioned lymphatic vessels, down through the ages to the time when Eustachius discovered the thoracic duct[1] and when, in the time of Edward the Confessor, the power to heal scrofula, or the "king's evil," was ascribed to kings and to the seventh son in a family, through the researches of Sappey in the middle of the nineteenth century—through all these times to the present day—diseases and swellings of the lymphatic system have aroused the keenest interest. Our knowledge is more accurate than it was in the times when scrofula was thought to be due to a faulty mixture of body fluids with an acid substance, called "acrimonia scrophulosa" floating in the blood, or when it was thought by the best authorities to be due to retained semen, and curable by marriage,[2] nevertheless, to this day tuberculosis of the lymph glands is a subject to which every additional bit of knowledge may be of some value.

It is well here to review briefly the anatomy of the lymphatic glands of the neck, and in this I am making use of the valuable work of Wood.[3] These glands form two main groups, the superficial and the deep. The superficial may be divided into the suboccipital, the mastoid or retro-auricular, the parotid, the submaxillary, the facial, the submental, and the retropharyngeal glands. The deep or substernomastoid, from fifteen to thirty in number, extend from below the ear downward, under the muscle, usually to about where the omohyoid crosses. There is a subgroup, under the posterior border of the sternocleidomastoid, called the external. These may extend down as far as the supraclavicular glands. In addition, there are a few superficial glands along the external jugular vein, and two or three inconstant ones on the anterior jugular vein. Lastly is the supraclavicular group, usually considered an auxiliary of the deep glandular chain, but Wood believes that in most cases these do not anastomose with the other cervical glands, and they empty independently into the jugular trunk. This is important in that, if it is true, the supraclavicular glands do not form a line of communication between the mouth and the pharynx and the apex of the lung and do not, therefore, account for the occurrence of apical tuberculosis by direct extension from above. The above mentioned superficial glands, save the supraclavicular, all drain into the deep glands, and the latter into the jugular trunk, which empties into the vein on the right and the thoracic duct on the left. The drainage of the faucial tonsil is important, and, according to Wood,[4] the lymph therefrom passes to one of the uppermost of the deep glands, beneath the anterior border of the sternocleidomastoid just where it is crossed by the posterior belly of the digastric muscle. The pharyngeal tonsil, on the other hand, drains through the retropharyngeal glands directly to the upper of the posterior or external group of the deep cervical chain.

The evidence to support the belief that the tonsil is the main portal of entry for the tubercle bacillus is too voluminous to review in any detail. As a general proposition, it may be stated that about 5 per cent. of all tonsils will show, on microscopic examination, areas of tuberculosis.[5] Weller[6] puts the figure a little lower—2.35 per cent.—and Sir Harold Stiles as high as 9 per cent. Mitchell found tuberculosis of the tonsil in 38 per cent. of 106 adenitis cases without tonsillar symptoms, and Davis[7] notes that he has never seen tuberculous adenitis develop in patients after tonsillectomy had been performed. The pharyngeal tonsil shows tuberculosis even more than the faucial, the figures in 1,671 necropsies being 5 per cent. for the faucial and 10 per cent. for the pharyngeal.[8] Of equal interest is the fact that most cases of advanced phthisis show secondary involvement of the tonsil, Wood's figure being ninety-four cases out of 136, or 69 per cent.

Whether the infection is with the human or bovine bacillus is not of great importance as regards therapy, though it is probably true that in children it is more commonly bovine. Sir Harold Stiles in a large number of cases in children found the bovine type in 90 per cent., and Griffith,[9] in 102 glands examined by inoculation, found that 72.1 per cent. of children under 10 had the bovine type.

The relation between cervical adenitis and pulmonary tuberculosis is interesting. It has been shown that all these cervical lymphatics drain into the jugular trunk, and thence to the right heart and lungs. Should tubercle bacilli break into the circulation in this manner we should expect a miliary tuberculosis, a sequel which, however, is clinically rare. Van Zwaluwenburg and Grabfield, from a large series of roentgen-ray examinations, describe a shadow which they believe to be a thickening of the pleura over the apex, and which is seen in 10 per cent. of all cases, whereas, in those show-

ing tuberculous deposits in the faucial tonsils it is seen in 93 per cent, and in cases with cervical adenitis it occurs in 59 per cent They [10] conclude that tubercle bacilli in the tonsil reach the apex of the lung by a direct line of communication through the cervical glands I do not believe this to be so, and clinical evidence does not, in my opinion, bear it out Wallgren [11] in a careful examination of 516 cases of pulmonary involvement found that this had been preceded by lumps in the neck in only 17 per cent of the cases He was able to follow up 251 cases of tuberculous cervical adenitis and found that the great majority of these patients never developed pulmonary tuberculosis, or if they did, it was mild, furthermore, of twenty-nine patients that had lung involvement with adenitis, twelve were later cured [11] Williams [12] found that in families with an inherited predisposition to tuberculosis, those members who had suppurative tuberculous adenitis did not contract pulmonary tuberculosis, while those who did contract the latter did not have cervical glands

Regarding the treatment, I shall, before considering our own cases, review briefly the most favored and most frequently employed methods The first and most natural therapeutic agent is the sun Heliotherapy has been used in all types of tuberculosis, especially in Europe, where it has been so extensively worked out by Rollier Collected statistics of a large number of cases from the French sanatoriums report 74 per cent of gland tuberculosis cured by sunlight [13] Mayer [14] recommends it highly, and Hyde and Grasso [15] report, as follows, the results in 200 cases of gland tuberculosis treated by sunlight 78 per cent, apparent cure, 11 per cent, arrested, 8 5 per cent, improved, 2 per cent, unimproved, and 0 5 per cent, dead

To be considered at the same time are the various methods of applying artificial sunlight, given under different names, according to differences in the lamps—mercury vapor quartz lamp, carbon arc lamp, etc The carbon arc lamp, as used by Reyn and Ernst in the Finsen Institut at Copenhagen, and the use of which is reviewed in brief by Sauer,[16] furnishes an easy method of applying intensive light, and is apparently to be preferred to the mercury vapor quartz lamp

The use of the roentgen ray has so many supporters that its value may be accepted without argument, though the important question is to decide when to use it and when not, and whether it should always be employed Opinions as to the extent of its value vary a little, some of its advocates asserting that it helps only in some cases while others believe that it is the one therapeutic agent *par excellence* Pfahler [17] believes that is will cure all early cases, and should be used after surgical operation, Berry [18] and Trostler [19] believe that it is the best form of treatment, and Boggs [20] believes that roentgen ray and radium will cure more than 90 per cent of all cases He believes also that radical operation is primarily contraindicated, and in this I gladly concur

Tuberculin, which must be considered briefly, is a solution of certain extracts of the tubercle bacillus, and there are many different kinds, depending on the way in which the extract is made All these different kinds result from attempts of various investigators to procure the substance which will best stimulate the body mechanism to produce a specific antibody By its administration we hope to set up the formation of a defense, which will result in focal stimulation, and the overcoming of the infectious process [21] There are many opponents to this therapy, but if there is any value in it at all we should not discard it Of recent authors, Schmidt [22] Deycke,[23] Crowley,[24] Macrae,[25] Elliott and Sheard,[26] and Abbott [27] believe that tuberculin has an important place in therapy, and the last named says, "Above all other remedies in true tuberculous infections aside from those in which surgical interference is definitely indicated, I give first place to tuberculin" Other observers report no success with tuberculin and it is my belief, from reading the literature, that in bone and joint tuberculosis, at least, it has not in most cases proved of value There is no doubt that tuberculin has been the means of saving many eyes with tuberculous infection,[28] and I have seen several such good results in our own clinic Opponents of tuberculin are many, but its supporters are likewise too numerous to warrant one's saying that there is never any justification for its use. If its action is so beneficial in certain eye lesions, in which it is impossible to use light radiation and surgery, so much the more should we be willing to consider its value in other conditions In our clinic we have also seen many distressing cases of genito-urinary tuberculosis held in check by tuberculin

As we run through the literature we find the advocates of radical surgery decreasing in number, though no one will say that it has not its place Edmunds,[1] Dowd,[29] and Ladd [30] are among the foremost believers in radical operation the last two named referring especially to children Dowd reports 726 patients operated on by himself or his associates with 91 per cent of cures, and Ladd reporting 159 cases, advises early radical operation, with removal of the primary focus Abbott [27] admits that surgery is clearly indicated in some cases but contraindicated if there are palpable glands beyond the reach of the operator, if there is evidence of mediastinal glands, and if there are axillary glands These conditions prevail more often than not in our experience, and fortunate, indeed, is he who gets almost all of his patients at a stage when they are limited to a group which can be easily and quickly dissected out! The difficulties and worries of extensive

radical treatment are well illustrated in a report of Lahey and Chute,[31] reviewing forty-eight cases of the above mentioned procedure Only 43 4 per cent did they class as excellent results, in 26 08 per cent there was paralysis of the spinal accessory, in five cases paralysis of the depressor anguli oris, and in eight cases recurrent glands These patients were operated on by several excellent surgeons, and represent, to our minds, a fair estimate of the results of surgical treatment of unselected difficult cases as they come into a large general hospital The advocates of early operation will say to this that, had they been operated on early, the results would have been better, but in this paper we are concerned with the unselected cases of all types, and more often than not these patients do not come early, and if they do they may not consent to operation, or there may be other contraindications

TREATMENT AT NONPULMONARY TUBERCULOSIS CLINIC

About twelve years ago, there was started at the Massachusetts General Hospital, through the interest and foresight of Dr John B Hawes, a nonpulmonary tuberculosis clinic, the one form of the disease which it was most desired to observe and treat being cervical adenitis, and in which the aim was to treat each patient as a human being and not as a case It was a class rather than a clinic There have been about 600 cervical gland cases, 175 genito-urinary, thirty-five cases of tuberculous eyes, and the rest miscellaneous forms of surgical tuberculosis The procedure is as follows When a patient with cervical adenitis comes to the outpatient department, all routine examinations are made, including those of the lungs, with the roentgen ray if deemed advisable, the throat, scalp, ears and the blood, and in certain cases a biopsy is performed, though we do not believe in the routine removal of specimens for diagnosis The patient then reports to our clinic, where he or she is seen by the internist and surgeon in consultation, and the line of treatment for that particular individual is discussed, and then the patient is referred to the social service department for investigation of home conditions In the majority of cases, the tonsils and adenoids are removed Then, in certain instances, consultation is had with the dermatologist and roentgenologist to consider light or radiotherapy In practically no case, save the acute, red, tender abscess, is any surgical procedure advised at once, though there are exceptions to this rule, notably the chronic solitary cold abscesses, when a gland or group of glands has completely liquefied, and in which we have found that simple drainage is the best procedure, and is usually followed by complete healing in a short while Attempts to dissect out the wall of such an abscess are difficult and not necessary Occasionally there comes a patient with a hard, discrete, easily removable group of glands, in which operation seems, at the outset, advisable, but this is an unusual condition We have, almost as a routine, started them on tuberculin, which, through the kindness of Dr E R Baldwin, we have procured from the Saranac Lake laboratory for the study of tuberculosis After trying this for a few weeks, observing the patient carefully, we then decide whether other therapy should be attempted However, we still put off, for as long as possible, radical surgical interference

To try to form an opinion on the results of our therapy, and to get a broad view of treatment, we took all the completed cases, including those patients that had stopped coming of their own accord, and tried to trace them The number of patients totaled 498, of whom the largest number were between 20 and 30 years of age, the next group being from 10 to 20, and the third those under 10, but owing to the fact that they were mostly nomads by inheritance and in habits, we could get in touch with only 150, in regard to whom certain facts are of interest Fifteen of them had pulmonary infection, of whom only four died after leaving us, though three died of unknown cause Only one developed phthisis after leaving the clinic Of the total number thirty-four had affected glands on both sides, the great majority being limited about equally to the right or left Nine patients had submaxillary tuberculous adenitis, a rather uncommon occurrence More than half had demonstrably infected tonsils and adenoids, which were removed, and with our present feeling many more, if not all, would have been operated on

Half of the patients presented themselves with an acute abscess, requiring incision—this was a secondary infection superimposed on a primary tuberculous condition This type does not well yield itself to radical operation, and here we believe tuberculin to be of benefit With long-standing sinuses the mercury vapor quartz lamp has proved a most valuable adjunct to the other therapy One of our patients with four sinuses on the right side of the neck, without any large glands, and who resisted tuberculin and roentgen ray, was cured after a very few weekly treatments with the Alpine lamp, and a stubborn condition of many months' duration disappeared in an astonishing manner

Our experience with the roentgen ray is too limited to enable me to speak authoritatively on it, but our success has not been striking, in a fair number of cases They were not early ones, but severe cases of long duration, and roentgenotherapy made no marked change for the better in the average patient One striking case, a young woman with a very extensive mass of the whole substernocleidomastoid chain on the right, a tremendous unsightly tumor with subacute inflammation and two sinuses at the upper end, failed to improve in the least under hygiene, roentgen ray and tuberculin, and was sent into the ward for radical operation The inflamed, adherent, discharging mass under the ear was dissected out—such a long tedious process that the operation was not completed, and she was sent out to return for a second operation While waiting for the proper time we continued the tuberculin, and to our astonishment the rest of the glands began to subside so rapidly that from week to week we could observe their shrinkage, and now one can perceive merely a faint scar—this case is one of the most extensive, if not the most so, which we ever had

Of the 150 patients whom we traced, fifteen still are having trouble with persistent glands—all of these were persons that did not follow up the treatment, we neither gave them tuberculin enough to satisfy ourselves, nor did we have a chance to carry out other effective measures As noted above, seven died and one only developed phthisis after coming to us Of the total 150 cases, 127 are classed as cured with excellent results, fifteen as failures due to ceasing treatment, eight as failures to respond to conscientiously applied therapy In 109 of these cured patients the chief therapeutic

31 Lahey and Chute End Results of the Surgical Treatment of Forty Eight Cases of Tuberculous Cervical Adenitis Boston M & S J 186 280 (March 2) 1922

agent besides hygiene, and in some incision of the secondary abscesses, was tuberculin, in twenty-nine of these we believe it to have been the chief element in the cure, and in eighty others we believe it to have been a very great help Four cases of recurrence after radical operation yielded promptly to tuberculin, and another case which recurred after ceasing tuberculin subsided at once on renewal of the specific therapy Three distressing tuberculous eye infections were cured with tuberculin On the other hand there have been a certain number of patients on whom tuberculin exercised no beneficial effect whatever, and these were then treated by operation, by light or by roentgen ray, the desired result thus being achieved The tuberculin employed by us is the tuberculin B F, or bouillon filtrate, the initial dose being one ten-thousandth of a milligram It is given once a week and the dose increased gradually, being reduced slightly in case of too much reaction Some of the patients would receive as much as 100 milligrams, or more, a week Each patient is carefully observed at each visit to the clinic

When other methods have failed or when there seemed some special indication at the outset, we have resorted to radical operation Our prejudice against surgery as a primary procedure is based on the following

First, a majority of the patients can be cured without it, leaving little or no scar

Secondly, the cases as they come to us, unselected, involve as a rule too many glands to promise any cure short of a very extensive dissection, with its accompanying dangers of nerve injury, postanesthetic complications, and unsightly scar

The chief argument for operation, as against other methods, is that it is prompt, and if successful, does away with the necessity of weeks or months of treatment In reply to this it is our contention that the average case as we see it is better in the long run without extensive neck dissection that the dangers of nonoperative treatment are practically nil, and that we can send out patients happier, in the end just as well, and with little or no cicatricial deformity Operation has its place, but that is not the first place in the average case Our clinic is, as I said above, a sort of class—we get to know the patients and they us—we watch over their hygiene and mode of living, as well as treat them specifically

To summarize briefly, a case reporting to us is studied thoroughly and when a diagnosis of tuberculous adenitis is made, we do approximately as indicated below

1 Hygiene and mode of living are investigated, and corrected as indicated

2 The tonsils and adenoids are removed, unless contraindicated

3 Acute abscesses are drained

4 Discrete cold abscesses without acute superimposed infection are opened through a small incision, and drained for a few days with a small rubber tube

5 Patients with chronic discharging sinuses are treated with tuberculin plus the mercury vapor quartz lamp

6 Discrete localized glands are at the outset either removed or treated with tuberculin

7 Extensive disseminated glands, and those showing deep involvement, are treated with tuberculin If this fails we then try roentgen ray, and lastly operation

CONCLUSIONS

There is no certain therapeutic agent, no absolute specific and no set rule for treating tuberculous cervical adenitis To lay down a definite scheme, and treat every case thereby is, in my opinion, not productive of the best results Each patient must be carefully studied and considered as an individual, and then, by the judicious application of our five chief methods, hygiene, light, radiation, surgery and tuberculin, either singly or in combination (for each has its place), we will find that we approach, as nearly as possible in this stubborn and difficult condition, our therapeutic goal

402 Marlborough Street

ABSTRACT OF DISCUSSION

DR HARRY G SLOAN Cleveland Dr Miller has expressed exactly the general feeling in regard to the treatment of tuberculous glands of the neck In the last ten years, this has shown remarkable change The change in point of view has originated principally from the attitude of the roentgenologists Tuberculosis of the glands of the neck must be managed according to the patient's hygienic surroundings The treatment must be adapted to the resources of the patient Under ideal conditions it is most important first to eradicate the focus of local infection In all cases of cervical adenitis we advise routine removal of tonsils and adenoids This is done under local anesthesia when feasible In children general anesthesia is necessary The tuberculous person stands general anesthesia poorly, so we avoid it when possible When the glands are deeply situated, we depend on the roentgen ray We do not advise operation on the glands unless one of them breaks down We then make a small incision parallel to the normal wrinkles of the neck in order to evacuate the contents The general immunity of the patient is increased 20 per cent by rest in bed A man's immunity to any type of infection is probably 20 per cent better in bed than when he is up and around And the patient must be out in the open Recent studies in metabolism during open air treatment showed that the general metabolism is increased from 50 to 60 and even higher Overfeeding is important I like to give cod liver oil In the very resistant cases when immunity is not readily established, we have advised one or two accessory measures such as repeated transfusion of whole blood The last hygienic measure we dispense is open air Practically everybody can sleep outdoors or can arrange his affairs so as to have an outdoor job

DR FRANK H LAHEY Boston Every one who has been through the stage of radical surgery for tuberculous glands of the neck is very glad to see the treatment return to conservative measures The statistics which Dr Miller gave in his paper regarding spinal accessory paralysis are based on a series of twelve cases collected by my associate and me and I wish to emphasize particularly the seriousness of this lesion to which, I believe, due weight has not been given There is a teaching that if the spinal accessory nerve is cut its function will be taken up by the cervical plexus This is based entirely on the assumption that junction of the third and fourth cervical nerves with the spinal accessory which takes place beneath the border of the trapezius occurs It is called the subtrapezius plexus As a matter of fact this junction does not always occur and absolute dependence cannot be placed on the foregoing statement The trapezius muscle is an an all important unit of the shoulder girdle muscles It is practically the only muscle which anchors the scapula and the muscles arising on it to the spine It accomplishes the last 90 degrees of abduction and if its function is lost produces serious crippling of shoulder joint motion In this series of twelve cases of spinal accessory paralysis operations were performed by six surgeons operations of all types from complete block dissections to simple incision of tuberculous abscesses If you have an opportunity to review your cases in which dissection for tuberculous glands of the neck were made, I believe you will be surprised at the num-

ber of cases of spinal accessory paralysis, and the definite crippling and loss of function resulting from it This is, I believe, a serious argument against extensive dissections, except in urgent cases of failure to obtain benefit by the last radical measures It has also been our experience that, even when the spinal accessory nerve has been carefully preserved throughout its course, paralysis may occur later Hence, it must be borne in mind that this lesion is always possible in any case in which extensive dissections are undertaken

DR RICHARD H MILLER Boston Quite a while ago I was given the assignment of tuberculous gland cases at our hospital with the idea that I would operate on all patients, but in examining them, I came to the conclusion that operation was by *no means the first consideration* I found that ordinarily the adenoids and tonsils were not removed unless the nose and throat man could see something definite I believe now that this is wrong, and that in every case, irrespective of what the tonsils and adenoids look like, they should be removed One thing that has helped us in handling these people who live in crowded districts is that we have a social worker who keeps in touch with them The question of using tuberculin is one about which there has been a great deal of argument but surely it has helped us a great deal in many cases If we attempt to treat all cases in this specific way, we shall be disappointed, but it has a very definite place, and we have used it now for nearly twelve years We try it, and if we do not get results we make a change, but there are some results that are perfectly astonishing For example, a man came in with a tremendous tumor of the neck a few years ago We treated it with tuberculin and it got no better until one day the tuberculin created a tremendous reaction The arm swelled to three or four times its normal size and the man was very sick, owing to the unexpected action of the tuberculin However the glands began to diminish in size in the most surprising manner He was given a little more tuberculin and within six months he was accepted for service in the Army No note was made at that time of the glands, so they were at least not visible or palpable on casual examination We must remember that it is a difficult problem one which requires patience If we treat our patients with the best means at our command and encourage them and supervise their home conditions in the end we shall have much better results than we used to achieve with the old radical operation

THE EFFECT OF QUINIDIN ON STRIPED MUSCLE*

J G BRODY, M D
CLEVELAND

The puzzling effect of quinidin on auricular fibrillation renders it advisable to study its actions on the fundamental properties of muscle This can be most conveniently and accurately approached in skeletal muscle Experiments with frog's gastrocnemius or sartorius, immersed in dilute quinidin solutions, show the following variations from the corresponding normal muscle (immersed in unpoisoned Locke's solution)

1 The height of contraction is diminished
2 With tetanizing currents, the peak of contraction is not so well sustained
3 The muscle ceases to respond to any stimulus much sooner than the corresponding unpoisoned muscle
4 Load fatigues it more easily
5 About ten stimulations a second cause a completely fused tetanic contraction in normal muscle, but with the quinidin muscle, the fusion is usually incomplete, no matter how frequent the stimulation and becomes less and less complete the more the muscle is fatigued or loaded
6 The quinidin muscle therefore responds intermittently to a tetanizing current

* From the Pharmacological Laboratory of the Western Reserve Medical School

The contrast is shown in the accompanying illustration, in which the upper tracing represents the complete tetanus of the normal muscle, the second tracing the contractions of the quinidin muscle, the third tracing represents the stimuli, and the lowest tracing, the time, in seconds The muscles were arranged so that the same induced current passed directly through the two muscles

Whereas the normal (upper) muscle shows one contraction throughout the stimulation, the quinidin muscle contracts at an almost regular rate of about fifteen a minute, although the rate of stimulation was about eight a second

Upper tracing complete tetanus of normal muscle second tracing contractions of quinidin muscle third tracing stimuli lowest tracing time in seconds

These effects can be conceived as depression of the muscle, slow recovery of excitability, and consequent failure to respond to rapid stimulation, until the muscle has rested, therefore, intermittent response to frequent stimulations, the rhythm of the contractions depending not on the frequency of the stimulation, but on the rate of recovery of the muscle

In consequence of the rest, the contractions are strengthened

This seems to furnish a plausible explanation of the effect of quinidin on auricular fibrillation

Further work will be needed definitely to establish whether this explanation covers the clinical phenomena, or whether other factors enter into them

Quinidin probably depresses the cardiac muscle, so that it cannot respond to all the numerous stimuli that give rise to fibrillation, but only to a restricted number, thus giving opportunity for periods of rest

The Colonial Exhibition at Marseilles—The *Presse medicale* calls attention to the medical exhibits in the Colonial Exposition which is now open at Marseilles As long ago as 1897 Colonel Lyautey wrote from Madagascar to the French government 'Give me four physicians and I can send back to you four regiments' The medical men have been the pioneers in the French colonies and the extent of their work is now displayed in the exhibits of the public health service in the various colonies the hospitals in charge of scientifically trained natives the medical schools, the utilization of mineral waters, seat bathing, etc, and sanitation of towns "As usual, however,' our exchange remarks, "the prevention of disease in agriculture and stock raising makes by far the most imposing showing Is this due to the indifference of the public powers to human health in comparison to the financial profits? It does not seem so Is it due to the modesty and the timidity of physicians? Possibly"

OBSERVATIONS ON THE IRIS IN HEALTH AND DISEASE AS SEEN WITH THE SLIT LAMP*

ARTHUR J BEDELL, M D
ALBANY, N Y

This communication is based on the result of more than 250 examinations, including iridodialysis, iritis, uveitis, kerato-iritis, iridocyclitis, interstitial keratitis, glaucoma of all forms and cataract of many types The usual routine has been followed with the slit lamp, using binocular 75 and ocular 33 Special studies have been made at greater magnification

To present some new facts and emphasize the importance of this examination, it has seemed best to review part of our present knowledge regarding iris anatomy, and then to discuss embryologic remnants and pathologic changes

An examination of the iris with oblique illumination will materially aid in understanding the usual contour and some of the common color arrangement The microscopic section shows the zone about the pupil, which is usually a dense brown There is a distinct bulge back of this margin which we call the spongy portion of the iris, and the most prominent part of this sponge the shelf I suggest these names only because they are short and more easily remembered than the region of the greater or lesser vascular circle and because, furthermore, the iris under examination gives the impression in many cases of a sponge Where this spongy portion of the iris overlaps there are many variations in the normal eye Definite bands may stand out prominently with depressions between, as caves, hollows or lacunae, or the whole iris may seem like a

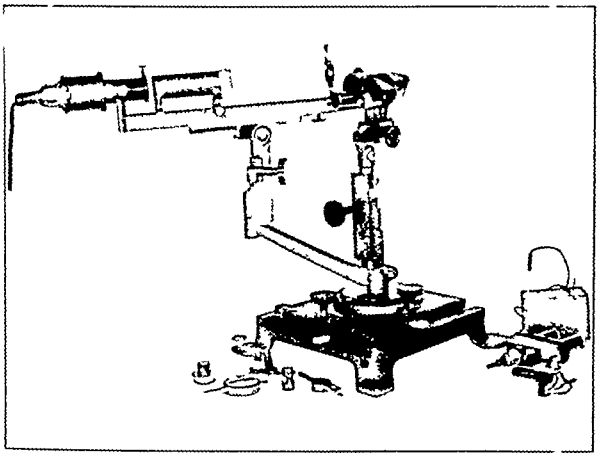

Fig 1—Slit lamp movable base with lamp and microscope attached so that the two may be moved together an arrangement that is of the greatest practical value

fresh water-soaked sponge The individual fibers are well defined in the light colored iris, whereas in the dark brown iris the folds are more often shallower and the hollows less marked

The peripheral part of the iris is frequently arranged in concentric rings and, although they may be absent, we have been able to outline as many as six The radiating folds which are grossly evident vary much in depth and number So far, we have been unable to attach any pathologic significance to them

The blood vessels of the iris are often visible, and in cases of atrophy it is frequently possible to follow them through most of their course They may be markedly increased in number and size, especially in chronic simple glaucoma and in sympathetic ophthalmia The iris nerves are at times easily outlined

The pigment of the iris is of two types, and presents so many variations that, unless a specific plan is followed, there must surely creep into the literature and into the understanding of cases very wrong conclusions The pigment surrounding the pupillary margin is

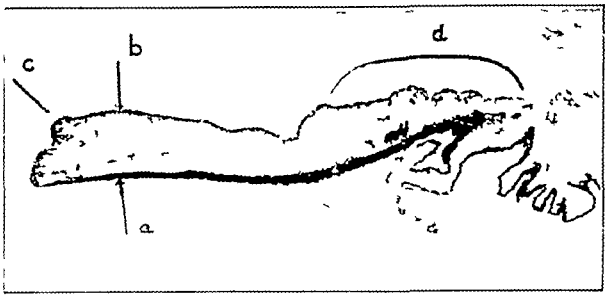

Fig 2—Microscopic section of iris (*a*) retinal pigment (*b*) sponge (*c*) shelf (*d*) concentric folds

retinal, and, as far as I have been able to see, always appears as a dark brown mass This varies in intensity as well as in extent and is often seen as a layer, notably in the iris atrophy of age or the congenital absence, albinism The marginal band may be markedly increased so that in parts it extends over the iris stroma It may be so great that it becomes adherent to the overlying iris, in one case about one fourth of the circumference of the pupil was occupied by a densely pigmented mass, and in another case it was adherent to the iris with four distinct grayish bands of adhesion The same pigment may become pedunculated, or it may even be free on the iris In contrast to the increase, we frequently see by transillumination irregular absorption at the pupillary margin, at other times there is almost complete blanching

The other type of pigmentation, iritic, is that which makes the distinctive color of the eye and is necessarily of endless variety This superficial pigment ranges in color from light yellow to an intense brown, and may be so irregular in distribution that care must be taken to determine whether a given spot is of iritic or retinal origin

Pigment on or in the iris we consider under spots, dots, dashes, granules, specks, balls, thin filamentous veils and densely pigmented layers It may be on the posterior surface of the cornea, in the aqueous or on the anterior capsule of the lens The interpretation of pigmentation will lead to prolonged study So far, we believe that the superficial spots ranging from light yellow to dense brown are normal, that pigment deposits on the capsule of the lens may be embryologic, although if the same pigment, particularly indefinite masses, are about the iris margin, they signify present or past inflammation of the iris, and, if the dense brown masses are vascularized, it is evidence of a severe chronic uveitis If there be irregular granules or specks and dashes on the posterior layer of the cornea and in the aqueous, there is a definite pathologic process, most often glaucoma The thin and dense veils are always indicative of pigment migration, which

* Read before the Section on Ophthalmology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

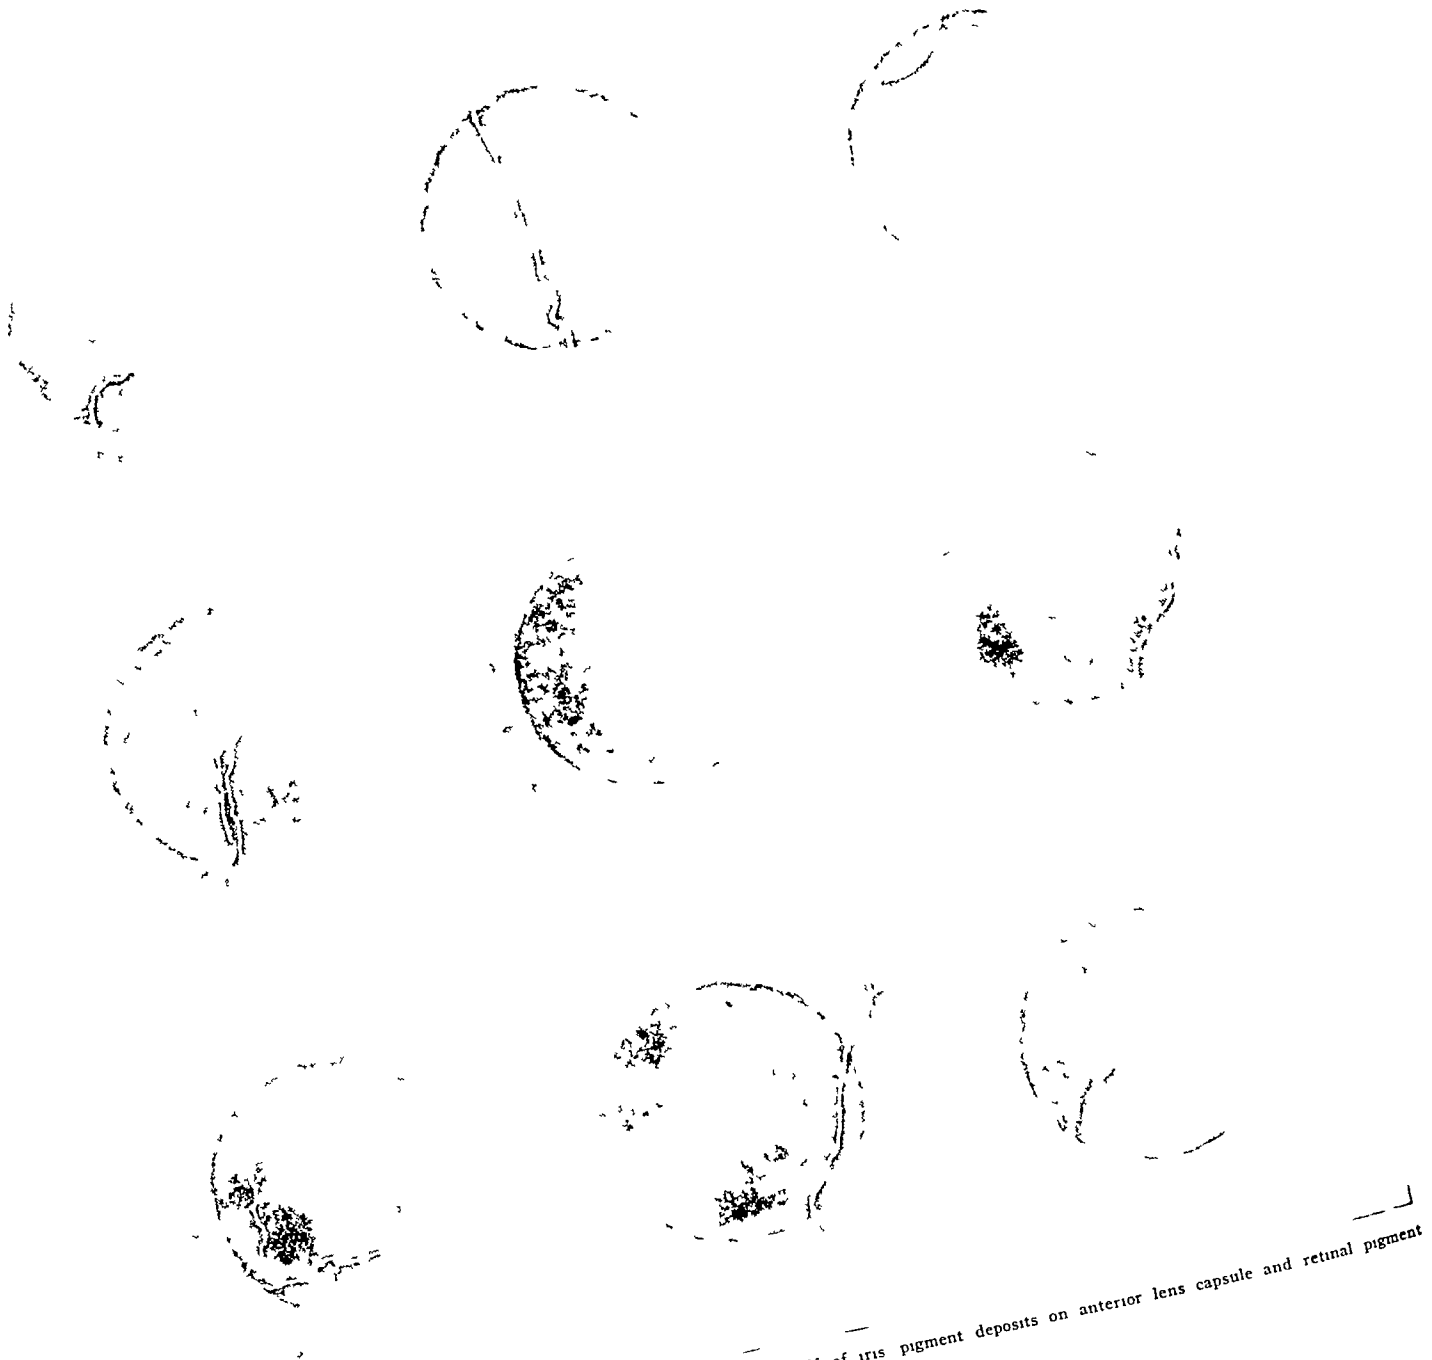

Fig 3—A few of the many embryologic changes filaments from shelf of iris pigment deposits on anterior lens capsule and retinal pigment mass adherent to iris stroma

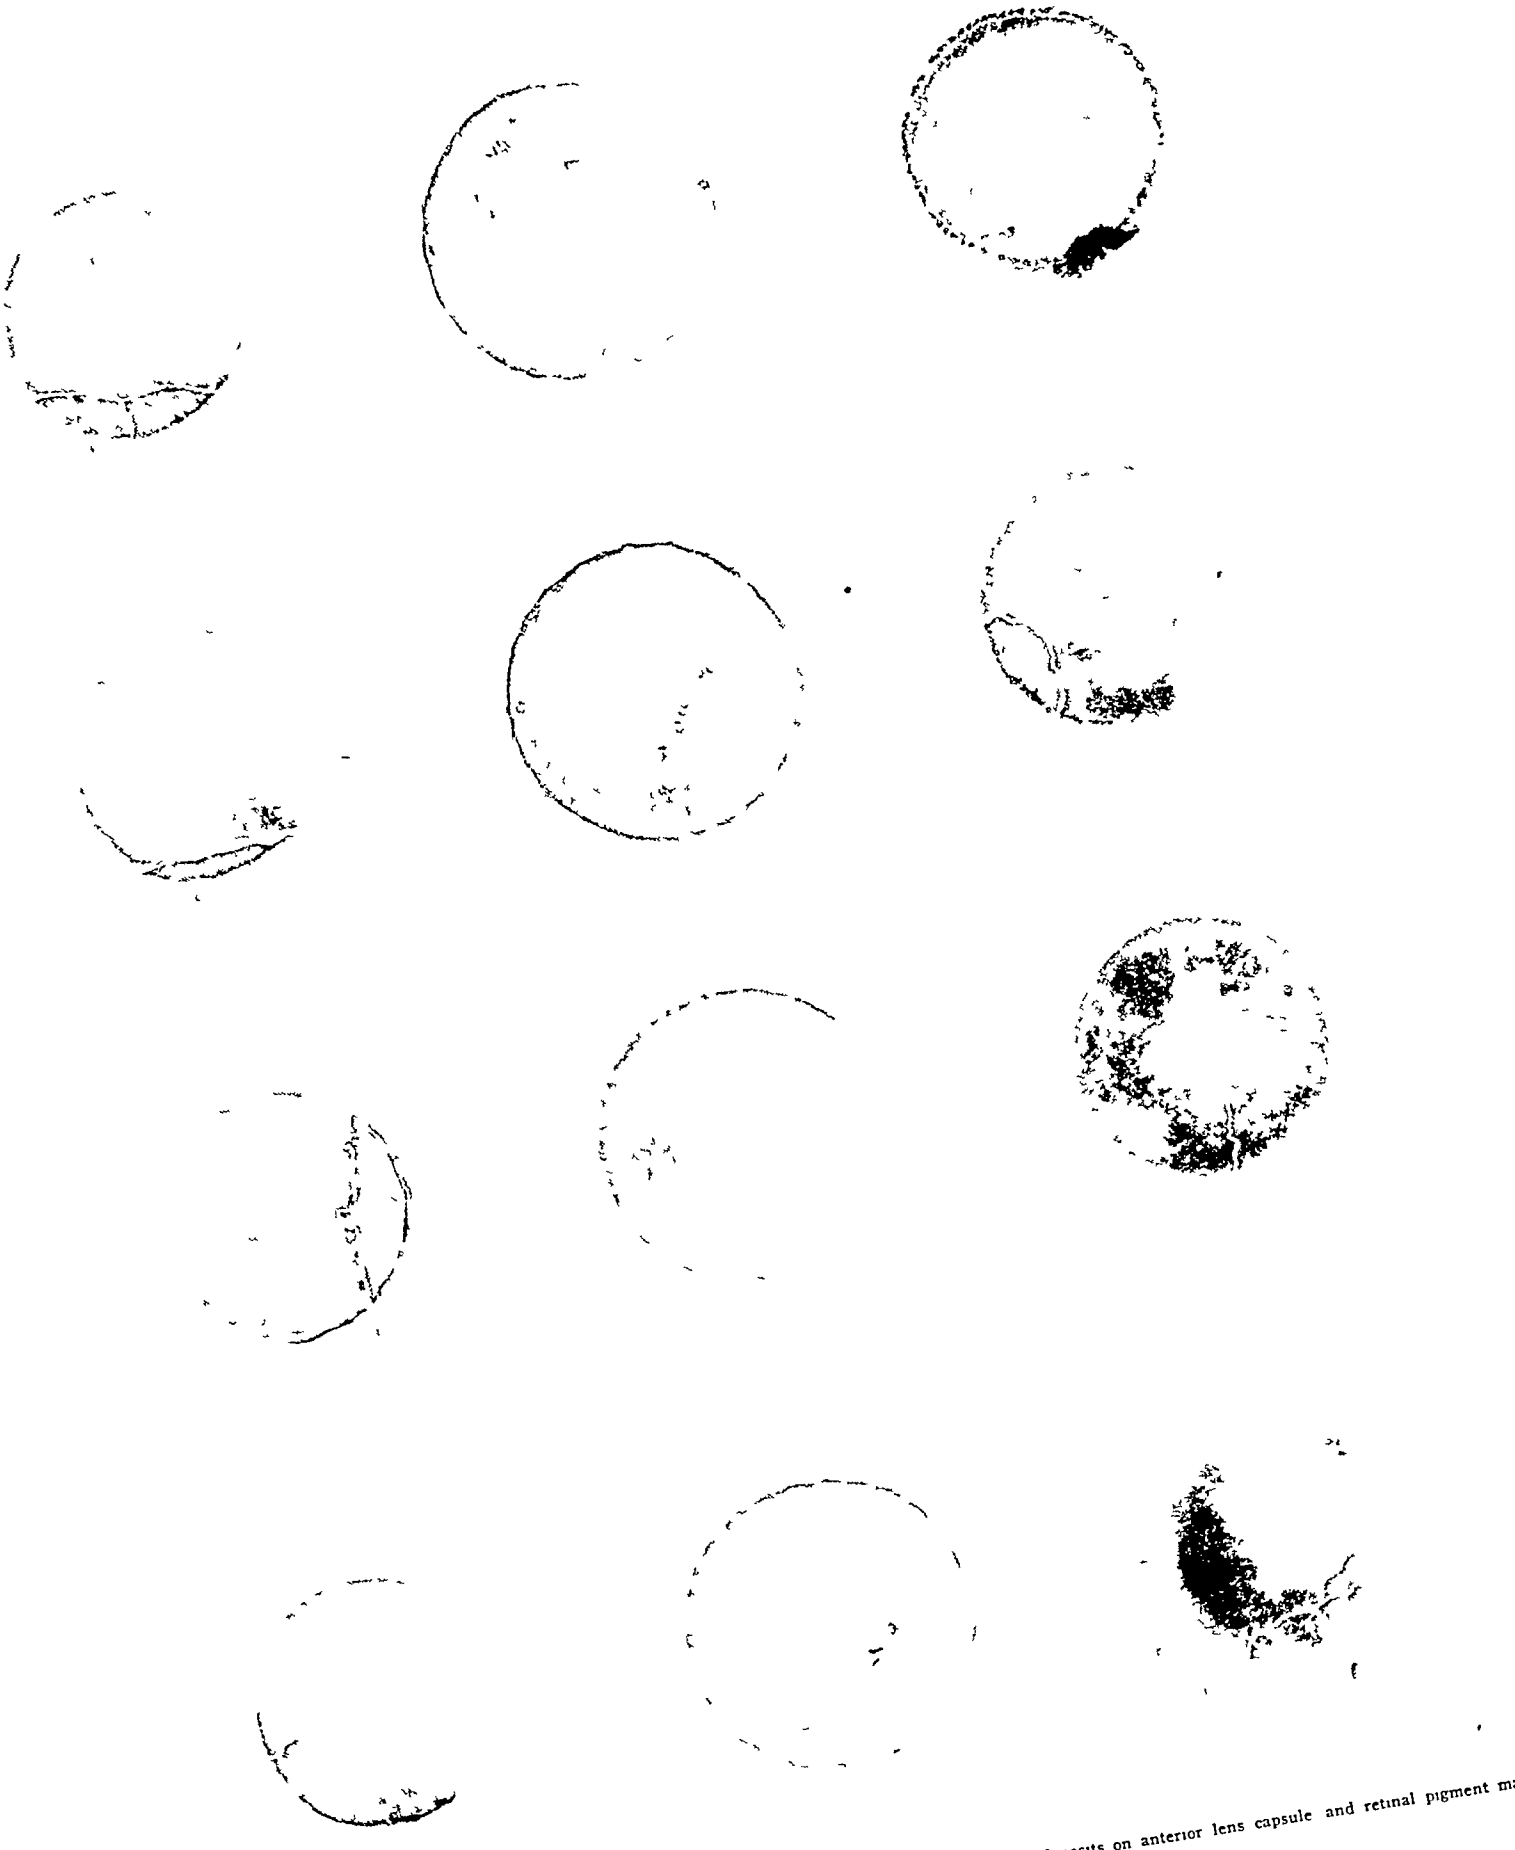

Fig. 4—A few of the many embryologic changes: filaments from shelf of iris; pigment deposits on anterior lens capsule and retinal pigment mass adherent to iriss troma

is probably never present except in disease Balls, small definite, round, projecting masses which may cover the entire surface of the iris or even lie on the anterior lens capsule, have been seen in the dark brown iris only when the patient had glaucoma The interpretation of pigment dots, particularly those near the pupillary margin, is open to discussion They have been seen in seemingly normal eyes, in those with atrophic iris, and in some with cortical cataracts They are usually superficial, tend to round shape, and most often are of the retinal pigment type Dense granules, sometimes in the form of a thick veil, have with one exception never been seen except in glaucoma

EMBRYOLOGIC REMNANTS

The origin of tissue must be considered, if anomalies are to be properly recognized As the eye develops, the uveal tract forms a mass which becomes the posterior lens capsule This projects forward and makes a sheath or a layer of vascular tissue Ordinarily, this layer is absorbed, but at times it persists as a macroscopic body in the pupillary area At other times, the

Fig 5 —Sympathetic ophthalmia Above Descemet s deposits Below one of many new blood vessels in iris and on capsule The iris shelf is adherent to the capsule not the pupillary margin This is seen only in chronic uveitis

remnant is so small that only careful study by focal illumination and the ophthalmoscope discloses it There are, however, many other changes which have escaped clinical detection In my first 250 examinations there were forty-three anomalies, a few of which may be studied by examination of the chart

Fig 6 —Congenital coloboma with pupillary margin tags The retinal pigment is almost complete only the most inferior margin being without it. Congenital cataract

EMBRYOLOGIC CHANGES

There are two great classes of embryologic changes, those of iris structure and those of pigment on the anterior capsule of the lens

Iris Structure—First, folds that spring from the iris shelf and have the character of the definite iris stroma These bands may be single, they may project into the pupillary area, or, as we have seen in two cases, extend to the capsule of the lens and remain adherent to it or the fiber may simply extend forward and almost touch the cornea Second, fine translucent gray filaments which may remain attached to the iris at one end and lie free in the aqueous at the other or extend from the iris to the anterior capsule of the lens or from iris to iris or go across the pupil from iris to iris By examination, preferably dark field, many of these forms are easily seen, and it will be found that they all come from the iris shelf A part of the iris may be absent, as in coloboma, or all of it, as in aniridia

Pigment—Congenital deposits of pigment are of three types stars, masses and fine lines The stars may be single or in groups The indefinite dense brown pigment may be in rounded, elevated areas single or multiple Fine lines may lie on the capsule and extend beneath the iris In this study stars and lines have been

seen only in otherwise normal eyes On the other hand, splotches of pigment similar to these congenital ones have been seen in iritis and glaucoma

PATHOLOGIC CHANGES

Iritis—Acute In acute iritis, the first clinical change is contraction of the pupil or sluggish light reaction, which is followed by injection and then exudation Most of the synechiae are the result of exudate causing the adhesion of the retinal pigment layer to the anterior lens capsule At first there are minute aggregations of cells which, if seen early, can be drawn apart under atropin and may leave no trace of the disease More often, however, the adhesions are well formed, showing as a gray exudate surrounded by brown pigment Atropin may succeed in stretching these, but there always remains some retinal pigment on the capsule, and not infrequently the iris is firmly bound down Such posterior synechiae vary in size, number and shape The gray exudate that partially or completely fills the pupillary area is well studied, and conclusions may easily be drawn When a ring of the exudate completely closes the anterior chamber, the iris bulges forward, often causing glaucoma Not infrequently the iris seems bound down throughout its entire margin, and yet glaucoma does not supervene Examination in the latter case will show that there is at least one area in which the iris is free from the capsule

Chronic In chronic iritis there are two noteworthy observations (1) the adhesions of which I have just spoken, and (2) the proliferation of the retinal pigment This pigment may cover the entire anterior capsule, it may be present as a single small mass, or there may be any degree of pigmentation between these two

Quiet The type that escapes diagnosis and is, therefore, called "quiet iritis" is easily diagnosed with the lamp The pigment proliferation and gray capsular exudate in an eye without pain and only slight redness make the diagnosis easy In syphilitic iritis we may have the so-called gumma, which appears as an elevated

Fig 7—Chocolate colored deposits in and on the iris with a capsular exudate and pigment proliferation Chronic glaucoma

brownish area with definite blood vessels running in and through it Tuberculous iritis offers a field for interesting study and exact deductions

Recurring Recurring iritis has caused endless annoyance to patient and physician A thorough study will show that in many of these cases there is complete occlusion, and that the flushing of the eye is often indicative of a glaucomatous change This explains why an iridectomy has often cured an iritis of years' standing

INTERSTITIAL KERATITIS

In interstitial keratitis, the iris usually presents the inflammatory picture with opacity and vascularization of all layers of the cornea, and areas of deposit on Descemet's membrane As there has been some doubt as to the circulation of blood in interstitial keratitis,

Fig 8—Penetrating iris injury caused by a flying piece of steel Retinal pigment layer in the wound no pupillary marginal pigment change

that doubt is permanently removed after examination with the slit lamp, for, in all fresh cases, the definite blood stream is demonstrable, and only in permanent, small, central opacities is blood absent Descemet's deposits vary much in size and number, frequently covering almost the entire membrane Often grouped to one side of a deposit are rounded dots suggesting a granular nucleus in appearance So far, I have not been able to make a definite diagnostic deduction regarding these deposits

A case of proved tuberculous keratitis with temporal limbus infiltration of many months' duration showed a clear iris, with no evidence of infiltration or increased iris vascularization

UVEITIS

A patient with secondary uveitis, of unproved syphilitic origin, of years' duration, presenting many vascular corneal opacities, had a mature cortical cataract three years ago The lens was removed, pupillary occlusion became marked and the patient came to me for a second operation The slit lamp proved that she had innumerable gray patches of deposit on Descemet's membrane, and that many new blood vessels were present in the iris The other eye showed the same deposits and corneal vessels These Descemet's deposits were so minute that, unless a most exhausting loupe examination had been made, they surely would have escaped notice It is hardly necessary to say that I refused to operate

SYMPATHETIC OPHTHALMIA

The appearance of the iris in sympathetic ophthalmia is suggestive In one case, Descemet's membrane was studded with deposits, the iris was thickened and lost its markings, and there was adhesion between the shelf and capsule, with a frayed margin and many large blood vessels This iris picture was almost the same

in an eye that had been severely injured by being struck with a large foreign body, producing dislocation of the lens up and out with iris inversion The iris was brownish, showing fine and large blood vessels with triangular attachments of the iris shelf to the capsule

Fig 9 —Traumatic iridodialysis intact pupil margin, no pigmentation, zonule and lens

INJURY

Figure 9 shows the separation of iris, the result of a blow It will be noted that the peripheral margin of iris is smooth, and that there has been no increased pigmentation

In a clean-cut perforating wound there was a distinct layer of retinal pigment where the overlying iris had been destroyed with no other evidence of iris involvement A clean prolapse of iris which became incarcerated in the cornea showed a stretching and thinning of all iris structure without pigment massing

GLAUCOMA

The observations made on glaucoma are classified as acute, chronic and simple

Acute —The opportunity of studying the acute cases with the slit lamp has not been often As may be readily understood, the excited patient stands such an examination poorly, the eye being so sensitive to light

In a recent case the cornea was steamy, showing innumerable superficial epithelial elevations and true edema, the pupil was widely dilated with injection of the iris but no change in the pigmentation

Chronic —The chronic inflammatory glaucomas are more often examined, and usually show migration of pigment Some, however, do not, so that it does not seem that pigment migration is either a symptom of the disease or of prognostic import, although it may prove to be of the greatest diagnostic value

Simple —Simple glaucoma has been observed many times, some showing absorption of almost all of the iris pigment, the iris giving the appearance of being moth-eaten because of its uneven margin and transmitting the light through the atrophic tissue to the retinal layer

On careful focusing it can be found that a blue iris is made up of a very few strands near the pupillary margin, and the tissue making up the shelf is so thin that the pigment layer is detailed In other simple glaucomas, the iris margin has remained unchanged, and in still others the pupillary pigment layer seems to project over the iris, giving an appearance of prolapse Not infrequently the iris blood vessels are very numerous, although gross examination may not demonstrate it This is one reason why expulsive hemorrhage follows operation, such as an iridectomy

Another reason for failure to relieve tension is the immediate adhesion of the iris to the lens capsule I strongly urge the use of atropin at and following operation

CATARACT

Following cataract extraction, not uncommonly the whole surface of the iris seems obscured in a thin veil in which there are innumerable pigment spots not only about the pupillary margin but as far back as examination can be made In some other cases the iris about the coloboma is atrophic, showing as a gray line with irregular margin and, by dark illumination, loss of iris

Fig 10 —An adherent leukoma secondary glaucoma a broad iridectomy vision 20/30 Type 1 The iris incarcerated in the ulcer is evident as a thin atrophic layer The margins about the iridectomy and pupil show a few narrow synechiae and the superior temporal side a large irregular triangle of unaltered retinal pigment Fine pigment over and in stroma

fiber detail In other cases, particularly in brown iris, the margin seems thickened and rounded, and gives the effect of considerable pigment proliferation

SUMMARY

Anatomic and embryologic changes heretofore only partly studied and very infrequently seen clinically are now a matter of daily observation

Iritis can be diagnosed earlier, and prompt, efficient treatment materially lessens the severity of the attack

After the attack, correct measures may be instituted for the prevention of recurrence, such as iridectomy in occlusion

Although the iris, retina and choroid are directly continuous, the surprise has been the absence of any iris change in retinochoroiditis, neuroretinitis, simple detachment of the retina, choked disk or retinitis proliferans

Glaucoma may be diagnosed earlier by the slit lamp, but it seems to me that if the methods we now have of careful tonometry and field observation have not helped an individual observer, then the more difficult of interpretation pigment migration is not likely to clear the diagnosis, for such migration has been seen in high myopias, compound hypermetropic astigmatism, hyperopia, primary optic atrophy with arteriosclerosis, and in cataracts of the cortical, capsular, lamellar, traumatic and secondary types

In some penetrating wounds of the iris there is no change except at the direct site of injury, in contrast to the retinal pigment massing in any iris inflammation

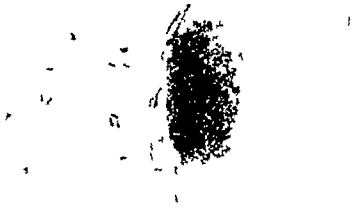

Fig 11.—Chocolate colored deposits in and on the fibers of the iris in a boy aged 11 years whose only lesion was a low degree of hyperopic astigmatism

CONCLUSIONS

Variations from our previously considered normal are many Marked gross iris changes are better understood after study with the lamp

The inflammations of the iris may be promptly recognized

Glaucoma can sometimes be confirmed by examination with this instrument

The pigmentation of the iris demands the most painstaking study by many competent observers for some time

Favorable and unfavorable cases for operation may be selected by its use

Finally, the slit lamp is an addition to our diagnostic armamentarium only second to the ophthalmoscope, and, just as the older instrument yields results only after training, so the newer can be of its greatest service only after long study

344 State Street

ABSTRACT OF DISCUSSION

DR HARRY S GRADLE, Chicago A question that is essentially of physiologic but eventually of pathologic interest is that of the approximation of the sphincter margin of the iris to the anterior capsule of the lens Many authors led by Hamburger, believe that this approximation results in a water-tight closure between the anterior and the posterior chambers while those of the Leber school are convinced of the free communication between the chambers A conclusive decision on this point would be of vast importance, with especial reference to the mechanical features of glaucoma In a case with a localized, sharply defined area of atrophy in the iris stroma, the entire iris tissue of the area was replaced by a thin, flexible membrane, essentially a tambour of the iris The membrane bulged forward until it protruded markedly before the anterior plane of the iris Then suddenly it collapsed and resumed the former position in the plane of the retinal pigment epithelium of the iris This phenomenon was interpreted as the result of a water-tight closure between the anterior and posterior chamber until the pressure of the aqueous in the posterior chamber was sufficient to overcome the approximation of the iris to the lens capsule, when the fluid spurted through the pupil, relieving the pressure on the posterior surface of the flexible membrane in the iris I have observed a somewhat similar phenomenon in a young girl with congenital cataract One lens had been needled twice, with the result that the anterior capsule was wide open and well retracted behind the iris There were still a few floccules of cortex in the bed of the

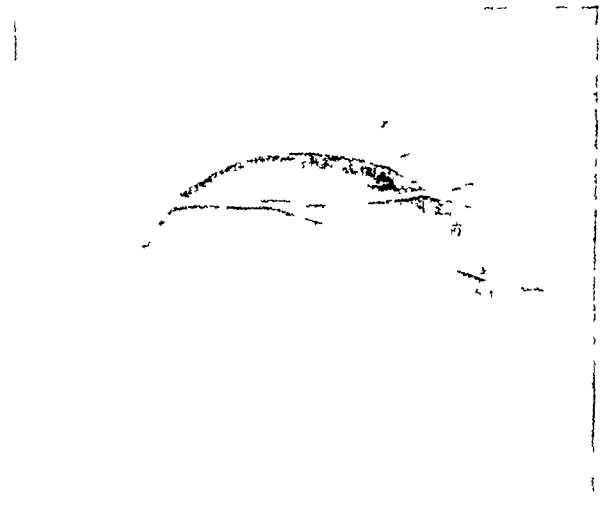

Fig 12.—Retained pupillary membrane showing many fibrous attachments to the iris shelf

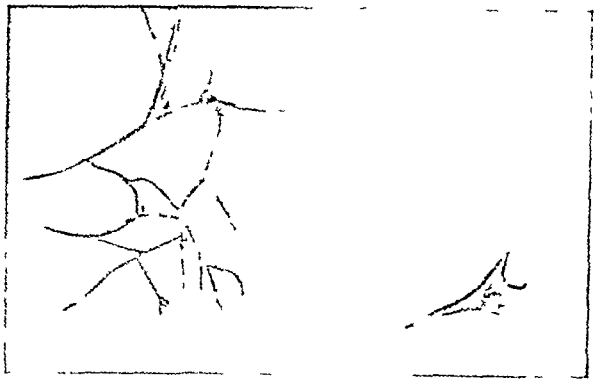

Fig 13.—A group of congenital pigment cells on the anterior capsule Patient had retinal blood vessel tuberculosis

lens, and the posterior capsule was fairly opaque In the exact center of the posterior capsule was a round aperture, approximately 2 mm in diameter, through which she obtained normal vision with the proper correction With the slit lamp this aperture was found to be covered with a membrane so delicate that it could not be seen with the usual Coddington loupe The membrane resembled a spiderweb in formation, minus the geometric regularity, and it could not be determined whether it was new formed tissue, hyaloid membrane, or thickened anterior vitreous Irrespective of the source, it was extremely delicate and flexible The membrane bulged forward fully 0 5 mm and then receded to the primary position in the plane of the posterior capsule The bulging occurred in the form of a tidal motion synchonous with the respiration and continued throughout the period of observation In all probability the pressure of the blood in the retina and choriocapillaries is increased during some phase of respiration, as is the pressure of the blood in the anterior portion of the eyeball But the volume of blood behind the posterior capsule is much greater than that of the anterior portion and consequently an equal increase in blood pressure throughout would result in slightly greater pressure in the vitreous chamber than in the aqueous chambers Such a slight change in pressure is insufficient to cause a manifest difference in an eyeball with normal relations, but the delicate membrane in the posterior cupsule, acting as a tambour head, allowed the observation of slight pressure variation between the vitreous and aqueous chambers

DR MARCUS FEINGOLD, New Orleans I would like to relate the purpose for which I use the slit lamp and corneal microscope on the iris in certain instances A young man complained of a dilated pupil in his left eye He had had no discomfort He had been strong and well and was not aware of any disease I found an extremely dilated pupil, weakened accommodation, and a pupil which did not react at all to light The physical examination was entirely negative the Wassermann was negative There was weakness of the extrinsic muscle in the other eye My suspicion was that we were dealing with a case of lethargic encephalitis, one of those cryptic cases in which there had been no other manifestations of disease Nothing was found by his family

FIG 14.—Acute iritis masses of retinal pigment layer on capsule iris stroma freed

physician Less than a year later, he appeared again, with the same condition I examined him with the corneal microscope and slit lamp, for the purpose of establishing whether any pupillary reaction existed With a binocular loupe and focal illumination and an electric ophthalmoscope I could detect no movement whatever of the sphincter With the corneal microscope and slit lamp I found that on the temporal side the sphincter reacted, on the nasal side it did not react Of course, this did not lead me any farther in diagnosis, but it is an interesting observation, and the future will tell what the case is

DR MARTIN COHEN, New York Might it be wise to examine the iris tissue in regard to pigmentary changes in cases of suspected systemic disease, for instance, diabetes? Would we be able by the slit lamp and corneal microscope to recognize incipient pigmentary changes in the iris stroma?

DR. ARTHUR J BEDELL, Albany, N Y I have not seen any marked pigmentary changes in the conditions of which Dr Cohen speaks I particularly mentioned in the paper that in diseases in which we would expect to find some pigmentary changes, we have been surprised to find they were

FIG 15.—A congenital film veil coming from the iris shelf with a frayed end projecting forward Three pigment masses round smooth and without demonstrable structure The inferior end lies behind the iris

not present Dr Feingold spoke about pupillary reaction You all know how difficult it is at times to decide whether or not a pupil reacts I think the most accurate method is to have the patient before the slit lamp with the iris well focused and then turn the light on and off In this way, even the slightest reaction is easily determined

SOME COMPARATIVE RESULTS IN CITIES AND IN COUNTIES AS HEALTH UNITS*

A J WARREN, M D
Director of County Health Work Kan as State Board of Health
TOPEKA, KAN

The incorporated city is a unit of civil organization for the protection of the public health has so thoroughly justified its existence, efforts and expenditures that the question of the propriety of such an organization is no longer debatable The evidence is all on the affir native side

Unfortunately, the county as a unit of organized civil efforts for the protection of the health of the people living in the rural communities and small towns is not so universally accepted That the county as a unit has been neglected in the past is illustrated by the fact that the first position of full-time county health officer in this country was not established until 1911 [1] That the problem is still being treated with indifference is evidenced by the fact that of the 3,065 counties or equivalent divisions of the continental United States, only 161, or 5 2 per cent, were on Jan 1, 1921, provided with a whole-time local health service In other

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Pub Health Rep Nov 18 1921 p 2832 2836

words, only 8 21 per cent of the rural population of this country was on Jan 1, 1921, provided with local health protection [1]

"The country is the weakest link in the sanitary chain" [2] because the country has been neglected on account of the prevailing opinions that "rural health work, on account of distance to be covered and other obvious factors, is relatively more expensive" [3] and difficult than urban health work Such opinions have apparently been accepted as sufficient justification for indifference in applying the remedy, without the necessary evidence to demonstrate either the truth or the fallacy of the accepted hypothesis The result of this accepted situation regarding cities and counties as health units has been a severe distortion of the once established facts The urban death rates have declined as the result of the application by well organized municipal health departments of known sanitary and hygienic principles The rural death rates have remained undisturbed as a result of the lack of application of the same principles, until controversy is rife in regard to whether the city or the county has the highest death rate

The fundamental principles involved in the prevention of typhoid fever are the same for the country as for the city, and they are the same the country over The same is true of smallpox, diphtheria, infant mortality and other diseases concerning which we have

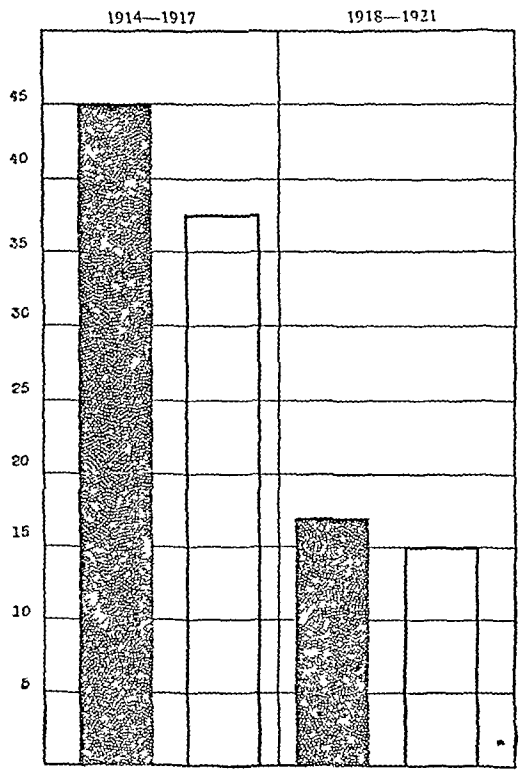

Chart 1 —Comparative typhoid death rates before and after the establishment of health departments shaded area cities white area counties

fairly accurate knowledge The only difference is in the practical application of the fundamentals involved to the given area And even here differences are apparent only in the execution of the details, and are not general Natural factors also favor the country dweller,

2 Rosenau Preventive Medicine and Hygiene p 475
3 Lumsden L L Pub Health Rep 36 2472 (Oct 7) 1921

and the present conditions are a reproach to our lack of efforts and intelligence

In order that some evidence might be made available to disturb the present equilibrium toward which we are approaching, an effort was made to determine the relative cost of, and effectiveness of, public health work in

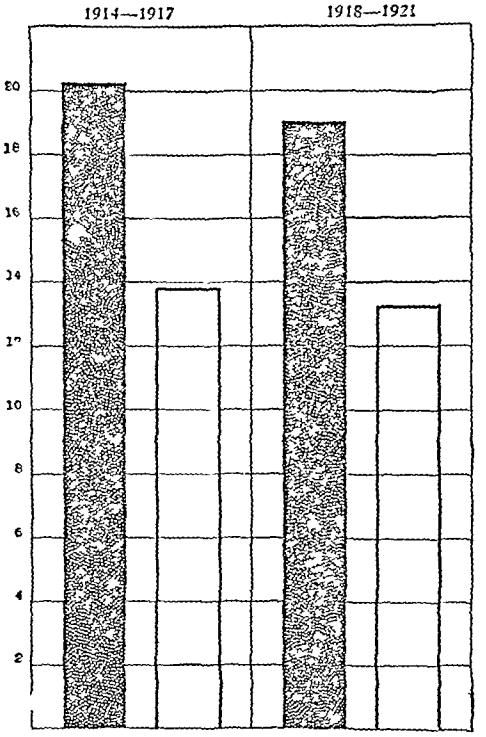

Chart 2 —Comparative gross death rates before and after establishment of health departments shaded area cities white area counties

urban and in rural communities A survey covering three cities and nine counties, all having well organized health departments, was undertaken [4] The survey covered a period of eight years and involved a total average annual population of 461,244 Of this number, 108,534 lived in the three cities, and the remaining 352,710 lived in the nine counties The cities ranged in population from 27,076 to 50,992 in 1921, with an average annual population for the four year period 1918 to 1921, inclusive, of 36 178 The counties ranged in population from 23,141 to 54 954, with an average annual population of 39,190 each for the four year period 1918 to 1921, inclusive The cities and counties surveyed were all located in the central two thirds of the state of North Carolina, for the reason that in no other locality were the imperative factors of age of units and extensiveness of activities so favorable, and because of the fact that it was essential that the counties and cities involved should have some definite relations to one another The counties and cities surveyed were all organized on a full-time basis on dates that were separated only by a few months This wholesale organization took place between Jan 1, 1917, and Jan 1 1918

The relative nearness of the dates of organization makes possible a division of the eight year period into two halves one from Jan 1, 1914, to Dec 31, 1917, a four year period prior to the influences of organized health protection the other from Jan 1, 1918, to

4 Cities of Charlotte Raleigh and Winston Salem Davidson Edgecomb Forsyth Lenoir Northampton Pitt Robeson Rowan and Wilson counties (North Carolina)
5 Wilson County Sept 1 1916 city of Raleigh Oct 10 1916

Dec. 31, 1921, a four year period during which the effects of organized public health efforts exert a positive influence on the respective communities. The nine county organizations were identical in personnel, plan of work and budget. The cities, while not so nearly identical as the counties, were similar in personnel, activities and budgets. In two instances the city health departments were organized and conducted for a short period by a personnel representing the United States Public Health Service. The three major problems of public health work—(1) the reduction of the filth-borne diseases of which typhoid fever may be regarded as the criterion, by means of sanitation, education and immunization, (2) the control of contagious and communicable diseases by quarantine, education and immunization, and (3) the reduction of infant mortality—were the activities that were first undertaken by the city and county health departments. It is possible, therefore, to compare with some degree of satisfaction the results after four years of organized effort, as expressed in the specific mortality rates, the gross death rates and the per capita expenditures.

TYPHOID FEVER

While there is no one perfect index by which to gage the results of the effectiveness of public health work, the one specific disease that approximates most closely this condition is typhoid fever. "The cause, mode of transmission, and prevention are well understood in theory and readily attainable in practice. Sanitation here finds its first fruitful field, hygiene, its useful lessons, and immunology its special application."[6] The degree of the effectiveness of the application of these principles will be very definitely expressed in the reduction of the specific mortality rate to a greater or lesser degree. And the application of these principles is the only known process that will abruptly alter the specific mortality rate in a community in which typhoid has been consistently prevalent over a period of years.

For the three cities, the typhoid death rate for the period 1918 to 1921, inclusive, shows a reduction of 62.13 per cent., as compared with the four year period 1914 to 1917, inclusive. For the same period of time the nine counties showed a reduction of 60 per cent. in the typhoid death rate.

The state as a whole (exclusive of the three cities and nine counties) for the same period of time showed a reduction of 49.55 per cent., which gives the cities a reduction in excess of the whole state of 20.24 per cent., and the counties a similar reduction of 17.41 per cent.

It is to be noted that while the cities show a slightly greater reduction in the typhoid death rate, the county rate is 11.7 per cent. lower than the city rate, and 3.8 per cent. lower than the rate for the state as a whole.

TABLE 1.—TYPHOID DEATH RATES*

	Cities	Counties	State
1914-1917	44.9	37.3	31.38
1918-1921	17.0	14.9	15.83
Percentage of reduction	62.13	60.0	49.55

* The statistics were supplied by the Bureau of Vital Statistics, North Carolina State Board of Health.

6. Rosenau, Preventive Medicine and Hygiene, p. 105.

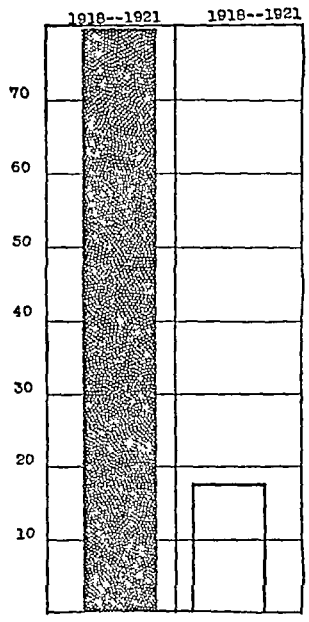

Chart 3.—Per capita expenditures in three cities and nine counties for health departments; shaded area, cities, white area, counties.

GROSS DEATH RATES

The composition of the population living in the rural area and the small towns, and in the cities as regards age, sex and nationality are of sufficient similarity to make a comparison of the gross death rates between the urban and country areas of considerable value.

TABLE 2.—GROSS DEATH RATES*

	Cities	Counties	State
1914-1917	20.3	13.8	13.10
1918-1921	19.0	13.3	13.33
Percentage of reduction or increase	—6.4	—3.6	+1.7

* The statistics were supplied by the Bureau of Vital Statistics, North Carolina State Board of Health.

For the three cities, the gross death rate for the four year period from 1918 to 1921, inclusive, decreased 6.4 per cent., as compared with the four year period 1914-1917, inclusive. For the same period the nine counties showed a reduction of 3.6 per cent. A very significant factor to be noted here is that while the cities show a much greater reduction in the gross death rates, the excessive gross death rates of the cities make the reduction relatively easier, and make a greater reduction possible in the cities. While the cities have shown a greater percentage of reduction of the gross death rates, the city death rates are still 30 per cent. in excess of the county death rates.

For the same period of time the gross death rate for the state as a whole (exclusive of nine counties and three cities) showed an increase of 1.7 per cent. All of this increase was for the year 1918, when the mortality from influenza reached its crest in the state. This fact makes the reduction in the three cities and nine counties the more significant.

PER CAPITA COST

All money expended for public health purposes should have a twofold objective (1) the reduction of morbidity and (2) the reduction of mortality. As yet we have no universally accepted standard for determining the reduction of the morbidity. Probably the mortality rate is as accurate an index of morbidity as any of the methods that have been advocated. At the present time the mortality rates must serve as the twofold index for estimating the degree to which the money that is expended has accomplished its original objectives.

In reducing the mortality rates 6.4 per cent., the three cities expended the sum of 79.9 cents per capita. The

TABLE 3.—POPULATION AND EXPENDITURES

	Annual Population	Annual Expenditures	Annual Per Capita Cost
Counties*	39,190	$ 6,835.60	$0.174
Cities†	36,178	28,911.92	0.799

* Data furnished by Bureau County Health Work, North Carolina State Board of Health.
† Data furnished by city health officers of Charlotte, Raleigh and Winston-Salem.

nine counties spent 17 4 cents per capita in effecting a reduction of 3 6 per cent in the gross death rates

CONCLUSIONS

The conditions in North Carolina are not representative of the conditions in Kansas or in Maine The cities and counties of North Carolina do, however, have a definite relation to one another The cities and counties of any other state have a similar relation

The parallel that has been drawn is not exact No similar comparison can be exact

The evidence submitted proves, conclusively, nothing It does, however, suggest that the charge that rural health work is more expensive and difficult than urban health work needs modification, if not a complete withdrawal

---

ABSTRACT OF DISCUSSION

DR W S RANKIN, Raleigh, N C As to the importance of developing full-time county health departments, and the comparative ease with which such work is done, I think that all state health officers who have concerned themselves with this problem have been encouraged with their success in inducing the counties to see the importance of making arrangements for taking care of the health and lives of their people The full-time county health officer problem is, in a sense a psycho epidemic affair Get a few counties started and produce results Establish a fairly practical satisfactory plan to work and it is easy to carry the idea into the adjoining counties When one considers the opportunity in this particular field as compared to the opportunity of developing urban health work, and when one thinks of the 3,065 counties in the United States with only 6 5 per cent having full-time health departments, one can see what a vast field of opportunity exists In the South it has been much easier in recent years to develop rural than urban health work. The main restriction in rural health work is not the willingness of the people to put in a health department but the difficulty of obtaining health officers who can put through the idea that the people have endorsed In going into a county, the usual procedure is to see first an influential group of men In my opinion the influential group which should be consulted first is the professional group We have neglected too much the matter of conferring with the local profession It does not make any difference what we are going to have done in that county, it has to be done through the local profession The recognition and prevention of disease and clinical diagnosis are things for which one has to depend on the local profession The doctors ought to be seen first if for no other reason than as a matter of proper respect The profession, because it has not been consulted as it should have been, has not understood what was going on, and the lack of cordial relations has resulted in a certain indifference Ordinarily it is easy to get the approval of the county medical society to put in a county health department if one presents a reasonable proposition When health officers fail to get the approval of the county medical society for a full-time health department, it means that either the profession of that county is unreasonable or that the man who is selling the proposition is not a good salesman I want to add my full endorsement to the conclusions drawn by Dr Warren

DR J A HAYNE, Columbia, S C I have neither respect for nor confidence in any statistics but Dr Warren s statistics are extremely interesting He showed that with a per capita tax of 15 cents a considerable reduction could be made in the death rate of the rural population Coming from a state that has 85 per cent rural population, this is a matter of some interest The full-time health officer was stressed for a long time I never believed much in whole-time county health officers I do believe in whole-time county health departments County health officers cannot do well without sufficient support They must have the same support as a city department of health Some years ago we had the idea that in a county thirty miles long and twenty miles wide one county health officer could accomplish results by simply being there We found that this did not do any good except to provide a rather comfortable place for the man who had the position At present we believe in having county health departments with trained county health officers at the head, a nurse or two, sanitary inspectors and a clerk-stenographer, and if necessary a sanitary engineer and all the necessary equipment for doing proper health work Most counties have more than 30 000 population Would a city of 30,000 population think it was doing justice to the people if it did not have a health officer? Why does a county of 30 000 population think it is doing its duty to the citizens by having health officers who occasionally appear during epidemics and usually make themselves very disagreeable to the physicians? In South Carolina the medical profession of the state is the department of health of the state That is the proper way That is the board of health that is going to succeed When you leave out the physicians and try to put in health officers you are going to fail

DR W L HOLT Knoxville Tenn I had some experience in county health work in Los Angeles County, California All the rural health work in the county of 4 000 square miles was managed from the central office in Los Angeles We had two or three deputy health officers and about six nurses and two inspectors and did a great deal of work The splendid roads everywhere enabled us to travel fast by automobile, and I often traveled a hundred miles a day in visiting only a half dozen cases The cost of administration for each case is much greater than it would be with about six cooperative health departments, each covering both the urban and rural territory in its district Of the total population of about a million in the county about 800 000 were inside the thirty three cities and towns in the area and cared for by municipal health departments The remaining 150,000 were scattered all over the great county and were cared for by the county health department in an efficient but uneconomical way

---

AN EXPERIMENT IN GRADUATE TRAINING IN OTOLARYNGOLOGY*

GEORGE E SHAMBAUGH, M D
CHICAGO

Facilities for providing training in otolaryngology have not kept pace with the public need for specialists or with the demands of those desiring to take up this work

A survey of the situation reveals the fact that substantial training in otolaryngology is being provided in a few special hospitals, but, of course, only for the limited number of men which the needs of these hospitals require as interns For most of those who attempt to get special training, there remains only the opportunity of taking such work as is provided in postgraduate schools Before the war, there had developed an increasing tendency for men to seek training by going abroad This work, like that of postgraduate schools, was restricted largely to attendance at clinics and to the taking of short intensive courses, suited especially, as review work, for those already established in special practice, but not for providing the proper fundamental training necessary for preparing men to be specialists in any field Even the training acquired by serving as intern in special hospitals has been more or less one-sided, for these men necessarily see an overemphasis on operative work, and have relatively little opportunity for the more difficult and much more important training in

* Read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

making careful examinations of patients and in diagnosis. The lack of facilities for acquiring a proper preparation for special practice, the faulty training acquired in our existing institutions, where operative technic is chiefly emphasized, with a neglect of proper attention to the more important and more difficult problem of acquiring training in making examinations and in diagnosing conditions, has resulted in the tendency for indiscriminate, unnecessary operating, which has, in recent years, brought a distinct opprobrium on the specialty of otolaryngology. In recent years, I have seen many more patients in whom there had been uncalled for operation on the nose and throat than patients in whom operative treatment seemed indicated.

The question of what constitutes the proper minimum standard of preparation for the practice of otolaryngology was discussed by the Council on Medical Education of the American Medical Association at its meeting a year ago.[1] The committee on otolaryngology, in its report, insisted that the work should be as much in the fundamental sciences as in the clinical study of cases, and that the work must be on the basis of genuine graduate instruction, in which the student is led to do his work independently under proper supervision, but not by the method of forced training, that is, by taking didactic courses and clinics. This committee further recommended that a proper minimum training for special practice should consist of one year's full-time work, one half of each day being spent in the laboratories of a university studying the fundamental sciences, the other half day in a properly equipped and properly organized outpatient department of a Class A medical school, where the student occupies the position of clinical assistant. On the completion of this first year's fundamental training, the committee recommended that a second year be spent in serving as intern in a special hospital, or as resident in otolaryngology in a general hospital. When such positions are not available, it was recommended that an additional six months be spent pursuing special work in other centers, such as selected courses in postgraduate schools, or by serving as assistant in the office of a specialist.

I desire at this time to point out some conclusions regarding graduate training in otolargyngology which we have reached, after more than two years' experience, in an effort to carry out the principles laid down in the report mentioned above.

The first conclusion of primary importance is that facilities for providing the proper sort of graduate training in our specialty in any institution exist only for a limited number of students. This is a fact which every institution must learn before it can hope to carry out successfully the proper sort of graduate training, as outlined above. The number of graduate students in any school is determined by the number of clinical assistants required to care properly for the work in the outpatient department. The principle is exactly the same as that which applies to the work of interns serving their fifth or hospital year, now required before receiving the degree of doctor of medicine. The number of interns in a hospital is determined by the number of men required to take proper care of the hospital work. It would be just as logical for a hospital to adopt the plan of taking on a superfluous number of interns and then attempting to substitute for actual intern work some sort of didactic instruction, attendance on clinics, etc., as it is to insist on these methods of instruction for large classes of graduate students in otolaryngology. The first principle in properly conducted graduate instruction is to lead the student to do his work independently, not by relying on methods of forced instruction, listening to didactic lectures or watching other men do their work.

In our outpatient department at Rush Medical College, we have, at present, facilities for only eight clinical assistants. Our class of graduate students in otolaryngology, therefore, is limited to eight men, who remain with us for one full year, working every afternoon in the outpatient department. This may seem a small number of graduate students for an institution with the clinical facilities of Rush Medical College. As a matter of fact, it is all that we are at present able to take care of properly, with our facilities. We feel satisfied that we are doing our full share by providing proper training for eight men each year. If only twelve of our best equipped Class A medical schools would arrange their work to provide proper clinical facilities for a similar number, the estimated needs in this country for specialists in otolaryngology would be amply provided for. The problem, therefore, of providing this first year of fundamental training is not a formidable one, but is easily attainable in our existing institutions.

I wish to outline briefly the way we have worked out the organization of the outpatient department, so that the work of these clinical assistants is properly supervised and directed, while they are, as far as possible, permitted to do the actual work of the clinic.

Two clinical assistants are taken on each quarter, January, April, July and October. During the first quarter, they are put to work examining the simpler types of nose and throat cases, learning how to make accurate records of their findings. For their direction in this work, we have provided an elaborate outline of the things to look for in making these examinations. The second quarter is spent in a similar manner in the ear room, learning how to make the various tests and the compilation of proper records. During the third quarter, they are at work again in the nose and throat room, where they are entrusted with the care of the more complicated cases and are permitted for the first time to carry out such treatments as require special technical skill, as, for example, the irrigation of sinuses. The fourth quarter is spent in the operating room, where they are taught the technic of operations and, eventually, are entrusted with most of the routine operating.

In this way, we are able to see to it that the student learns how to make examinations and to recognize the proper indications for surgical treatment before he is taught the technic of operating. A neglect of this fundamental principle has been responsible for the widespread ill-advised indiscriminate operating on the nose and throat with which this country has in recent years been flooded. The chief menace from this source has come from the practice introduced in many of our general hospitals of teaching interns in general medicine such operations as the enucleation of the tonsil, the removal of turbinated bodies and the resection of anatomic variations of the nasal septum. These men have had no opportunity to acquire an appreciation of the proper indications for these operations, and it becomes clear as day that men with such training cannot avoid the risk of doing unnecessary operations. It is a relatively simple matter to teach a student the tech-

1 Graduate Instruction in Oto-Laryngology. Report of Committee at Annual Congress on Medical Education and Licensure, A. M. A. Bull. 15: 40 (Jan. 15) 1921.

mic of operating, whereas, it requires many months of careful painstaking work to instil an adequate appreciation of the proper indications for these operations

The direction and supervision of the work of these graduate students serving as clinical assistants is entrusted to a staff of regular appointees in the department The staff is arranged in three groups, each group being in attendance but two afternoons of the week Our aim is to have three men in each group These men act as chiefs of clinic, directing and supervising the work of the clinical assistants, deciding questions of diagnosis, and what treatment is to be carried out The introduction of graduate students as clinical assistants has made the work of the regular staff more interesting and profitable, since they are relieved in a large measure of much of the routine work The patients are receiving better care than we were ever able to provide when we relied on physicians from the city to come out to help us with the work The graduate students are enthusiastic over their work, for they appreciate that they are getting a sort of training which no amount of didactic course-taking or attendance on clinic could give them

We find after a trail of more than two years, that our experiment is a complete success, and we believe that we have solved, for a small group of graduate students, the problem of acquiring proper training for undertaking special practice

I have discussed here only the half day devoted to the clinical study of cases Our plan contemplates spending the other half day doing the same sort of independent work in the laboratories at the University of Chicago, this time being largely spent in acquiring a first-hand knowledge of the complicated anatomy of the ear, nose and throat While pursuing this anatomic work independently, the students are encouraged to take advantage of lectures at the university covering such subjects as the physiology of the special senses, the anatomy of the central nervous system the anatomy of the special sense organs and the physics of sound Attendance on the lectures, two or three hours each week, of one of these courses each quarter does not interfere seriously with their major work in anatomy We believe that, by attending such lecture courses the students receive an introduction to those subjects which prepares the way for their pursuing such studies independently as facilities and inclination permit Those who desire may substitute, for part of their independent work in anatomy, similar work in the department of pathology

We aim to encourage these men, on the completion of the year's work with us, to secure, if possible, a place as intern in a special hospital, or as resident in otolaryngology in a general hospital, where they will have an opportunity of seeing more of the unusual surgical procedures We feel that eventually, when several of our Class A medical schools arrange their work to provide similar training each for a suitable group of clinical assistants, special hospitals throughout the country will choose to select their interns from men who have completed this first year's training We look forward also to the further development in various medical centers of short intensive courses covering the different phases of our special work, to which will be admitted these students who have completed the year's work as clinical assistants, as well as others who are already established in special practice We confidently hope that the time is not far off when such courses will not be offered as a substitute for the real graduate training as outlined for the Council on Medical Education in the report already cited

We wish to emphasize that the program here outlined as proper training for those preparing for special practice does not mean the giving up of instruction to large classes of graduate students, either in postgraduate schools or through similar courses undertaken by university medical schools But we do insist that this type of work can never form the basis of proper preparation for special practice, even when pursued over a period of months or years The foundation work of a proper preparation must consist in the student's receiving that training which can be obtained only by his serving an apprenticeship in actual work, such as the facilities of a properly conducted outpatient department can provide We repeat that special courses, clinics, etc, such as are provided in postgraduate schools and in some of our university medical schools, are suitable as advanced work for those who have had the first year of fundamental training, or as review courses for those already established in special practice They should not be offered as a substitute for the training we are advocating in this report Facilities for this kind of work exist in any institution only for the limited number of students necessary to aid in the proper care of patients in the outpatient department

The granting of a certificate suitable for display in the physician's office, setting forth that the holder has had adequate preparation for taking up special practice, would aid the public materially in distinguishing the bona fide specialist from the impostor, the pseudo-specialist recruited largely from the ranks of derelict general practitioners, whose sole preparation consists of a few weeks' or months' attendance on courses in postgraduate institutions, where they have acquired a smattering of knowledge relating chiefly to the technic of a few operations, but have acquired no proper appreciation of their indications, and who lack entirely the training necessary to prepare men for special practice Such certificates should properly be issued by the institution in which the first year's work has been taken, the certificate being granted only on the completion of such additional work as meets the approval of this institution

There has been much discussion of the question of requiring some sort of examination before granting a certificate setting forth that the holder has had the proper training preparatory for special practice The ophthalmologists have a special board for giving these examinations Our feeling is that an examination is not called for, and that a certificate stating that the student has completed certain work, including a year such as we have here outlined, is in itself a better assurance than any examination could possibly be that the holder has had proper training

As regards the granting of higher degrees, we can expect the universities to stand as ready to grant such degrees to students in otolaryngology as in any field, whenever the work pursued meets the established requirements for the granting of these degrees Those who are ambitious to hold important positions in the departments of otolaryngology in the university medical schools should be encouraged to pursue the studies leading to the degree of Ph D in otolaryngology, exactly as the men preparing for positions in the departments of anatomy and physiology intend to gain the degree of Ph D in anatomy or physiology before beginning their careers in these departments

CONCLUSIONS

1 The practice of otolaryngology has degenerated perhaps more than has the work in any other field of medicine This is the result of a widespread tendency for men to restrict their practice to this field with no preparation except a little training in the technic of a few operations The extent to which the work in this field has degenerated is indicated by the practice, common in some sections of our country, of visiting nurses selecting children for tonsil and adenoid operations, sending them to hospitals, where, often without examination, some so-called specialist proceeds to do the operation I should prefer to see the nurse trained to do the operation, provided a properly trained specialist made a discriminating examination and selected those cases in which surgical treatment was really indicated This indiscriminate operating on the tonsils and adenoids is a fair index of the general laxity regarding practice in our specialty

2 The bettering of existing conditions must be brought about largely by pressure from the rank and file of the general medical profession It should be our task to aid, by a propaganda of education, in crystallizing, in the minds of the general practitioner, ideas regarding the proper preparation for special practice Two popular fallacies must be dispelled the belief that limiting practice to a particular field makes of one a specialist in that field, and the idea that in taking up the practice of a specialty one is undertaking something easier than the practice of general medicine The medical curriculum aims to prepare its graduates for the practice of general medicine To be a specialist in any particular field should mean to make an exhaustive study of that field

122 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR JOSEPH C BECK Chicago I agree with everything Dr Shambaugh said We have, perhaps, enough places where men can get this training but they are not very well known So far as I know, Dr Shambaugh's place is the only one to which we can refer men for this one year of systematic work I have seen the men afterward, and they certainly are well prepared Especially is this true in regard to their surgical experience One very important point is that the men who know how to teach are not, as a rule, giving the time to teaching That is the trouble in this country so far as teaching and training men is concerned That is the reason so many men go abroad Dr Shambaugh touched on the point of training the individual man Put one or two men in your office That is the best preparatory training they can get I have been training men for fifteen years I do not take any man for less than two years, because I cannot give them a sufficient number of surgical cases in one year

DR CHARLES G STIVERS, Los Angeles Dr Shambaugh's excellent paper is devoted almost exclusively to the physical features of the otorhinolaryngologic side, and he deplores the lack of training in almost exclusively the surgical features of these organs We are given organs to use and the function of the organs of throat, mouth and nose is to be servants of the special senses Nothing has been said about the restoration of function after putting all these organs in proper condition I deplore the fact that thousands of men are doing ill advised and hasty operations on the nose and throat as I do the fact that they know nothing whatever about the restoration of function of these organs after operations have been done and I feel that any group instruction which fails to recognize that the function of these organs must be preserved and restored, after destructive surgery has been done, will fall short of its mission.

DR WENDELL C PHILLIPS, New York In his recent address before the Congress of American Physicians and Surgeons in Washington, Dr Frank Billings expressed the opinion that overspecialization in medicine was becoming a grievous sin in America, and there probably is more or less basis for such a criticism My own response to that statement is that there is overspecialization in America so far as pseudospecialists are concerned, but underspecialization so far as real specialists are concerned I have had considerable experience in graduate teaching I have thought seriously on this subject and this experience in teaching, together with a careful study of the whole problem of preparation of specialists in this country, has given me rather deep convictions on the subject Up to a few years ago the training that was considered the best for a young man to receive in order that he might know the field of specialism in diseases of the nose and throat was to secure an internship in one of the great special hospitals of the country, and in the Manhattan Eye Ear and Throat Hospital there has been a great demand for these positions We have eleven house staff positions and often fifty or sixty men apply The reason men seek these positions is that they furnish such unusual opportunity for acquiring the surgical technic of nose throat and ear operations It is very evident that in a hospital where nearly 1,000 patients come each day as outpatients where from thirty to sixty-five ether operations are performed daily, when a young man is inducted into that special work surgery occupies his entire time and thought One can see how he becomes imbued with the surgical side of it during his early years He serves his term in an institution of this kind, and becomes an expert in surgical procedure, but when he goes out into practice it takes him some years to acquire a knowledge of the basic principles of the subject, and he begins to feel the seriousness of the position in which he finds himself placed Dr Shambaugh has struck the keynote of the whole problem, and I wish that this section could go on record that any man who proposes to enter our specialty must first go through this basic training in the fundamentals of the work, learning the physiology, anatomy and other branches as Dr Shambaugh teaches them, and then after he has gone through that experience secure a position in a special hospital and learn the surgical part of it

DR CHARLES W RICHARDSON Washington, D C I have been associated for a number of years with this work of trying to find the best method for the education of specialists in otolaryngology Dr Shambaugh is the first one on that committee to be able to carry this work into practical trial and I do not know of any method that is better than that which he has adopted We have previously taught men backward We have been conducting them into the field of surgery and neglecting their proper clinical instruction by failing to give them the advantage of dispensary work In the special hospital of which I am a staff member, we insist that the interns work in the dispensary They can do a tonsillectomy, they can operate on the septum or on the sinuses, but take them to the dispensary and they do not know how to depress a tongue properly they cannot pass a catheter—they cannot do the ordinary, routine things necessary for diagnosis to say nothing of practical ordinary treatment When we see this we cannot praise Dr Shambaugh too much for his work in this line Another phase of the subject that is equally important is undergraduate teaching There is too much teaching of the young man in specialism In the universities the idea is that we are to teach medicine to the young men in the medical course, we are to make them general practitioners not specialists Any man who goes from the benches to specialism is a failure

DR M A GOLDSTEIN, St Louis The old men are essentially clinicians and diagnostic experts I subscribe to everything Dr Shambaugh said He is an altruist, and so am I I believe that his whole problem is ideal but in greater part it can be carried out practically I can count on my fingers

the men of the 'Old Guard" who are grounded in otolaryngology and in micropathology Everything in the discussion so far has tended to a consideration of the clinician, the diagnostician and the technical expert, but we must not lose sight of micropathology That is the fundamental basis on which we should build Dr Pierce, who has charge of the Casselberry prize fund, will tell you that there has not been an applicant for that honor A number of valuable prizes are offered by the three national organizations, but I think that on only one occasion has any prize been given for research work If we want to compete with the work done abroad we must ground not only our young men but also our old men, in the fundamentals and the fundamentals consist not only of clinical knowledge and diagnosis, but also of micropathology

DR NORVAL H PIERCE, Chicago I would not have you think that Dr Shambaugh's training of specialists is a makeshift affair I assure you that it is very much alive and practical He is doing very good work with somewhat limited facilities The whole proposition is founded on the fundamentals The advances in otolaryngology and the improvement of the practitioners of otolaryngology must come from their fundamental knowledge of the histology, the anatomy and physiology, normal and pathologic of these organs I think it is a mistake to divide the two—one-half fundamentals and the other half clinical I think it would be better to force a man to spend a given length of time on the fundamentals alone, before he takes up the clinical training The little details of office practice soon wear away the fervor of the otolaryngologist Unless one has intelligent training back of one unless one has the dreams of the laboratory to sustain one, one is bound to degenerate That sustaining imagination starts in the fundamentals, not in the taking out of tonsils and operating on septums If we are going to gain a place in medicine, it must be through research and investigation We have funds available, but no one makes any effort to win the prizes It is deplorable I do not believe I am wrong when I say that there has not been in this country a single case of otospongiosa or otosclerosis diagnosed during life that has been examined histologically We are fed from foreign sources We have become supine because of our lack of courage and training and, unless this is changed, I do not believe that we can maintain this quasiequilibrium that we have been maintaining for a few years past

DR JACQUES HOLINGER, Chicago The question of the education of specialists and advance of the science of anatomy, physiology and diseases of the ear, nose and throat is a question of money and of much money In order to make any real advance and do original work, especially laboratory work, to amount to anything three things are necessary a very large clinic with from 10 000 to 12,000 patients a year, a very large, first class laboratory and good connection with abundant postmortem material which can be had absolutely fresh Unless one can get these things together there is no possibility of starting on the fundamental training of specialists The one year course of Dr Shambaugh is very nice However, it will be admitted that instead of one year you could make it three or four years to go through all the phases of anatomy, physiology embryology clinic and laboratory work and the operating room You would come nearer to having specialists who are masters of their branch

DR. WILLIAM B CHAMBERLAIN, Cleveland I want to add my word of commendation to what Dr Shambaugh has said Two things confront one in the establishment of such a plant, first the proper care of the postgraduate student, and second the proper care and attention to the undergraduate student at the same time That is one point which Dr Shambaugh did not mention and which he has very well cared for In Class A schools while we are taking care of the postgraduate students we must not forget that we are also obligated to undergraduates, and the two cannot be confused I was glad to see that Dr Shambaugh laid such stress on the fact that the men were there six months before they were allowed in the operating room As many of the speakers have said, we have overstressed the technical part, the purely operative training I have maintained with my students for many years that the technical part of our specialty is the least We can take any good mechanic, any good machinist, any good carpenter, and make just as good an operating specialist as any of ourselves, but the development of the man in medicine and surgery with medical and surgical judgment is something far more difficult to obtain For years we have had a universal panacea for stupidity in Cleveland A visiting nurse examines a stupid child, and sends the child to the nose and throat clinic, his tonsils and adenoids are removed, and he is supposed to return to school one of the most brilliant pupils in his class Unfortunately, this does not hold true The diagnosis is made by the visiting nurse and the operation is done by the specialist under her direction It would be far wiser if the diagnosis could be made by the specialist and the operation performed by the visiting nurse Any Class A medical school can establish such a plant if it has the men with inspiration to do it The most difficult thing in our postgraduate schools is to provide suitable instructors Not that we do not have these men but the men who have the knowledge and the ability are not willing, or cannot afford, to spend the time, whereas in foreign clinics a large part of the annual stipend comes from association with students

DR GILBERT E SEEMAN Milwaukee I have been for some years interested in the medical school of the University of Wisconsin We now have the problem before us of completing our medical course and it is a gigantic problem, particularly in the matter of the adjustment of compensation It is our experience in the university that in the field of medicine outside the operative field, we have no very great problem in the matter of getting teachers, of obtaining adequately trained men to head departments, at the ordinary professorial salary But in those fields involving operative work it is our experience, first, that we have difficulty in getting young men adequately trained to take subordinate positions, and secondly that we cannot get experienced men who are willing to take the professorial salary and head the departments I think the reason largely lies in the trend in medicine and particularly in the field of otolaryngology It seems to me that in recent years it has developed into a matter of tonsil operations in most sections of this country Young men measure their success, and the success of all men, by the number of tonsils they remove, the number of submucous operations they do and not at all by the knowledge they have of anatomy and physiology I am very glad, indeed to hear an expression of sentiment deploring the condition which exists The men in this specialty have developed into tonsil operators and unless the trend is stayed by these older men in the specialty who have the authority to speak I believe that the specialty of otolaryngology will come on days that will be sad for those men who have tried to prepare themselves adequately in medicine and adequately as specialists in this field

DR GEORGE E SHAMBAUGH Chicago It is necessary, first of all that we arrive at a definite conclusion as to what we should strive for in the matter of preparing men for special practice What we are advocating for a proper basis for training is the plan that has been accepted as a proper basis for training abroad for many years The courses which were provided American students abroad were not the courses which their own men took in getting their preparation They followed the method which I am advocating namely, serving a period as clinical assistant in a properly conducted department where each man worked out his own salvation This cannot be accomplished by sitting on benches and listening to some one tell how he did the work No better illustration of the necessity in this country for more training in diagnoses before men are taught operative technic can be found than the statistics given in the paper just read by Dr New wherein patients had been subjected to operations repeatedly under circumstances in which any properly trained specialist could tell them at once that such operations were entirely useless I emphasize that too many men limit their prepara-

tions to acquiring some operative skill without any proper knowledge of the proper indications for operation The desirability of stimulating research work has been emphasized by several speakers This is a very important matter I am inclined to think that this result will best be accomplished by the establishment of fellowships which will make it possible for younger men who have completed one or two years of this special training to continue advanced work there a year or more With the long period of medical training now required, unless some special assistance is provided in this way most men are forced to devote their entire time to the problem of making a living

TUBERCULOSIS AMONG THE EX-SERVICE MEN

WITH A SPECIAL REFERENCE TO ITS BEARING ON PUBLIC HEALTH *

HUGH S CUMMING M D
Surgeon General United States Public Health Service
WASHINGTON, D C

A general impression apparently prevails among the laity that the incidence of tuberculosis was greatly increased in the United States by the World War It is not surprising that this idea is current Care of the disabled has naturally been a matter of general solicitude Difficulties encountered in providing sanatorium treatment were given wide publicity and sometimes exaggerated Moreover, the appalling increase in tuberculosis which occurred during the war in most countries of Europe, and which still prevails in Austria and Russia, has become common knowledge Among all those nations, including some nonbelligerents, whose food supplies were seriously affected and which felt keenly the stress of war and its results, tuberculosis increased, indeed to an alarming extent It is natural therefore although this country was fortunately spared the pinch of famine, the desolation of invasion and many of the fears, griefs, deprivations and other forms of stress which try the spirit, waste the body and therefore predispose to tuberculosis, that our citizenry should anticipate an increase of tuberculosis here and in the same pride with which they demanded a place in the fighting line, count their casualties in kind

It may be recalled that in 1919, when making a forecast of hospital needs, it was estimated by the Public Health Service that approximately 12 000 beds would be required within two years for tuberculous veterans It is also a fact that by the end of April, 1922, there were 11,346 tuberculous veterans hospitalized at government expense in the United States, as well as considerable numbers receiving compensation for that disability who declined hospital care The incidence of tuberculosis was, however, only slightly increased in the United States during the war, either among males of military age or any other class of population The forecast of hospital needs referred to above, which has proved to be approximately correct, was made merely in accordance with the known incidence of tuberculosis among the general population in the age groups concerned A glance at the curve (Fig 1) shows how sensitive the tuberculosis mortality is to collateral influences The slight but perceptible rise in 1916 and 1917 is presumably due to the increase in living costs or perhaps, more exactly, the degree to which this increase exceeded that in wages or other rewards for production To these causes must be added in 1918 that of the epidemic of influenza There seems little doubt that these increases were not related to actual participation in the war

The curve (Fig 2) comparing the mortality rates of 1915 and 1920 shows a marked postwar decline in tuberculosis mortality which is even more marked among males, including those of military age, than among females It is, I think, generally accepted that the incidence of tuberculosis in any country, in both sexes and at every age except infancy and childhood alone, reflects with great precision the living and industrial conditions prevailing It is therefore not strange that tuberculosis was not increased among our troops, who were generally well fed, well housed, and well clothed, or, except to a very slight degree, among the population as a whole

The War Risk Insurance Act of Oct 6, 1917, promised hospital care to disabled veterans, but made no provisions for the construction or operation of hospitals, nor did it name the agency whereby the proposed care was to be provided It was, of course impossible to reckon at that time with the desire which manifested itself as soon as the armistice was signed for discharge from military and naval service This prevented extensive use of military and naval hospitals for discharged men, who usually evidenced a distaste for all things connected with military life It was a perfectly natural reaction, considering the psychology of the situation and one which in no way reflects upon the excellent treatment provided by the Navy and Army hospitals

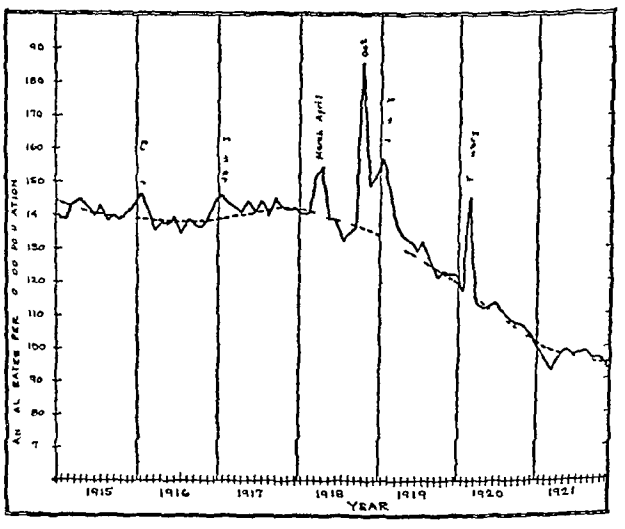

Fig 1.—Recent decline in mortality from all forms of tuberculosis monthly rates from 1915 to 1921 in twenty four states (in 1921 provisional data for only fifteen states were available) normal seasonal variation having been eliminated

It was not, therefore, until March 3, 1919, that by act of Congress the Public Health Service was named as the principal agency whereby hospital and medical care was to be provided The emergency was serious To place a properly trained physician in each city or large town in all parts of the United States, to find hospital beds for the widely scattered disabled veterans who applied for examination and treatment in all parts of the United States, and to equip, man and operate

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

such institutions in various parts of the country as could be converted to hospital use—these were some of the urgent problems that arose The tuberculosis patients caused considerable concern, and it was early apparent that the emergency hospital provision was at once necessary Congress, in failing to act favorably on the recommendations contained in House Document 481, which was transmitted by the Secretary of the Treasury, Dec 8, 1919, reflected the idea, not wholly extinct among medical men that permanent hospitals are not necessary for the treatment of tuberculosis The estimates made in House Document 481 provided for the construction among other institutions, of nineteen hospitals for tuberculosis with an aggregate capacity of 9,330 beds, at an approximate cost of $32,500,000 This was for tuberculosis hospitals alone The plan contemplated the construction of permanent institutions located near the centers of population to be served It

* Specific death rates per hundred thousand for males and female compared for 1915 and 1920 in twenty four registration states with percentages of decrease on revised intercensal population estimates for July 1 1915 and July 1 1920 but using the 1910 sex and age distribution The twenty four states are those constituting the death registration area in 1910 Acknowledgments are made to Dr W H Davis Chief Statistician for Vital Statistics Bureau of the Census for the use of mortality data from original tabulation sheets

visioned ample grounds with lawns and trees, and restful environments in salubrious but not isolated places Unfortunately, however the treatment of tuberculosis became associated in its early history with the tent, the shack, the lean-to with life in the open under primitive conditions The early advice, "Go West, and rough it," was recalled It was necessary to explain again and again that a tuberculous patient needs highly specialized care, calling for modern hospital facilities It was necessary for this conviction to find place gradually and for public sentiment to lead the way to the necessary appropriations

As an evidence of the difficulties encountered at one critical period, it may be mentioned that on Dec 24, 1919, the President approved the amendment to the War Risk Insurance Act, which increased the allowance for total temporary disability from $30 to $80 a month On the same day in anticipation of an increased number of claimants the Public Health Service solicited the assistance of the American Legion to find additional hospital accommodations for tuberculous patients believing that the criticism which the government was at that time facing might be in part ameliorated or its cause mitigated by concerted effort of the comrades of those needing treatment, to find hospitals suitable for their care The Legion, in response, sent out requests from its headquarters to posts in all parts of the United States, and its members cooperated with our field officers to the desired end A glance at the chart will show the extent to which contract hospitals were utilized in this very trying period We are all familiar with the

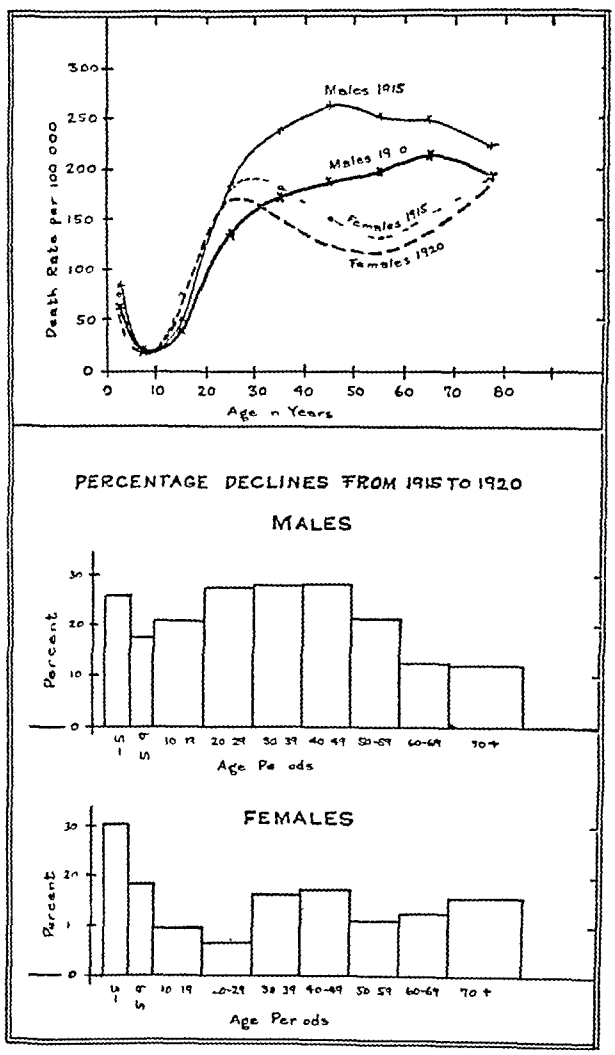

Fig 2—Specific death rates for all forms of tuberculosis in twenty four registration states compared for 1915 and 1920

criticisms which arose concerning their use I have no apologies to make The institutions were representative of the medical care prevailing in the respective communities at that time Some of the institutions were excellent Others were unsuitable, and these were abandoned as rapidly as their unsatisfactory condition was determined by the district inspectors detailed for the duty Whether it would have been better for the federal government to arrange with state sanatoriums and those operated by other political units for the care of all tuberculous patients in this manner is open to question The plan had many advocates among members of the National Tuberculosis Association A plan whereby such hospitals might have been enlarged by federal funds for tuberculous veterans was foredoomed to failure because of the distaste evidenced on every

hand to the admission of veterans to any hospital which cared for free patients, or, according to the vernacular, "charity patients" Objections were made to the use of state sanatoriums, county sanatoriums, and such excellent institutions as Oak Forest in Chicago, Seaview Hospital in New York City, and the Branch Hospital in Cincinnati There appeared, therefore, no choice but to proceed with the development of temporary hospitals for which some funds were provided but which, according to the law, could not be used for permanent construction

The character of the temporary army hospitals of the cantonment type is too well known to merit a description The widely separated, one story wards, the connecting corridors with numerous inclines, the numerous heating units, the fire risks, the difficulty of supplying hot food, are well known The sagging foundations, warped floors and leaky roofs of these temporary buildings were eloquent allies at a time when it was necessary to plead for new hospitals Some of the attacks made upon the government, notably in the case of the Fox Hills Hospital, were, possibly, not wholly devoid of a well-meant but ill-advised effort to force the appropriation of necessary funds to build permanent institutions

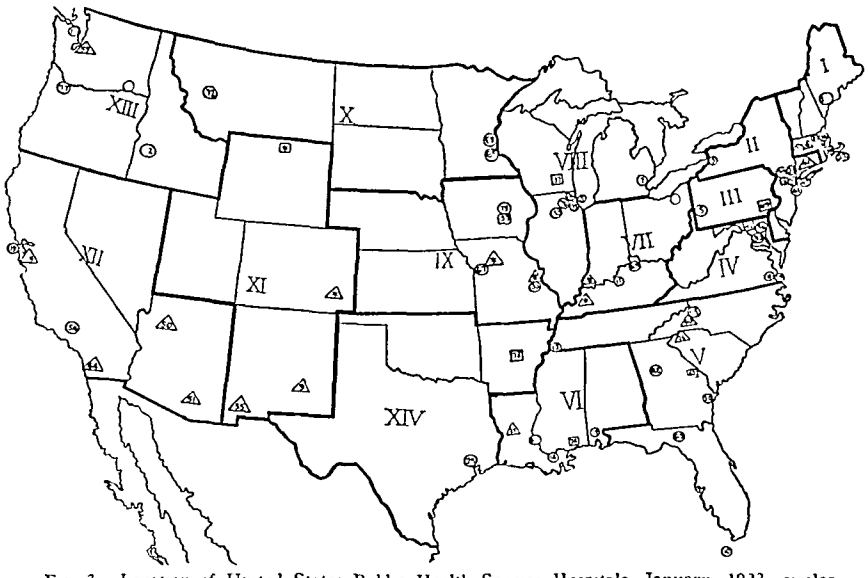

Fig 3—Location of United States Public Health Service Hospitals January 1922 circles indicate general hospitals triangles tuberculosis hospitals squares neuropsychiatric hospitals the numbers being definitely located in Table 3

The tuberculosis hospitals taken over from the Army, in addition to those at Markleton, Pa, and Deming, N M, which were abandoned as unsatisfactory as soon as more suitable hospitals had been obtained, were

No 24, Palo Alto, Calif, 650 beds
No 26, Greenville, S C 700 beds
No 27, Alexandria, La, 600 beds
No 41, New Haven, Conn, 500 beds
No 50 Prescott, Ariz, 765 beds
No 55, Fort Bayard, N M, 1,120 beds
No 60, Oteen, N C, 1,100 beds
No 64, Camp Kearney, Calif, 550 beds

To supplement these, a temporary hospital of 290 beds, intended chiefly for winter use, was established at Tucson, Ariz, at Pastime Park, cottages built from salvaged lumber supplementing the existing buildings The abandoned Indian School at Tacoma, Wash, was also converted into a temporary hospital of 278 beds

One of the difficulties in operating hospitals of this group was the lack of quarters for personnel The Public Health Service has a corps of commissioned officers, but lacks an enlisted personnel Its employees are all civilians who may leave at will and whose contentment is often conditioned on the presence of their families, of schools, social advantages, and other refinements of living not demanded or expected under military conditions From the patients' point of view it must also be admitted that the gloomy outlook afforded by the war time buildings, now four years old, is depressing

From the beginning of the work by the Public Health Service, the hospitalization and the transfer of patients was, so far as possible, decentralized A disabled soldier coming under observation at any point in the field and found to be in need of hospital care was immediately offered it, if not in one operated by the government, then in the best contract hospital available According to a custom which has prevailed in the Public Health Service for more than a hundred years, tuberculous patients are routinely admitted as a temporary measure to any of its general medical and surgical hospitals The tuberculosis wards in our hospitals in Boston, New York, Baltimore, Chicago and other large cities, which were important clearing stations, often contained several hundred patients each The tuberculous patients at Fox Hills indeed, sometimes outnumbered all others The resolution which the American Medical Association adopted at the Boston session last year, advocating this practice for civil hospitals, has served to disarm unjust criticism and to strengthen the government in a useful practice Your action therefore, wisely taken in the general interests of public health everywhere, has served the government in a trying administrative problem

The demand for climatic change was another heritage from an earlier generation Tuberculous patients and their friends demanded a transfer to special climates from northern, southern eastern, western and central portions of the United States The spirit of restlessness engendered by the war was manifest As a further evidence of this, a popular report is current that 25 000 tuberculous ex-soldiers are found to have migrated to Colorado alone, only 2 per cent of the hospital patients coming under observation in that state being natives of Colorado It was necessary to refuse many unwise requests for the removal of tuberculous patients, unsuited by reasons of physical condition, from hospitals where they were under treatment to other hospitals in the arid Southwest So far as I am aware, however, there are no instances in which a sick man in any part of the United States was not provided with or at least offered hospital care, of the standard prevailing in that community, without more than a few days' delay The most insistent demands were made for the transfer of terminal cases "Give this dying man a chance" was a frequent expression typical of the character of requests daily received It was exceedingly difficult and sometimes futile to attempt to explain

that the importance thus attributed to climatic influence is out of harmony with modern scientific thought, nor was the problem rendered easier by the fact that large numbers of reputable physicians throughout the country appeared to entertain views long since believed obsolete

The hospitals devoted to the care of veterans were manned almost exclusively by personnel from the military and naval forces Medical officers, nurses, reconstruction aides, dietitians and laboratory technicians were almost without exception with military experience, many of them having served overseas All, therefore, were well prepared to sympathize fully with the needs of their patients The American Legion is well represented in membership among both patients and personnel, and at some of the hospitals the local post constitutes the largest in the community, and sometimes the largest in the state

It need cause no surprise that special training in tuberculosis for officers was necessary The lack of adequate instruction in this specialty in most medical schools is well known, while the exclusion of tuberculous patients from general hospitals, a still all too common custom and the practice of sending tuberculous patients "away' have combined to alienate the average physician from a knowledge of tuberculosis The excellent Army schools in tuberculosis which were

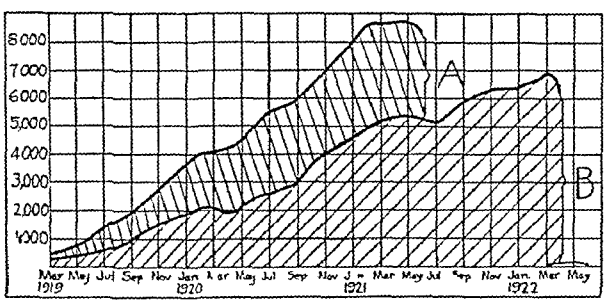

Fig 4—Hospital care of tuberculous veterans of the World War U S Public Health Service March 1919 to June 1922 patients in Army navy and soldiers home hospitals not included *A* contract and other institutions responsibility and control transferred to the U S Veterans Bureau June 1921 *B*, Public Health Service hospitals administration of veterans hospitals transferred to U S Veterans Bureau by executive order April 29 1922

conducted under the auspices of Col George E Bushnell, Retired, had trained a considerable number of Army medical officers some of whom continued on duty with the Public Health Service With these and a few other skilled men as a nucleus, the training of a sufficient number of medical officers was undertaken to provide proper care for patients in hospitals A summer school was conducted at Oteen, and numerous short courses in diagnosis held at various places, every tuberculosis hospital being required to give its medical personnel a prescribed course in training which during the last three years, has naturally been applied to a considerable number of medical officers stationed therein or assigned for the purpose Dr Palmer, who, together with Dr Boswell, has consented to discuss my subject, is one of the five experts who were engaged to visit our tuberculosis hospitals to assist in establishing a suitable standard of treatment and to strengthen weak points Since he visited more hospitals and visited them oftener than the others, he is perhaps better qualified than any other person to tell impartially, just as he told me in his official reports, the facts about the hospitals as he found them

It is not possible to tabulate the tuberculosis patients with respect to the stage of disease in which they were admitted, these figures not being available at the present time Many were admitted with doubtful diagnosis, claiming compensation for and giving a history of symptoms which indicated tuberculosis Some of these had been exposed to war gases or were convalescent from epidemic pneumonia In all, approximately 65,000 veterans were admitted to hospitals, including

TABLE 2—HOSPITAL ACTIVITIES OF PUBLIC HEALTH SERVICE

Note—The normal hospital operations of the Public Health Service in providing relief for merchant seamen and its other beneficiaries in the twenty five marine hospitals still remaining amounted last year (one year only) to the following

Old line patients admitted to hospital	44 756
Hospital relief days	1 191 171
Physical examination	79 750

both government and civil institutions, up to May 1 of this year It early become necessary to differentiate between patients having tuberculosis for which they required treatment and those with healed or quiescent tuberculosis which did not require hospital care Numbers of patients were discharged within a few weeks after admission, a board of properly qualified medical officers having determined that they were nontuberculous in a clinical sense

While final statistics have not been published, the general impression prevails that war gases were not an important cause of clinical tuberculosis In this

connection the following observation made by the Surgeon General of the Army in a recent report is pertinent "In the year 1918 there were one and one-half times as many cases of tuberculosis per thousand among all troops in France as there were among those gassed and in 1919 there were more than one and three-fourths times as many tuberculosis cases per thou-

sand among all troops as there were among the gassed troops"

The mental attitude of patients is indicated in some measure by the fact that out of 9,200 patients discharged from service hospitals between July 1, 1921, and May 1, 1922, 3,132, or more than one third, left against advice and without permission, treatment not having been completed Those discharged for disciplinary reasons during the same period numbered 189 Many of these patients, presumably, sought readmission to other hospitals in accordance with the spirit of unrest which still prevails, although to a less degree than formerly, among ex-service men The frequency of departures from the hospital against medical advice has been ascribed in part by experienced hospital executives to the custom whereby the Veterans' Bureau provides transportataion home for those so departing for the first time Homesick men, at some distance from their friends, and finding sanatorium regimen irksome, are tempted to take advantage of this opportunity to return to their families Men also who have at their own expense unwisely sought climatic treatment at distant places may enter the nearest government hospital, even for the express purpose of claiming transportation home It is somewhat significant that the small temporary hospital at Tucson, Ariz, with a capacity of less than 300 beds, discharged 488 against advice between March 15, 1920, and April 23, 1922, which is more than half of its total discharges during that period This hospital is one to which, with few exceptions, no transfers are made by the government, as it is merely an emergency hospital for ex-service men found in Tucson in need of medical care

Special treatments, including induced pneumothorax, heliotherapy, both natural and artificial, occupational therapy, including physiotherapy, and vocational training as applied therapeutic exercise, were encouraged in all the tuberculosis hospitals Some of the best results in tuberculous laryngitis were obtained at hospitals in the arid Southwest with sunlight and silence Some research work related to the presence of small pneumothorax as a common but hitherto unrecognized accompaniment of active pulmonary tuberculosis was carried out at New Haven by Surgeons Barlow and Thompson, the results of which will shortly be published as a bulletin of the Hygienic Laboratory The number of cases of bone and joint tuberculosis coming under observation has been rather surprising approximately 3 per cent of tuberculous patients admitted to hospital having nonpulmonary disease Of these, approximately two thirds had involvement of the bones and joints

Remembering that approximately one third of all veteran hospital patients are the tuberculous, an idea of the operations relating to this class may be obtained from the summary of the total hospital activities of the Public Health Service during the three years since the work was undertaken, given in Table 2

The medical work which the Public Health Service was called on to perform for the Bureau of War Risk Insurance and its successor, the U S Veterans' Bureau, is now history The field organization, including the fourteen district supervisors' offices and their subagencies reaching practically into every county of the United States, was turned over in June, 1921 The control of contract hospitals was relinquished also at that time The Veterans' Bureau, having further perfected its organization, finally felt itself ready to assume the administration of the veterans' hospitals which were accordingly turned over to Director Forbes by executive order, May 29, 1922 This transfer consisted of fifty-seven hospitals, with 17,500 beds, 13,057 patients (of whom 5,271 were tuberculous), and a personnel of 11,347, including 925 physicians and dentists, 1,425 nurses, 425 reconstruction aides, and 110 dietitians I take this occasion to pay public tribute, before a body which has ever honored fidelity, to the professional men and women who, having been identified with the organization and operation of these hospitals for many months during very trying periods, were transferred from the Public Health Service to the Veterans' Bureau for continued duty of the same character Their loyalty has been instant and unvarying, their patience untiring, their zeal unflagging, and their devotion unfailing in the cause of the disabled veteran and the government, whose obligations they strive to fulfil

ABSTRACT OF DISCUSSION

DR HENRY BOSWELL Sanatorium, Miss There are a number of tuberculous soldiers in this country, for the ex-soldiers are breaking down very rapidly I should like to emphasize that in the state of Mississippi, where we examine all soldiers and civilians, we are not having any more ex-soldiers with tuberculosis than we find in the civilians, of like age group With reference to the isolation of these men and their care we should try in every possible way to establish scientific institutions for the treatment of tuberculosis and to get out of the minds of the civilian population the idea that tuberculosis can be successfully handled in tents and shacks One certainly does not get results in tents and shacks About three years ago I made a survey of the institutions of North America in order to arrive at some solution of the problem I found that like institutions well built with scientific equipment got like results no matter where located, except in the state of Maine There, perhaps, the difference was due to the long period of cold weather The only other thing I should like to mention is the constant demand by the people on the medical profession to change soldiers from one place to another I remember one case which Dr Cummings paper brought to mind, in which we had considerable trouble in getting the patient's relatives to leave him with us He had an acute miliary tuberculosis His people succeeded in getting him transferred and he died on the train somewhere in Colorado before he reached Fort Bayard

DR H A PATTISON, New York Through the courtesy of Dr Cumming and the heads of other executive departments of the government, it has been the great opportunity and privilege of the National Tuberculosis Association to cooperate with the government in developing facilities for the care and treatment of tuberculous ex-service men As supervisor of the medical service of the national association, it has been my lot to do a considerable part of the work I had the opportunity to look into every corner of many of the Public Health Service sanatoriums, and of seeing how the Public Health Service found itself when, without adequate equipment, this great problem was forced on it Without adequate legislation physical equipment or sufficient appropriations thousands of sick men were thrown on it suddenly I should like to pay sincere tribute to the executive departments in Washington and to our medical and nursing friends in the hospitals for their devoted work in carrying on under great difficulties Before the congressional committee headed by Senator Walsh, I answered the question as to the reasons for these serious difficulties by saying that I considered them due to definitive and restrictive legislation The committee agreed with me, and the country was assured that very shortly Congress would dispose of that by legislation, making it possible to meet the situation As an example of the difficulty in the cantonment hospitals, take Palo Alto, Calif The California laws do not permit of the barring or screening of any windows even in one-story frame buildings It is therefore impossible to control the neuropsychiatric patients,

who have ready access to narcotic and liquor peddlers when their compensation checks arrive On the other hand, at Boise, Idaho, where there is better supervision, we have one of the best equipped and managed hospitals of this country in charge of the Public Health Service At Greenville, with an old broken down cantonment base hospital and the buildings painted in every conceivable color there was splendid morale and splendid work being done under the most adverse conditions The President recently transferred from the Public Health Service to the Veterans' Bureau about thirty nine hospitals The Veterans' Bureau has not had the hospital experience of the Public Health Service Only time will tell whether the Veterans' Bureau will go on with the splendid work the Public Health Service has been conducting, or whether we shall have just domiciliary care rather than real treatment

DR J J SINGER St Louis Dr Cumming brought out some very important points in relation to tuberculosis surveys of the general public In one of his charts he states that the adjusting of conditions is reflected in the mortality of tuberculosis This was very evident during the war period, at which time the death rate seemed to have diminished, though in the last few years it has somewhat increased The Public Health Service has brought out to my mind at least, and answers the question of whether tuberculosis is a medical disease or whether it is a public condition, a medical problem or a social problem I have seen a large number of cases diagnosed as tuberculosis and the patients given a pension of from $30 to $80 a month Those are the patients who have been doing well Those are the patients who have not gone out to work but have stayed at home or gone to private hospitals or physicians The strain of providing for themselves has been removed If the Public Health Service has done nothing else but this, its work is worth while The second point that the Public Health Service has brought out is the training of physicians in tuberculosis diagnosis To those working in tuberculosis it is generally recognized that early recognition must be done by the general practitioner The Public Health Service has turned out innumerable men all over the country who are trained in a tuberculosis clinic, and in that way they serve the cause

DR H S CUMMING Washington D C We have been trying to educate the average physician to the work in tuberculosis by establishing a school at Oteen N C I hope that the physicians will continue to be interested in one of the greatest public health measures

THE ANESTHETIC PROPERTIES OF PURE ETHER *

RAYMOND L STEHLE MA PHD
AND
WESLEY BOURNE MD CM
MONTREAL

At least twice within the last few years it has been reported that pure ethyl ether is not an anesthetic, and that the physiologic action ordinarily attributed to this compound is due to impurities contained in the commercial material According to Cotton,[1] carbon dioxid may be the active agent in some ethers, but this investigator reported that he had obtained the best results by the use of ether containing ethylene and possibly another gas of unrecognized nature According to Wallis and Hewer,[2] ketones are the most important impurities, though they state that the anesthetic action of ether is enhanced by treating it with carbon dioxid and ethylene The lack of chemical details in the papers of Cotton and of Wallis and Hewer is unsatisfactory

* From the Laboratory of Pharmacology McGill University
*The expenses of this investigation were borne in part by the James Cooper Endowment
1 Cotton J H Canadian M A J 7 769 (Sept) 1917
2 Wallis R L M and Hewer C L Lancet 1 1173 (June 4) 1921

The foregoing statements appeared to warrant further investigation All commercial ether today is manufactured by the Williamson sulphuric acid-alcohol process The reaction is such that side reactions may occur, the products of which may contaminate the main product and therefore lend some degree of plausibility to the claims mentioned A different method of preparing ether, therefore, was adopted Instead of the sulphuric acid process, a general reaction well known to

Fig 1—Details of Case 2

organic chemists was employed It consisted in bringing sodium ethylate and ethyl iodid together in alcoholic solution, whereupon the following reaction occurs

$$C_2H_5ONa + C_2H_5I = C_2H_5OC_2H_5 + NaI$$

The sodium iodid precipitates and the ether is separated from the alcohol by fractional distillation The possibility of side reactions occurring is not obvious, and the product may be assumed to be quite pure *A priori* the possibility of contamination with aldehyds and ketones is practically eliminated because, in preparing the sodium ethylate, the hydrogen generated

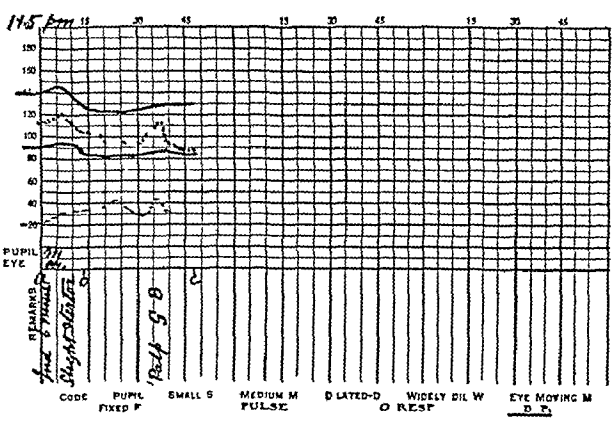

Fig 2 (back of card illustrated in Figure 1)—Curves of blood pressure heart rate and rate of respiration

when the metal was dissolved in the alcohol would have reduced any aldehyds and ketones present to alcohols In order to serve as a check, however, the ether obtained was analyzed quantitatively for ethylene while qualitative tests for aldehyds and ketones were performed

For the ethylene test, 2 c c of the ether in question was dissolved in tetrachlormethane, and 10 c c of an approximately third-normal bromin solution was added The mixture, in a stoppered bottle, was placed in the dark for eighteen hours to give opportunity for any ethylene present to absorb bromin At the end of

the reaction, the residual bromin was determined by titrating the mixture with a standard thiosulphate solution Assuming that all of the bromin not recovered was taken up by ethylene, the maximum amount which could have been present in the ether was 0 04 per cent It is likely that the amount was smaller than this, since some or all of the bromin may not have been taken up by ethylene, but may have substituted for hydrogen in the ether Schiff's test for aldehyds (restoration of red color to a fuchsin solution decolorized with sulphur dioxid) was negative, as was the nitroprussid test for acetone and for methyl ketones in general Other ketones than the methyl ketones do not give the nitroprussid reaction, but all of them are excluded because of their high boiling points (the simplest, diethyl ketone, boils at 103 C) They would have been eliminated in the fractionation process

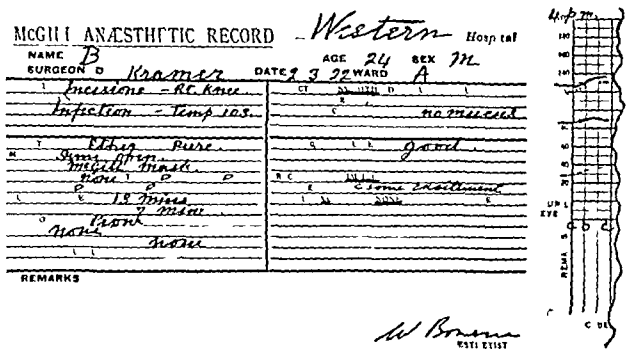

Fig 3 —Findings in Case 3

A small amount of ethyl iodid was present in the ether This was evident after exposing the product to bright sunlight for a few days, which caused it to take on a light amber color because of the liberation of iodin

Being satisfied that the ether prepared was suitable to decide the question at issue, we subjected its anesthetic properties to experiment An albino rat was the first object on which its action was tried When placed in a jar together with 1 c c of the ether, the animal became anesthetized almost immediately, and on removal from the jar recovered quite as fast as it had succumbed The remainder of the small quantity which was obtained in the preliminary trying out of the method of preparation was administered to a female

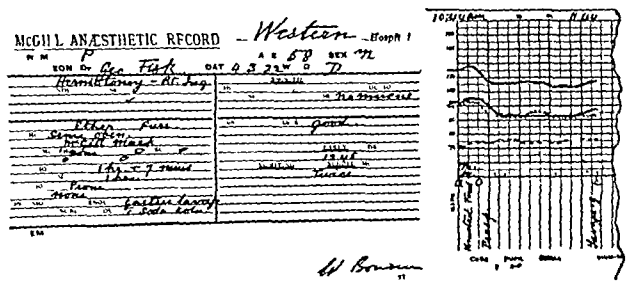

Fig 4 —Details of Case 4

patient weighing 245 pounds (111 kg) and being operated on for a large ventral hernia Induction took place in four minutes, that is, anesthesia was brought to the first stratum of the third stage This depth was maintained there ten minutes when, as we had no more of the material, a change was made to one of the commercial ethers

A larger quantity of the ether was then prepared (about 1½ pounds), and this was used in five additional cases which were chosen miscellaneously In none of them was there any preliminary alkaloidal medication, such as the administration of morphin and atropin The McGill modification of the Ferguson

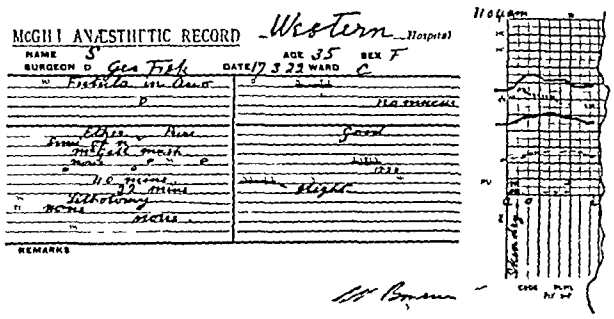

Fig 5 —Details of Case 5

mask was used All five patients expressed comfort during the induction period, which lasted from four to six minutes, and which was marked (except for a quite negligible amount of vomiting of food in Case 4 just before the start of the operation) by the absence of any signs of irritation, such as lacrimation, salivation, mucous formation, holding of the breath, coughing or struggling The whole period of anesthesia was uneventful in each instance and entirely satisfactory to the surgeon conducting the operation Recovery was immediate or early, and nausea and vomiting were minimal, even though gastric lavage was done only in the case of Patient 4 Worthy of mention is Case 6, in which good analgesia was obtained intermittently for each pain over a period of forty minutes of normal labor

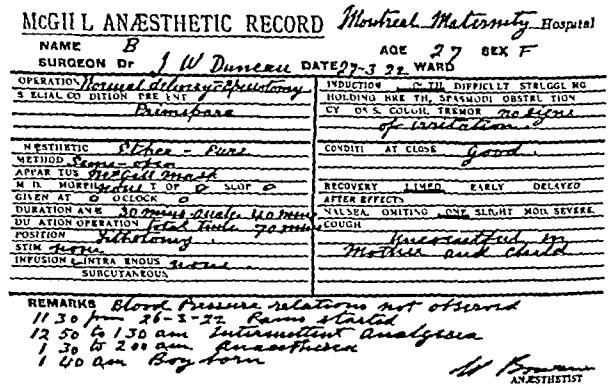

Fig 6 —Details of Case 6 The blood pressure relations were not observed

CONCLUSIONS

Pure ether, made by a clean-cut chemical reaction which excludes almost completely any contamination with substances which have been claimed to be the real anesthetic agents of ordinary ether, possesses to the highest degree the anesthetic properties which have usually been attributed to it

Recent Literature on Cancer of the Eye—M Manheimer reviews the literature of the last ten years on malignant tumors of the eye in the *Zeitschrift fur Krebsforschung* **18** 1, 1921, a total of 586 bibliographic references with titles The tumors are classified under twenty-one headings according to the location The list contains several congenital orbital sarcomas, one bilateral

MASTOIDITIS HYPERPLASTICA SEROSA*

J. W. JERVEY, M.D.
GREENVILLE, S. C.

There exists a certain pathologic condition of the mastoid which, up to this time, has not been recognized. The mastoiditis of the textbooks and of current medical literature of the world, for thirty years past at least, is an infective process, always accompanied by pus formation and, inferentially, of some specific bacillary origin. I believe that there is another and quite distinct type of mastoid disease.

It is well known that there exists a "serous labyrinthitis", why not a "serous mastoiditis?" The existence, not rare, of a "hyperplastic sinusitis" is an accepted fact, why not a "hyperplastic mastoiditis?"

Not to go into a prolonged discussion of the latter type, for instance, hyperplastic ethmoiditis, it is enough to say that more might be known of its etiology and pathology. It may exist in association with an interstitial and intracellular serous exudate, or it may not. In the mastoid structure, the two types can and do exist simultaneously.

It has been shown that in hyperplastic sinusitis there is a definite osteoporosis (Skillern). In the type of mastoiditis that I am reporting, this condition is macroscopically evident. The pain and congestion present in either case are doubtless due both to the bone cell spread and the pressure of the serous exudate. The functional disturbances may be attributed to the same cause.

Briefly, we may be confronted with the following syndrome, in whole or in part: impairment of hearing, gradual or recent, vague pains in and about the ear, parietal headache, mild nervous unbalance, and a sense of "bubbling" deep in the ear at intervals, which is quite different from the "popping" and "crackling," so often complained of when mucus is present in the eustachian tubes.

On examination, we find some or all of the following manifestations: mastoid tenderness on deep pressure, lack of temperature changes, a varying degree of redness and thickening of a crescentic area of the posterosuperior margin of the membrana tympani, perhaps accompanied by more or less sagging of the contiguous canal wall, excessive tenderness in the roof of the external canal, occasionally, drops of serous exudate seen in the middle ear through the transparent membrana tympani, lack of evidence of previous middle ear disease, a markedly reduced sense of hearing, a negative Rinne reaction, a normal blood count, lack of evidence of existing infection, and patent eustachian tubes. The discomfort and the loss of hearing (say to the point of hearing a watch on contact) demand relief. The patient's vocation (such as stenography or teaching) may be seriously interfered with. What is to be done?

In such cases, I believe roentgenology is our safest diagnostic guide. The roentgenogram will show marked thickening and blurring, but unbroken continuity, of the mastoid cell walls, and the bony wall of the lateral sinus, with slight haziness of the whole affected area. This picture can with a little difficulty be distinguished from the cloudiness and the broken down cell walls of a purulent infection, as well as from the picture of a partially sclerotic process. Curiously enough, Law's masterwork on roentgenolcgy of the mastoids fails to note this type of pathology.

On operation, the findings are characteristic and unmistakable. The mastoid cells are filled with clear yellowish serum, the cell walls are noticeably thickened and evidence extensive osteoporosis, the antrum may be filled with the same serous exudate, smears and cultures of this exudate are microscopically negative.

It has been suggested to me that if the mastoid cells and antrum were filled with fluid, the middle ear also will necessarily be filled. This, of course, is not true. It is a simple physical fact that the mastoid and antrum, constituting a cavity closed except at its tympanic opening, would not discharge any liquid contents into the lower lying cavity until supersecretion forced the contents out, drop by drop. Hence, the phenomena observed and reported above. The drops which are forced out cause the "bubbling" hearing sensations, and these drops may be either absorbed in the middle ear as fast as deposited there, or milked out through the eustachian tube in the course of its physiologic functioning.

There is little or no reaction from operation, the wound may safely be closed, recovery is uneventful, and hearing is restored in whole or in part.

Macroscopically, the pathologic condition appears to be of a hyperplastic, serous nature, hence the title of this article. I regret that microscopic examination of the exenterated material cannot be reported. I have observed three or four cases of this character (and have one under observation, not operated on at this writing), but not until the last operation did I realize that the condition was one hitherto unrecognized, or at least undescribed in recent literature.

As to the etiology, at this time we may conveniently take refuge behind a word that may cover much territory and a multitude of sins—and say that it is cryptogenic. But we may properly theorize, briefly. I have said that the disease presents no evidence of infection. But this fact does not preclude the possibility of the deposition of long previous infection, with an exhibition of ultimate effects—the infection and its ultimata being worn to a state of unrecognizable attenuation by time and the old fashioned *vis resistentiae naturae*. I have heard earnest students of pathology make the statement that they could not conceive of hyperplastic tissue degeneration without the existence of previous infection, whether exogenous or hematogenous as related to the affected part. I must admit, too, that I have more than once seen the two types (serous hyperplastic and infective) existent at the same time in one mastoid, viz. the subcortical cells showing the serous type, and the cells immediately adjoining the antrum, and the antrum itself, filled with pus. Of course, many of you must have observed these things, but they seem to have hitherto escaped publication.

In discussing the mastoid changes following chronic middle ear infection, so great an observer and authority as Politzer[1] speaks of proliferation of cell lining membrane, eburnation of process, granular osteitis and caries, cholesteatoma, hyperostosis and osteosclerosis, but makes no mention of serous exudate, tissue hyperplasia and osteoporosis such as we have here under consideration. This fact necessarily lends weight to the tentative hypothesis that the latter conditions are not the sequelae of chronic infection while

1. Politzer: Textbook of Diseases of the Ear, translated by Ballin and Heller, 1902.

evidently, and of course, they are certainly not manifestations of an acute sepsis

While one cannot deny the indubitable possibility of previous infection in these hyperplastic cases, I like to think of them as something new, something different, and I should like to suggest that, for the present at least, and until more is learned about them, they be classed etiologically as of the so-called "deficiency diseases," meaning that general class of morbid metabolistic variations produced by dietary insufficiency, perhaps by some lack of vitamin ingestion, such as has been suggested by Kauffman [2] as the possible causation of hyperplastic ethmoiditis and otosclerosis

The prognosis seems to be good The simple mastoid operation, thoroughly done, has resulted, and theoretically should result, in clearing up or at least greatly ameliorating the symptoms And, in this day and time, one would hardly say that a simple mastoid exenteration, in reasonably skilful hands, could be regarded as a very formidable procedure

Following is a brief abstract of the salient points of a case illustrating the foregoing observations

REPORT OF CASE

Miss L H, white, aged 49 stenographer, first seen Jan 9, 1922 one week before consulting me had had severe pain in the left ear and the left side of the head This had been more or less continuous There were occasional "bubbling" sounds in the ear

Disregarding some slight abnormalities in nose and throat the left membrana tympani was mildly congested, with special reference to the long handle of the malleus and Shrapnell's membrane The posterosuperior wall of the canal and the contiguous portion of the membrana were noticeably sagging There was no visible perforation There was marked tenderness on deep pressure toward the mastoid tip On the right, the patient could hear a watch at from 4 to 5 inches (10 to 12 5 cm) and Rinne's reaction was positive On the left the watch was heard on contact and Rinne's reaction negative The temperature was 97 8 F, the pulse, 88 Urinalysis revealed a trace of albumin

January 10 The blood count showed white cells, 7,600, polymorphonuclears, 64 per cent Roentgenograms revealed the right mastoid sclerotic throughout the large portion, with a large tip cell, the left mastoid showed cells external to the antrum and those in the anterior half of the tip cloudy with thickening but no breaking down of cell walls To a less extent the same conditions were noted over the sinus area, and the bony sinus wall was very much thickened throughout its mastoid course while its appearance before entering the mastoid process was thin, well marked and distinct

January 11 The pain continued in the left ear and left side of the head The sagging of the posterosuperior canal wall was marked The temperature remained normal There seemed to be little doubt that there was an inflammatory process going on in the mastoid, but it seemed doubtful that there was any pus present The hearing was badly affected and this distressed the patient

Virtually the same observations continued for the ensuing week January 18, the mastoid was opened and the following observations were recorded Cortex of average thickness, cells filled with clear serous somewhat sticky fluid, cell walls noticeably thickened and showing a marked macroscopic picture of osteoporosis The antrum was filled with the same clear viscid secretion, with no evidence of disease in the antral lining or walls, and no evidence of pus in the entire field The smears and culture from the secretion were microscopically negative for bacteria The wound was entirely closed and healed by first intention

January 21 The patient was able to hear the watch through the bandage

January 23 The healing was complete, and dressings were discontinued The congestion in the deep canal was noticeably less, and the patient was able to hear a watch at 4 inches (10 cm) She was dismissed and sent home

January 25 A card, dated January 24, was received from the patient, saying "I can hear the clock in my room ticking! Gratefully yours"

February 11 The patient felt well, said that hearing was 'ever so much better", and she was back at work She can now hear a watch at 8 inches (20 cm) The membrane and canal appeared normal

COMMENT

This case was so striking that my hitherto hebetudinous mentality began, however weakly, to function, and, in looking over my records, I found at least four other mastoids which had come to operation presenting much the same characteristics Belated inquiry then, with the assistance of the American Institute of Medicine, led me to the at least tentative finding that this was a type of mastoid disease hitherto unrecognized, or rather unreported in the literature, although evidently of considerable pathologic, and I may say economic importance

Jervey-Jordan Building

ABSTRACT OF DISCUSSION

DR J A STUCKY, Lexington Ky A young woman, aged 19, had all the symptoms described by Dr Jervey I had seen her a number of times when she was suffering this intense pain I sent her to Dr C R Holmes with a note stating that I thought this was a hysterical case He sent her back with the statement that he did not think it was hysterical, that I had better operate I did not do so for several weeks afterward In the meantime, the patient suffered severe pain There was nothing to indicate the real pathologic condition, but she had all of the symptoms described by the essayist When I opened the mastoid, I found a normal condition with the exception of serum in the bottom of the lower cells I closed the wound with blood clot and the woman was entirely relieved She made a rapid and uneventful recovery But the strangest thing about this case is what happened six months afterward She demanded an operation on the other ear I had never had a patient come to me for a second mastoid operation I had looked for every focus of infection I had eliminated toxemia and acidosis When I opened this mastoid I found the same condition of affairs as in the ear operated on previously I took a culture from the cells in which I found this exudate, and the pathologist reported it negative I have seen one other such case I do not know how to classify them but I have labeled them 'freak mastoids" I regard them as hysterical cases

DR ARNOLD B KAUFFMAN Chicago I was very much interested in the suggestion Dr Jervey made as to the possible etiology of the condition he describes During the past year, in the clinic of Drs Beck and Pollock, we studied the possible relationship of dietary deficiencies to various nasal and aural conditions (otosclerosis, hyperplastic ethmoiditis) which were particularly of more or less unknown etiology, and which pathologically showed changes not of an inflammatory nature nor directly due to bacterial invasion We called attention to the bony changes in the temporal bone in rickets The presence of osteoid tissue is well marked, the newly formed bony tissue is uncalcified and covered with osteoblasts We believe, then, that we can assume as a working hypothesis that a similar deficiency acting throughout a different period of life may not produce such a clear cut disorder as in infantile rickets, but certainly may produce bony changes elsewhere

DR NORVAL H PIERCE, Chicago I am inclined to think that Dr Jervey's case and Dr Stucky's are explained best by a peculiarity of the mucous membrane lining the cells of the mastoid, rather than by any infectious micro-

2 Kauffman A B Laryngoscope 32 50 55 (Jan) 1922

organism, or by deficiency disease, or any other thing that might be suggested These cases do occur—I have seen them myself—in which there is arrested pneumatization When we speak of arrested pneumatization, attention is focused on the bone, when, as a matter of fact, the most important factor is the mucous membrane In all of these cases of arrested pneumatization, which always dates back to the second or third year of life, there is a mucous membrane which is thicker than normal and which is covered by an abnormal kind of epithelium The thickness of the mucous membrane is due to presence of the myxomatous embryologic tissue which entirely fills up the cavum and antrum during the latter months of fetal life This arrested pneumatization may be complete or incomplete There is a dark area within a whitish area which shows the internal auditory canal in the petrous portion of the temporal base, and a rather dark line which indicates the anterior part of the sinus and between these are cells more or less complete and more or less normally arranged Normally the peripheral cells are larger than the central cells There may be more cells than this, they may run to the tip, but I think you will invariably find in these cases that there is not a completely pneumatized mastoid When we see this in the roentgenogram, we may rest assured that there is a peculiarity of the mucous membrane, and that peculiarity is that it is thicker, owing to the presence of the embryologic tissue This type of mucosa has a low degree of resistance and a peculiar reaction to bacterial infection, which produces just such cases as Dr Jervey has outlined sometimes with very great pain and yet with no destruction of bone and no expression of pus but of serous exudate They rarely require operation

DR GEORGE E SHAMBAUGH, Chicago I am trying to get clearly in mind just what Dr Jervey considered were indications for operative interference It apparently was not the fear of a defect in the hearing developing as the result of a persisting discharge through the middle ear, because there has been no evidence of secretion in the middle ear Was it the revelation of the roentgenogram? A shadow over the mastoid gives no indication that there is the sort of process going on here that requires surgical intervention Was it discomfort in the region of the mastoid that led him to operate? It is a very common thing, if we take the pains in all cases to look for it, to find distinct evidence of mastoiditis in cases of acute otitis media It is however, the unusual case of acute mastoiditis that really calls for operative intervention A shadow simply means that the pneumatic spaces of the mastoid are filled with a pathologic secretion This much we can determine by other tests for example transillumination or the presence of tenderness over the process itself may reveal the condition This is no indication for operative intervention It is only when there is a persisting discharge for a number of weeks, or when after several weeks' discharge, the roentgen ray reveals a distinct area of softening that a surgical opening of the mastoid is indicated except, of course, in those cases in which because of some complication, sinus thrombosis unusual high temperature or persisting severe pain one may be called to operate

DR LOUIS K GUGGENHEIM, St Louis I agree with Dr Shambaugh's argument against a mastoid operation unless there is an absolute indication In St Louis, when we read of the number of mastoid operations performed east of the Mississippi, we feel that we are either ultraconservative or behind the times for we perform but few mastoid operations

DR J W JERVEY Greenville S C Dr Shambaugh says he does not quite understand what I consider indications for operation I thought I had quite sufficient indications inasmuch as the patient had a very marked troublesome and partly incapacitating impairment of hearing If there was any chance for improvement of hearing, she was certainly entitled to the chance However, that alone would not have been sufficient indication for operating, but she had a marked deep tenderness in the mastoid area, particularly above the tip, she also had a constant and severe pain, which had been present for at least two weeks Something had to be done to relieve that In addition, we had the roentgenograms of the mastoid, which in her case we thought quite distinctive It certainly showed a condition we had not seen before, the characteristics being thickening of the cell walls and of the lateral sinus wall, which turned out to be an osteoporosis A leukocyte count was made and a Wassermann test, and smears and a culture were taken, all with negative results, as stated in the paper

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION W A PUCKNER, SECRETARY

ALBUMIN MILK-HOOS—Dry Protein Milk—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content Each 100 Gm contains, approximately, protein, 30 Gm , butter fat, 25 Gm , milk sugar 15 Gm , ash, 4 Gm, and small amounts of free lactic acid

Actions and Uses—When suitably mixed with water, albumin milk Hoos is said to be useful for correcting intestinal disorders of infants and children

Dosage—For the majority of conditions, albumin milk-Hoos should be administered in small quantities according to age and condition of the patient, after a period of starvation of from twelve to forty-eight hours Suitable carbohydrates may gradually be added to the preparation as indicated by the clinical conditions

For use the contents of one small package of albumin milk Hoos (3 ounces) are sprinkled on the surface of 1 quart of warm previously boiled water, and the mixture is beaten with an egg beater or wire whip After mixing, the product is poured twice through a fine strainer the curds being rubbed through with a spoon Greater dilutions are sometimes prescribed Carbohydrates, if prescribed, are dissolved in a little warm water and added to the mixture The finished product contains approximately 3 16 per cent of protein 2 41 per cent of fat, 1 83 per cent of lactose and 0 41 per cent of ash

SPIROCHETURIA

The path of invasion which micro-organisms follow in the body seems to be understood better at present than are the courses by which they are disseminated and the places of exit which they sometimes find An organism may grow locally and produce few if any other than local manifestations, again, although confined to a limited focus, it may produce a toxin that is distributed readily through the circulation so as to initiate serious remote effects In still other cases the micro-organisms invade the lymphatics or the blood stream and thus become widespread Bacteremia arises in this way Many factors are known to act against the entrance of bacteria into the body, and it appears that organisms often find it equally difficult to emerge from their hiding places The elimination of some species with the stools has long been recognized, as in the case of dysentery and cholera In other instances, such as typhoid and tuberculosis, the responsible bacilli frequently are found in the urine

The fate of the spirochetes in this respect has only lately come into especial prominence Since the discovery, in 1915, that Weil's disease is caused by a specific micro-organism, *Spirochaeta icterohaemorrhagiae*, the excretion of the spirochetes by the kidneys has been shown by successful transmission of the disease through inoculations of urine from infected animals and patients In fact, the micro-organism has since been discovered to occur in many organs and tissues during icterogenic spirochetosis Warthin [1] of the University of Michigan has demonstrated that the elimination of the organism of syphilis, *Spirochaeta pallida*, may take place under the same conditions and apparently with the same mechanism as described for the spirocheturia of infectious jaundice There is a more or less generalized spirochetosis in the body, with spirochetemia In the kidney there occurs a massing of the spirochetes about the convoluted tubules and a passage of the organisms from the vessels and interstitial tissues into the tubules, where they undergo disintegration for the greater part This destruction of the organisms in the kidneys is more marked in the case of syphilis than in infectious jaundice

According to Warthin, the elimination of spirochetes through the kidneys, with the production of associated renal lesions, appears to constitute a family characteristic for the entire group of spirochetal infections, so far as the known types of the organisms have been studied carefully In infectious jaundice, the spirocheturia is a factor of considerable diagnostic value The Michigan observations are not the first to be made in regard to the spirocheturia of syphilis, but they are probably the most convincing demonstrations of the excretion of *Spirochaeta pallida* through the kidneys in man Warthin has pointed out that syphilitic spirocheturia occurs in the stage of septicemic syphilis, in both the congenital and the acquired infections *Spirochaeta pallida*, as is *Spirochaeta icterohaemorrhagiae*, may be excreted in enormous numbers through the convoluted tubules During such excretion through the kidneys, Warthin concludes, the spirochete of syphilis suffers greater destruction than does the icterogenic parasite, so that fewer spirochetes may reach the urine in syphilis than in infectious jaundice The demonstration of the occurrence of syphilitic spirocheturia, therefore, is not likely to possess such diagnostic value as that of icterogenic spirocheturia

THE IMMUNIZATION OF NURSES TO DIPHTHERIA

In the case of diphtheria, the efficacy of modern medicine has been put on trial, so to speak, to a degree perhaps not emphasized equally with respect to any other disease regarding which great advances in our knowledge have been recorded The bacteria and other elements in the causation of diphtheria have become familiar to both physician and layman The recognition of the nature of the immunity conferred by an attack from the malady remains among the great discoveries of scientific investigation The production of immune serums and their gradual refinement are triumphs of the laboratory that have not only challenged admiration but also conferred untold benefits on mankind by curing diphtheria beyond the hopes of an earlier generation Then came the unexpected finding of the menace of the widely distributed carriers, themselves immune, yet omnipresent dangers to the environment in which they tarry Finally—for the moment—we may record the application of the Schick or analogous tests to determine the existence of susceptibility or immunity in the individual coupled with the attempts at immunization by the use of diphtheria toxin-antitoxin mixtures

To those who have lived through this history of the investigation of the cause and management of diph-

theria, it seems like a long story in which discouragement has always been succeeded by discoveries of great promise Despite the lowered mortality due directly to the administration of antitoxin, there is still a large incidence of diphtheria to which the intolerant and the pessimist continue to point with ill concealed satisfaction in their challenge of the advantages of modern science In the larger cities, diphtheria remains endemic, and each year there still is a large morbidity It has become obvious to students of preventive medicine, therefore, that the next step forward must be in the direction of securing a greater immunity among our population Since the percentage of positive Schick tests usually given for adults is considerably lower than that found in children, attention has been focused primarily on the latter

The results of attempts at immunization of children, conducted on a sufficiently large scale to afford convincing statistics and controlled by repeated tests of the degree of success secured, have been decidedly encouraging [1] Among those persons most intimately exposed to diphtheritic infection are physicians and nurses It is gratifying to learn that for them, too, there is promise of successful active immunization following the practice of systematic administration of toxin-antitoxin mixtures to those who react to the Schick test Cooke [2] has reported the outcome of such a program for the susceptible training school nurses on duty in the Contagious Pavilion of the St Louis Children's Hospital, a group of young women showing an unusually high incidence of susceptibility There were 58 per cent of nonimmunes More than 80 per cent were immunized by the injections, the Schick test remaining persistently positive after two series of toxin-antitoxin injections in only a small number of the women

During the three years preceding the immunization, twenty nurses, or 28 per cent of those on duty in this contagious pavilion, developed diphtheria In the four years' period after the immunization was instituted, there was a decrease in the incidence of clinical diphtheria among these nurses of at least 90 per cent This is a triumph of preventive medicine If it is thus easy to protect an entire nursing staff from contracting diphtheria, by the use of the Schick test and toxin-antitoxin injections, one must agree with Cooke that this procedure should be carried out in all institutions caring for children

VITAMIN THEORIES

The essential experimental facts about the functions of the best known vitamins have become sufficiently familiar to justify the belief that these newly recognized food factors furnish something of importance in a human diet Holt [1] recently summarized the service which the newer knowledge has rendered by pointing out how it has helped to place the whole subject of nutrition on a better scientific basis The experimental has been substituted for the empiric method in determining the value of the different foods Formerly we might know that certain foods were desirable and necessary, now we are often able to say why such is the case and to determine their precise value in nutrition

The study of vitamins has helped to make clearer why a variety of foods is so essential to well being, and how danger may follow when diet becomes restricted from either necessity or caprice Decrying the indiscriminate use of alleged vitamin-bearing preparations as popular therapeutic agents, Holt further utters the warning that until they have been confirmed by adequate clinical experience there is some danger in relying too much on the results of laboratory observations on animals of a different species whose physiologic needs may be different from those of human beings In a somewhat similar strain, Mitchell [2] has asserted that in the total lack of quantitative data on the vitamin requirement of man, and in the general absence of malnutrition or disease among people in this country which can with any degree of probability be diagnosed as involving vitamin deficiencies, it seems premature to formulate recommendations for the balancing of diets with respect to vitamins It is pointed out that the classic experiments are conducted in each instance on species peculiarly susceptible to the particular deficiency under investigation However, this sort of criticism is a conventional one in medicine While admitting the background of truth in it, we must recall that the clues furnished by animal experimentation have led to so many helpful avenues of information that it would be scientific folly to fail to heed them, even in our as yet inadequate understanding of the possible bearing of vitamins on human welfare There is no necessary conflict between an open mind and conservatism in scientific judgment Hence we are glad to reiterate the warning of Mitchell, when he writes

> At a time when popular periodicals are widely publishing irresponsible articles on vitamins ignorantly or deliberately creating an entirely distorted popular conception of them, and when commercial concerns are widely advertising purely hypothetical advantages of vitamin preparations, it is particularly important that investigators in nutrition exert great care in the wording of statements as to the practical significance of vitamins in every day life Otherwise they may become unwilling accomplices in the perpetration of a gigantic fraud upon the American public

1 Holt L E The Practical Application of the Results of Vitamin Studies J A M A **79** 129 (July 8) 1922

2 Mitchell H H The Necessity of Balancing Dietaries with Respect to Vitamines Science **56** 34 (July 14) 1922

It is in harmony with such conservatism of statement, we believe, that the recent report of the Council on Pharmacy and Chemistry of the American Medical Association on yeast preparations has been formulated.[3]

With so much uncertainty still admitted, it might seem futile to discuss at this time the theories of the mode of action of vitamins. However, the history of science attests that its development has more often been promoted rather than retarded by the leavening influence of hypotheses. Most investigators of the vitamins have looked on them as functioning somewhat as hormones are supposed to act in the organism, namely, as stimulants to certain physiologic mechanisms. Others have imagined the newly discovered factors to be essential components of some, at least, of the living tissues, thus they would be quite as indispensable as are other structural units of the body, such as certain amino-acid groups, calcium, phosphorus or iron. A further group of students has assumed the vitamins to be primarily catalytic in function, thus behaving like the well known enzymes. Hess[4] of Zurich has lately offered somewhat indirect evidence that the antineuritic vitamin, which relieves the symptoms of polyneuritis in animals fed on diets devoid of vitamin B, contributes in some way to the production of oxidative enzymes in the body. Studies in vitro on the tissues of polyneuritic pigeons indicated to him a decrease in the oxidative enzymes usually found in well nourished animals. On this hypothesis the avitaminosis is an expression of poverty of the cells in the factors that facilitate tissue respiration. This is one of the many guesses which the future will need to evaluate in the physiology of vitamins.

THE FUNCTION OF BILE

The secretion and function of bile have long been a disturbing puzzle alike to physiologists and to clinicians, and in spite of many recent additions to our knowledge, there are still many unsolved problems. A critical review by Whipple[5] serves to indicate what has been determined and what is still to be learned concerning this important subject. Perhaps the most striking conclusion is that the entrance of at least a certain amount of bile into the intestine is necessary to life. We see patients survive so long with completely occluded bile tracts that the vital necessity of the bile has often been doubted, and physiologists have supported this doubt by observing that experimental animals seem to do very well when the bile is prevented from entering the bowel. Diet seems to be an important factor in this. For example, a fistula dog will usually die within two months with acute intestinal disturbance if kept on an ordinary diet of kitchen scraps. A diet of milk, cooked potatoes, rice and bread will prolong life considerably, and such dogs may live in good condition for from four to ten months and die with advanced bony abnormalities, osteoporosis resulting from the protracted loss of inorganic salts through the fistula. Abnormal pigment disturbances and true purpura with fatal hemorrhage may develop in such dogs. Addition of cooked liver to the foregoing diet will usually improve the condition and prolong the period of health in these fistula dogs, but they are likely to suffer at times from some of the conditions noted above. Bile fistula dogs with tiny fistulous tracts connecting with the duodenum may live for long periods in perfect health and function. The amount of bile gaining entrance to the duodenum is very small, and can scarcely exceed 10 or 20 per cent of the total flow which escapes through the external fistula. This shows how little bile may serve to change the entire clinical picture from abnormal to normal. The same amount of bile by mouth will not have any similar effect. Therefore it seems safe to conclude that secretion of bile into the intestine is necessary for normal health and even for actual continuation of life beyond a few months' period.

The use of cholagogues in medicine receives little support from experimental studies, for as far as can be learned the chief if not the only real cholagogue is whole bile or its active principle—that is, the bile acid fraction. The mere fact that drugs are claimed to be cholagogues by some and denied by others will indicate to the student of bile physiology that the cholagogue action is at least insignificant if not absent. Bile salts by mouth or intravenously will cause a distinct rise in the volume of bile secreted by a temporary or permanent fistula. Likewise, a meat diet favors an abundant flow of bile in a bile fistula dog, but a diet rich in carbohydrates, especially sugar, will decrease the bile flow under similar conditions. This shows the importance of diet as influencing the bile flow. None of the so-called cholagogues can be shown to produce the uniform and definite increase in bile flow that is given by bile feeding, and if they have any influence it is less than that produced by a meat diet.

We recently discussed the interesting studies of Rous and McMaster,[6] which demonstrated the remarkable power the gallbladder has to concentrate bile, reducing its volume as much as 90 per cent in twenty-four hours. This supports the old idea that the gallbladder serves as a reservoir of concentrated bile, to be poured out when needed, and clinical procedures have been devised on the theory that certain stimuli cause the gallbladder to contract and expel its contents into the duodenum, where it may be collected for analysis. But it is difficult to accept this view in the face of experiments

which show that dyes introduced into the gallbladder remain there as long as three days, and that the bile that enters the stimulated duodenum does not come from the gallbladder

Until recently it was generally believed that the bile pigments are all formed in the liver, and only in the liver, hence the dictum of "no jaundice without liver involvement" We now know that there do exist forms of hemolytic icterus with which the liver is not concerned and apparently the power to change hemoglobin into bile pigment is widely exhibited throughout the body Probably this is a general property of vascular and serous endothelium, and Whipple suggests that perhaps the particular activity of the liver in this process depends on its abundant supply of active endothelial tissue in the form of the Kupffer cells Certainly the liver is ordinarily the chief place in which bile pigments are formed, for injury to the liver depresses bile pigment excretion There is, in any event, no evidence that the bile pigments serve any useful purpose, and hence they may be regarded entirely as excreted waste products Nor has any value been ascribed to the cholesterol excreted in the bile, unless we look on the formation of gallstones as a useful function

Current Comment

ARTIFICIAL PNEUMOTHORAX TWO THOUSAND YEARS AGO

A knowledge of medical history is a most distressing thing, for it discloses persistently that this or the other new discovery is only a rediscovery We must take our consolation in the fact that generally the first steps were but halting ones, not being backed by sufficient force of actual knowledge to permit them to reach their goal, and hence our newer progress on a more substantial basis is, after all, the only worth while advance Krause[1] calls attention to the fact that Hippocrates described beyond a doubt the treatment of pulmonary disease, probably empyema, by the production of artificial pneumothorax, in these words "If this affection results from a wound or, as sometimes happens, from an incision for empyema, one should attach a pipe to a bladder, fill the bladder with air, and send the air into the interior of the chest And one should insert a solid pewter sound and push it forward It is by this method that you will get the very best results" While we are accustomed to date the inception of the idea of artificial pneumothorax from Forlanini's first work of forty years ago, it seems that it was well recognized more than a hundred years ago by that English medical genius, Thomas Young, whose book on consumptive diseases, published in 1815, set Krause on the track of the original statement of Hippocrates Young himself, however, seems not to have considered the idea one of much practical importance, for he says that "however extraordinary the practice appears, it is not impossible that it might be beneficial where the adhesion was not such as to prevent the collapse of the lungs, allowing the wounded parts to reunite more readily than in the natural process of respiration, since they would be more intimately in contact with each other, though not more at rest" By the last phrase of this statement Young indicates that he did not grasp the real underlying principle of the effect of pneumothorax The words of Hippocrates fail to indicate whether or not the ancient physicians had any understanding as to why pneumothorax was beneficial, but apparently they did recognize it as a useful procedure in some conditions

THE FATE OF UNCOOKED STARCHES IN THE ALIMENTARY TRACT

Much of the food fuel of man consists of starch, the chief component of the cereals In its natural state the carbohydrate starch occurs in the form of "grains"—unique microscopic packages including more or less cellulose-like material The presence of the indigestible cellulose is commonly charged with interfering with the ready digestion of the starch itself by the alimentary secretions possessing amylolytic enzymes Hence current teaching has supplemented far-reaching empiric experience in dictating such manipulation of starchy foods prior to their being eaten as will decrease the interference of the adherent constituents with ready digestion of the starch Comminution and cooking are the customary processes employed The harder and tougher foods, such as wheat, corn and oats, are first ground fine or milled, while others, such as roots and tubers, are heated with water to "rupture" the starch grains Suitably cooked starchy foods are among the most readily digested components of the human dietary It came as a surprise to physiologists, however, to learn a few months ago from government laboratories[1] that raw wheat-starch and corn-starch, eaten in quantity by man, can be completely assimilated without any physiologic disturbance and without the detection of unutilized starch grains in the feces An extension of these studies of Langworthy and Deuel[2] in the U S Department of Agriculture has now further demonstrated on healthy men that certain raw starches, including corn, wheat, cassava, rice and taro root, were completely digested when eaten in amounts sometimes as large as 250 gm a day Raw tree-fern and true arrowroot (*Maranta arundinacea*) starches were nearly completely digested, but some starch was present in the feces Raw commercial arrowroot (*Canna floridana*) and potato starches showed considerably less complete digestion, large quantities being present in the feces Raw canna starch was even less digestible, its coefficient being only about 50 per cent In these experiments there seems to be a direct relationship between the size of the starch granule and its digestibility Whether or not this relationship is accidental has not been determined One

1 Langworthy C F and Deuel H J Jr Digestibility of Raw Corn Potato and Wheat Starches J Biol Chem 42 27 (May) 1920

2 Langworthy, C F and Deuel H J Jr Digestibility of Raw Rice Arrowroot Canna Cassava Taro Tree Fern and Potato Starches J Biol Chem 52 251 (May) 1922

might readily suppose, the government investigators add, that the larger starch granule contained a thicker cellulose covering, and consequently one more impervious to the digestive ferments than the smaller granule The factor of surface area might also come into consideration, since, the larger the granule, the proportionately smaller surface area for being attacked Clinical experience bears out the relatively poor digestion of uncooked or poorly cooked potatoes The experimental findings regarding the utilization of raw starch from the alimentary tract of man need not be construed as advice to avoid cooking, but rather should be interpreted as evidence of one of the many factors of safety possessed by the human organism

BASAL METABOLISM IN DISEASE

The expressions "basal metabolism" and "metabolic rate' have come into considerable prominence in medicine within the last few years, during which clinical calorimetry has risen to a position of undeniable dignity The symposium on the subject that was reported in THE JOURNAL about a year ago indicated not only the importance of the newer knowledge in this field but also the limitations of its exploitation, the difficulties of technic, and the dangers of improper experimentation Many factors may alter the metabolism of man Food and muscular activity are, perhaps, foremost in increasing the exchange of materials and the output of heat, but the basal metabolism refers to the behavior of the organism in its energy transformation without food and at rest Fever increases the basal metabolism, the rise in temperature being accompanied by an increased heat production corresponding in amount to the degree of fever[1] Such cases are usually attended with a so-called toxic destruction of protein in the body Diseases such as arthritis, though generally regarded as infectious in origin, are believed by some clinicians to be due to disturbed metabolism Observations by Cecil, Barr and Du Bois[2] in cases of arthritis deformans give no support to the latter view The metabolic rate has been found to be normal, and, if arthritis is infectious in origin, the infection cannot be accompanied by increase in basal metabolism or by toxic destruction of body protein The classic instance of the helpful demonstrations of variations in basal metabolism concern disturbances in thyroid function, the high and low rates in hyperthyroidism and hypothyroidism, respectively, being well appreciated[3] With respect to the other glands of internal secretion, however, it must still be said that the variations in basal metabolic rate for which they are responsible cannot yet be foretold It is important at this time to realize and transmit this conclusion, which is clearly indicated in a recent review of the subject by Aub and Taylor[4] The pertinent literature is enormous, but for those who are not sufficiently expert to sift fact from fiction and truth from pseudoscience, the best rule is to maintain an attitude of intelligent skepticism when small variations of basal metabolism are heralded as indicative of large clinical values

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC)

ALABAMA

Hospital Closed—The Red Mountain Sanatorium, Birmingham, established by the Antituberculosis Association of Jefferson County twelve years ago, was closed in July The work will be partly carried on by county appropriation, while the association directs its activities to instruction and preventive work among schoolchildren The sanatorium has cost the association about $18,000 a year, and it is expected that a suitable structure will be erected at the county farm for tuberculosis patients, for which the county would have to appropriate no more than it has already for the antituberculosis association

CALIFORNIA

New Associate Secretary—Following out the policies endorsed by the Council of the Medical Society of the State of California the publicity bureau has appointed Dr Howard H Johnson full-time associate secretary of the state society

Hospital Convention—The second annual convention of the hospitals of California will be held under the auspices of the League for the Conservation of Public Health September 5-8 in Pasadena The council of the state medical society will hold two meetings September 9, the council will meet with the presidents and secretaries of all the county medical societies Dr Charles Lockwood 295 Markham Place, Pasadena, is chairman of the committee of arrangements

Fake Healer Found Guilty—It is reported that "Dr" W H Jones was found guilty on a charge of practicing medicine without a license in Oakland, July 7 He was placed on probation for six months with the provision that he pay $110 to Mrs Burbank, the plaintiff Johns guaranteed to cure an injured knee for $200, of which $100 had been paid by Mrs Burbank He also discovered that her little boy was the victim of some disease which he agreed to cure for $100 Ten dollars was paid him on account

CANAL ZONE

The Gorgas Memorial—Dr R P Strong, who has just returned from his fourth trip to Panama, has announced that it has been decided to establish first divisions of bacteriology, pathology protozoology, helminthology biochemistry, entomology plant pathology and animal diseases, in the new Gorgas Memorial Institute of Tropical and Preventive Medicine, at Panama These departments will be organized with laboratories for research work, particularly in connection with the study of the mode of spread of the most important infectious diseases of man and animals. There will be close cooperation between the institute and the Ancon Hospital and Leprosarium In addition to the foregoing subjects, tropical botany and the biologic effect of sunlight will also receive attention Provision will be made for the instruction of a limited number of students, the courses of instruction to be designed especially for those who have had laboratory training before A limited number of research workers will also be received Dr Strong states that since the president of a small South American republic, already overtaxed, had donated a memorial to an American it was the duty of all American citizens, not only American physicians to provide a suitable endowment fund with which to carry on the work of the institute

COLORADO

Personal—Dr Richard W Corwin has returned to Pueblo after completing a tour around the world, which he undertook in September, 1921 Dr Corwin's trip embraced Italy, Egypt, India China, Japan Korea, Australia and Honolulu ——Dr Philip Work, neurologist at the Woodcroft Hospital, Pueblo, has resigned from that position and will limit his practice to nervous and mental diseases

New Medical Society—The organization meeting of the Arkansas Valley Medical Society was held in La Junta, July 11 The following officers were elected for the ensuing year president, Dr Ralph Johnson La Junta, vice president, Dr M Holmes Cannon City, and secretary treasurer, Dr Harold T Low, Pueblo The association will hold a week end meeting about September 1, in the mountains

DISTRICT OF COLUMBIA

Medical Faculty of Georgetown University—Changes in the medical faculty of the Georgetown University, Washington, have been announced by President John B Creedon Major Joseph P Madigan, who has resigned from the Army is to take the chair of anatomy Dr Thomas E Neill and Dr Murray Russell have been appointed associate clinical professors of surgery and Dr Harry A Ong has been named as associate clinical professor of medicine

FLORIDA

State Medical Meeting—At the forty ninth annual meeting of the Florida Medical Association held in Havana, Cuba, June 27-28, under the presidency of Dr S R M Kennedy, Pensacola, the following officers were elected for the ensuing year president, Dr Leonidas M Anderson Lake City, vice presidents, Drs Herman Marshall Taylor, Jacksonville, Joseph L Kirby-Smith, Jacksonville, and Leland F Carleton, Tampa, and secretary, Dr Graham E Henson, Jacksonville

Health Conference—A conference was held in Orlando, July 5 6, of state, health and sanitary authorities for the purpose of standardizing and rendering uniform state laws governing health and sanitation throughout the state Dr Raymond C Turck, Jacksonville, state health officer, Dr Jesse R Harris, Tampa, head of the department of health, Dr Arms Jacksonville, city physician, W E A Wyman, St Petersburg, pure food inspector, and Dr Alvin J Wood, city physician of St Petersburg, were among the many that attended the conference

GEORGIA

Prison Sentence for Physician—It is reported that Judge Grubb recently sentenced Dr H E Pontius, Atlanta, to eighteen months in the federal penitentiary at Atlanta, for violation of the Harrison Narcotic Law

ILLINOIS

Personal—Prof William C Rose, Ph D who has held the chair of biochemistry in the University of Texas Department of Medicine, Galveston since 1913 has resigned to become head of the department of chemistry of the University of Illinois, Urbana

Illegal Practitioner Fined—It is reported that Theodore Dilinsky, aged 71 of Houston Avenue South Chicago, was fined $50 and costs by Judge Joseph W Schulman recently, for practicing medicine without a license Dilinsky attended a 3 year old child who had been overcome by gas The child died

Physicians Fined—It is reported that Drs William R Wesenberg and J F Hargan, both of Mound City recently paid $10 each and costs for failure to report births The complaints against the physicians were filed by the local state s attorney at the request of a special agent from the state department of public health

New Bulletin on Medical Service in Schools—The state department of public health announces the completion of a new bulletin setting forth detailed instructions in reference to the medical inspection of schoolchildren The function of the school physician, the place and work of the school nurse and the part that should be played by the teacher, as viewed by the department, are all described It is felt that the bulletin will be especially helpful to public health officers, school nurses and teachers Copies may be had after August 15 by persons or organizations in Illinois without cost

Pasteurization Campaigns—The state department of public health has recently put in motion a campaign in favor of milk pasteurization A model ordinance has been drawn up and the twenty odd district health superintendents have been instructed to take advantage of every opportunity and to use every effort at their disposal in securing the adoption of the ordinance by the various communities in their several districts Two recent and rather serious outbreaks of typhoid fever which were traced to the use of raw milk have added impetus to the campaign in certain sections Nearly a score of the larger cities have the proposition of adopting the ordinance now up for consideration, while half a dozen have already adopted and are now enforcing it

Hospital News—The Sisters of St Francis of Peoria have recently purchased the Holmes Hospital, Macomb, for $65,000 The institution will be consolidated with the present St Francis Hospital——The contract has been awarded for an addition to St John's Hospital, Springfield, at a cost of $15 000——Bids will be taken to August 15, on the $300,000 tuberculosis hospital building to be erected at Edwardsville by the county commissioners——The new $75,000 addition to St Francis Hospital Litchfield, has just been completed, and another building will be erected for a power plant and employees quarters at a cost of $35,000——The John Marshall Browning Hospital, recently completed at DuQuoin was dedicated July 20 Dr Clarence W East, chief of the division of child hygiene and public health nursing of the state department of public health, delivered the principal address

Chicago

Personal—Dr William A Evans, medical editor of the Chicago *Tribune* delivered an address before the Canadian and Ontario dental associations at the University of Toronto, Canada recently——The king of Denmark has conferred a knighthood on Dr Peter Clemensen, Chicago, former member of the board of education

Czechoslovak Hospital—At a recent meeting of American citizens of Czechoslovak descent in Chicago, plans were made for the erection of a Czechoslovak Hospital For this purpose $30 000 has already been subscribed and a considerably larger sum pledged The purpose of this institution is to provide physicians and nurses who speak their own language for the Czechoslovakians resident in and around Chicago

INDIANA

Health Board Secretary Resigns—Dr John N Hurty, Indianapolis, for more than twenty six years secretary of the state board of health, presented his resignation, July 19, to take effect September 30 Dr Hurty is Republican nominee in Marion County for the legislature His successor has not yet been named

IOWA

Personal—Dr Marcus P Neal, assistant professor of pathology and bacteriology at the State University of Iowa College of Medicine Iowa City, has accepted a position as professor of pathology and bacteriology at the University of Missouri School of Medicine, Columbia——Dr Edgar M Medlar head of the department of pathology at the University of Iowa, has left for Mount McGregor, N Y, where he will do research work——Dr John Shuman, Sioux City, has accepted a position as professor of internal medicine at the American University, Beirut, Assyria, to succeed Dr Harry Graham recently deceased Dr Shuman will leave for his post abroad about the end of August——Dr John H Stalford, Sac City was recently reelected president of the Wall Lake District Medical Society

KENTUCKY

Summer School—A health conference, with the slogan Live a little longer' was the feature of the summer school sessions at the University of Kentucky, Lexington July 10-15 Dr Percy K Holmes, head of the department of hygiene and public health of the university, presided Among the speakers were Dr Edith Hale Swift of the American Hygiene Association, New York, Dr Annie Welch, director of the Bureau of Child Hygiene Louisville, and Dr John McMullen, U S Public Health Service

LOUISIANA

Public Health News—It has been officially announced by the U S Public Health Service that plague eradication work will be discontinued in New Orleans For nearly a year not one single trace of rat infection has been discovered by the federal health workers under the direction of Dr Marion S

Lombard, and New Orleans has been given a clean bill of health as far as plague is concerned

Campaign Against Ants—The New Orleans Board of Health has given official approval to an extensive campaign against ants in the city, following individual requests from hundreds of residents Surveys of the result of the campaign against the ant last year show that the extermination work was 95 per cent effective The cost of ridding the entire city of ants would be approximately $40,000, making an average of $12 for each block The U S government entomologist will have charge of the campaign Organization must be perfected and the funds which make extermination work possible must be in hand by August 15

Hospital News—The Eye, Ear, Nose and Throat Hospital, New Orleans, will move into a new building at Tulane Avenue When the new four-story fireproof building is completed, the accommodations will represent an outlay of $500,000 Bequests and gifts from various people have made this possible $100 000 being donated by Isaac Delgado, $20,000 by A C Hutchinson, $6,000 by Thomy Lafon, the negro philanthropist, and $50,000 by Mrs John Dibert Dr Henry Dickson Burns is surgeon-in-chief He succeeded the late Dr DeRoaldes, founder of the institution——A site has recently been purchased in New Orleans by Mrs Thomas of New York for a home for worthy old people and convalescent mothers This institution will be known as the Holmes-Thomas Home and Mrs Thomas has set aside a trust fund of about $800 000 for the erection and endowment of the home The donor requests that not more than one third of the principal be expended for the construction of the institution Dr Rudolph Matas and Dr A B Dinwiddie, president of Tulane University, have been requested to act on the board of directors of the home fund corporation——A twin building joined by another structure to the first quarters of the St Rita Surgical Infirmary, New Orleans is being erected to double the capacity of the institution Two operating rooms, more than fifty beds and many other improvements will ultimately be incorporated in the hospital

MARYLAND

Personal—Dr George W Corner, associate professor of anatomy at Johns Hopkins University Medical School, Baltimore has been appointed head of the department of anatomy in the new school of medicine and dentistry now being organized at the University of Rochester, N Y

Hospital News—Work has been started on the $200 000 hospital building and kitchen of the Maryland State Sanatorium Henrytown——Working drawings for the municipal hospital for infectious diseases to be erected at Montebello, Baltimore have been signed by Dr C Hampson Jones, commissioner of health Baltimore

Test of Birth Records in Maryland—Birth registration of children born in Maryland is to be subjected to a complete test under a plan worked out by Dr John S Fulton, secretary of the state department of health, in cooperation with the Maryland League of Women Voters Under the plan, 1 000 mothers, members of the league, will request from the state department of health certificates of the registration of the births of their children under 5 years of age There is a law in the state requiring a report to the state department of health of the birth of every child but it is believed the figures are far from being complete All of the work is being done to prepare for the opening of the child hygiene bureau, of which Dr J H Mason Knox has been recently appointed chief When it is ascertained where the health department stands in this matter, steps will be taken to put the bureau in shape to compute the death rate of children in Maryland and to take immediate steps to lower it

MASSACHUSETTS

Floating Hospital—The Boston Floating Hospital started from the North Pier, June 28 on its twenty-ninth annual health voyage for children The ship leaves daily, returning in the evening, and anchors for the night It has accommodations for about 115 permanent patients, and from eighty to 100 day patients The staff is composed of seventy nurses and sixteen physicians, under the direction of Dr Henry I Bowditch

Public Health Lectures—The Committee on Public Health of the Massachusetts Medical Society has been able, during the last three years, to arrange with well known specialists to give talks at meetings of the district medical societies in Massachusetts A similar arrangement has been made this year and the following physicians will speak without charge before the societies, for thirty or forty minutes, on subjects relating to the promotion of public health Drs Jose Penteado Bill, Frank C Dunbar, Walter E Fernald, Timothy Leary, Edwin H Place, C Morton Smith, George Gilbert Smith, Lesley H Spooner, William C Woodward and Thomas F Kenney George H Wright D M D, lecturer on hygiene at Harvard Dental School, will give lectures on dental surgery

MICHIGAN

Hospital News—A new hospital will be constructed at Traverse City to take the place of the old General Hospital, as authorized by the state administrative board Construction work will be started this month on the new modern building The institution will have a capacity of fifty beds and well equipped maternity surgical and medical wards It will be under the direction of Dr J D Munson who is now superintendent of the Traverse City State Hospital——The Westerlin Hospital Iron Mountain, has been purchased by the Franciscan Sisters of Charity, it was recently announced——The new St Lawrence Hospital Lansing will be erected in the near future at a cost of $350,000 The Sisters of Mercy will donate $150 000 toward the building

MONTANA

State Medical Meeting—At the annual meeting of the Medical Association of Montana, held at Great Falls, July 12 13 under the presidency of Dr W W Andrus, Miles City, the following officers were elected for the ensuing year president Dr Harmon T Rhoads Choteau, vice presidents, Drs P A Dolan Helena, James B Reynolds Great Falls, and Lawrence R Packard Whitehall, and secretary-treasurer, Elmer G Balsam Billings (reelected)

Personal—Dr Howard L Botts Billings, county health officer has resigned to accept a position in Seattle Dr Eri M Farr has been appointed successor to Dr Botts——Dr Ernest D Hitchcock epidemiologist for the state board of health and director of the hygiene laboratory, Helena, has resigned to associate himself with a clinical group in Great Falls Dr Hitchcock will take over the diagnostic work of the clinic and for the Deaconess Hospital

NEBRASKA

Personal—Dr Margaret W Koenig, Lincoln, child welfare worker for the Lincoln board of education, has left for Washington D C, to take up rural child hygiene for the government under the provisions of the Sheppard-Towner bill Her first work will be in Tennessee

Health Officer Urges Reports on Contagious Diseases—Dr I H Dillon chief of the bureau of health of Nebraska, has recently called the attention of physicians of the state to their laxity in reporting contagious diseases Evidence is cited to indicate that in some instances more deaths than cases are reported making it impossible to secure adequate statistics In concluding his statement, Dr Dillon states that he is opposed to "state medicine' but he warns "Unless the medical profession, both individually and collectively, are able to show a better record the public will, in the near future, provide for some form of state medicine by legislative enactment, for its own protection"

Nutrition Institute—At the summer school of education conducted by the Cleveland Public Schools a nutrition institute was held recently at Lincoln The Lincoln Institute was the first to be held by the department of medical inspection in the city About 100 people were in attendance, including a number of physicians Dr Katharine H R Wolfe organized this department Dr William R P Emerson gave addresses at dinners and conferences of representatives of the leading child-helping organizations including the Associated Charities and juvenile court the educational executives of the University of Nebraska and of the public schools and members of the medical and dental associations In September, an institute will be held in Hartford, under the direction of the nutrition clinics for delicate children, followed by others in Poughkeepsie, Battle Creek, Denver and Honolulu

NEW JERSEY

Psychologic Test at University—It has been recently announced that Princeton University will require every man entering the college to undergo a psychologic test in addition

to the regular examination A trial period of two years has been set for the test If however a man fails to pass the test, but his written examinations are satisfactory, he will not be disqualified At the end of the trial period if the report of the faculty committee which has charge of the test proves satisfactory the psychologic test will be thereafter essential as a written examination

NEW YORK

Columbia University Teaches Eye Conservation—The first training course in eye conservation ever given for teachers under the auspices of an American university was opened recently at Columbia University, with a class of twenty one A feature of the course is an observation class composed of children from New York City schools whose defects of vision have placed them in the sight saving classes Dr Robert R Irwin, supervisor of the sight-saving department of the public school of Cleveland is general director of the Columbia course A committee composed of representatives of city, state and national organizations which is cooperating with Columbia in the arrangement of these courses is headed by Dr Thomas J Riley

Hospital News—A new Jewish Hospital will be erected at Buffalo at a cost of $1 000 000——The cornerstone of the St Francis Hospital, Poughkeepsie was laid July 4——A three story addition will be erected at the Buffalo General Hospital——Construction work will soon be started on the new buildings for Moses Hospital Ticonderoga to be erected at a cost of $250 000——Eleven tuberculosis hospitals in the state have adopted occupational therapy as part of their regular treatment——A new addition will be made to the state laboratories at Albany at a cost of $90 000——The Unity Hospital Brooklyn has acquired ground for the purpose of erecting a modern institution devoted to the treatment of diseases of the eye, ear nose and throat and oral surgery The building will be four stories high and will be equipped with modern facilities——The Methodist Hospital Brooklyn will inaugurate a campaign for $1 000 000 to erect a new maternity pavilion——Construction work has been started on the new hospital to be erected on the grounds of the state Odd Fellows Home at Lockport at a cost of approximately $40 000——The Bronx Maternity Hospital will build a five story annex to be used as a private pavilion This building will contain about fifty beds and will enable the hospital which was opened two years ago to use its present quarters exclusively for charitable work——A public health laboratory has been established in the Champlain Valley Hospital at Plattsburg, for Clinton County by the action of the board of supervisors in appropriating $2 000 annually toward the maintenance of the laboratory This laboratory was established through a gift from David Merke of Plattsburgh in memory of his parents and is known as the Merke Memorial Laboratory

New York City

Find Lost Radium Under Ton of Ashes—A tube of radium valued at $1,000 was lost at the Methodist Episcopal Hospital, July 12 After a vain search the radium was located by means of the electroscope beneath about a ton of ashes that had passed through an incinerating plant in the hospital yard The radium, a 10 milligram tube was uninjured by its passage through the furnace

Associated Outpatient Clinics—At a meeting of the section of ophthalmology, the many problems represented by outpatient work in eye clinics was brought to the attention of the society Consideration was given to topics such as lack of professional standards paucity of equipment, overcrowding in all clinics, especially for work on refraction, the abuse of the clinic by patients able to pay, failure of patients to secure glasses when prescribed unsatisfactory financial arrangements with opticians lack of uniformity of fees charges for admission drugs laboratory examinations and glasses, lack of organization for research incompleteness of records and inadequacy of filing systems A committee was appointed for studying these topics with Dr Walter E Lambert as chairman Dr Conrad Berens Jr, made a study of professional methods equipment, records, teaching and research in nine institutions Studies of the admission procedure fee systems and the provision of glasses in four special eye clinics and eight eye clinics in general dispensaries were made by Dr Gertrude E Sturges In order to ascertain the need for systematic follow-up system in eye clinics, a study was made of 5 200 records from five representative clinics A summary of the findings of the studies, together with the conclusions and recommendations arrived at by the committee will be presented in the report of the section which will be available in the fall

NORTH CAROLINA

Free Vaccine Dispensaries—Free dispensaries for typhoid and diphtheria vaccine will be conducted in Wake County in July and August under the direction of Dr R T Long Dr Long is substituting for Dr Bulla, who is very ill

Medical Meeting—At the Sixth Councilor District Medical Society of North Carolina held in Durham recently Dr Harris H Bass Henderson was elected president and Dr Eric A Abernethy Chapel Hill vice president Dr Burton W Truett Durham, was reelected secretary treasurer

OHIO

Personal—Dr Harry S Noble St Marys has been elected president of the Auglaise County Medical Society——Dr James H Smith Holgate has been appointed county health officer of Henry County and will reside at Napoleon——Dr Arthur O Peters health commissioner of Dayton has been elected president of the Montgomery County Medical Society to succeed Dr C N Chrisman

Public Health News—The standard of health officers has been raised considerably since the change from a health officer for each township village and city to a health commissioner for each city and one for each county Under the old plan there were 2 150 health officers in the state They were elected by health boards and in the smaller places it was difficult to obtain men who were qualified for the work many of them having no knowledge of medicine or health work Of the 171 health commissioners who have replaced them all but twelve are physicians, and two of the twelve are public health nurses A correspondence school course provides them with a thorough knowledge of the work required further augmented by a series of lectures by Dr F Shaffer who has been placed in charge of the lecture bureau

OREGON

Amalgamation of Medical Societies—Preliminary plans have been made for the ultimate amalgamation of activities of the Portland City and County Medical Society the Portland Academy of Medicine and the Oregon State Medical Association Representatives of each organization were summoned by Dr John Guy Strohm, president of the city and county medical society July 4 City Health Officer George Parrish was appointed chairman of a committee of five to investigate the situation with Dr Alpha E Rockey, Dr William B Holden Dr Clarence J McCusker and State Health Officer Frederick D Stricker The three organizations now have an annual overhead of approximately $21 000 It is estimated that by combining the expense will be materially reduced and funds saved for the construction of a central building as headquarters for the combined societies

PENNSYLVANIA

Personal—Dr Richard J Behan Pittsburgh, gave an address on Pain at a recent meeting of the Allegheny Garrett County Medical Society at Grantsville——Dr James G Cumming Oil City has been appointed chief of the bureau of health by Health Director Furbush——Dr Lawrence Webster Fox Philadelphia recently sailed for Scotland where he will read a paper before the annual convention of the British Medical Association at Glasgow——Dr Pascal Brooke Bland Philadelphia was the principal speaker at a meeting of the Cumberland County Medical Society at Vineland July 11——Dr Harry B Schaeffer Shillington has been appointed prison physician at Reading to succeed Dr Henry P Brunner who resigned recently——The degree of doctor of laws has been conferred by Lafayette College on Dr Alfred Stengel professor of medicine in the University of Pennsylvania——Dr F T Aschmann Pittsburgh chemist to the Pennsylvania Bureau of Foods has been elected chairman of the board of chemists of the bureau to succeed the late Prof William Frear

Philadelphia

Ayer Clinical Laboratory—The bulletin of the Ayer Clinical Laboratory of Pennsylvania Hospital which has been suspended for eleven years, is again being published It is expected the series now under way will be permanent

SOUTH CAROLINA

Health Officers' Meeting—The annual meeting of the South Carolina Association of County Health Officials was held in Charleston, July 3-5. Dr. Luther A. Riser, Columbia, director of rural sanitation of the state board of health, and Dr. Leon Banov, health officer of Charleston County, were reelected as president and secretary, respectively.

Venereal Disease Clinics—The directors of the venereal disease clinics in Spartanburg, Orangeburg, Greenville and Columbia held a meeting in Columbia, June 27, with Dr. James A. Hayne, state health officer, who represents the government in venereal disease work. The officers of these clinics discussed an educational campaign featuring the need of venereal disease clinics in each county in the state. The federal government has appropriated $3,583 for the venereal disease clinics in the state on condition that the clinics appropriate a like amount. The four clinics mentioned have met this condition, so that the clinics have $7,166 to carry on the work, with various contributions and subscriptions from other sources.

VIRGINIA

Mental Health Commission—The governor has appointed Dr. S. C. Hatcher, Ashland, chairman of the commission on mental health, which was created by an act of the last General Assembly. Dr. Thomas S. Heming, Jefferson, Dr. William D. Prince, Stony Creek, Dr. William F. Drewry, Petersburg, Dr. Albert S. Priddy, Colony, Dr. Ennion G. Williams, Richmond, and Dr. Paul V. Anderson, Richmond, are other members of the commission.

Personal—Dr. Charles Calhoun Hedges, Marietta, Ga., was appointed instructor in anatomy at the University of Virginia recently.——Dr. Frank Helvestine, Jr., Roanoke, has been appointed instructor in pathology at the University of Virginia, Charlottesville.——Dr. Percy Harris, who was recently appointed city physician for Lynchburg, has resigned the position and decided to remain at Scottsville.——Dr. Edward S. Lester, Witt, has been appointed examining physician by the Norfolk and Western Railway and has moved to Bluefield, W. Va.——Dr. Michael W. Minor, Comorn, has been elected president of the board of directors of the bank of King George.——Dr. Albert C. Lancaster has been elected a member of the city council of Martinsville.——Dr. Stuart McGuire, Richmond, is one of the five men appointed by the governor to complete the personnel of the new war memorial commission, created by terms of a resolution adopted during the last session of the General Assembly.——Dr. William L. Moss, former professor of medicine at the Medical School of Harvard University, Boston, has been appointed head of the school of medicine at the Medical College of Virginia, Richmond.

WEST VIRGINIA

Personal—Dr. Aaron Arkin, professor of pathology and bacteriology at the West Virginia School of Medicine, Morgantown, has been granted a year's leave of absence for study and research abroad. He will spend the year in Vienna, Berlin, Paris and London doing work in pathology and medicine.

CANADA

Canadian Public Health Association—The annual meeting of the association was held in St. John, N. B., June 6-7, under the presidency of Hon. W. R. Roberts, minister of health of New Brunswick. The following officers were elected for the ensuing year: president, Dr. William C. Laidlaw, Edmonton, Alta.; vice president, Dr. Joseph A. Baudouin, Montreal; secretary, Dr. John T. Phair, Toronto, and treasurer, Dr. Albert G. Fleming, Toronto.

Honor for Physician—On the occasion of his retirement from the University of Toronto Faculty of Medicine, a dinner was given in honor of Prof. Irving H. Cameron, June 2, and a portrait of him was presented to the University by Prof. Clarence L. Starr, chairman of the subscribers committee. More than 100 of the subscribers to the portrait attended the banquet. The university was represented by the chancellor, the president and Sir Joseph Flavelle, of the board of governors, who joined in expressing their pleasure in accepting for the university so fitting and lasting a memorial.

Medical Council of Canada—At the annual meeting of the council held in Ottawa, June 1, the following officers were elected: president, Dr. Louis P. Normand, Three Rivers, Que.; vice president, Dr. James M. MacCallum, Toronto, and registrar, Dr. Robert H. W. Powell, Ottawa. Dr. A. G. Brett, Edmonton, presided. There are thirty-two members of the council, which is an administrative body created under the Canada Medical Act, consisting of representatives from the provinces and the universities. Licentiate of the Medical Council of Canada (L. M. C. C.) is the qualification created by the Canada Medical Act and it is accepted in all provinces as sufficient for license. It was decided to offer an examination in English and French, at Montreal, Que., and Halifax, N. S., October 10.

Medical Association News—The Canadian Society of Pediatrics was organized at a meeting in Toronto, recently. Dr. Alexander D. Blackader, Montreal, was elected the first president of the society. Dr. Alan G. Brown, Toronto, and Dr. Morgan, Toronto, were elected vice president, and secretary-treasurer, respectively. Drs. Henry P. Wright, Montreal, Alan W. Canfield, Toronto, and John G. A. Campbell, Ottawa, are the members of the executive committee.——The annual meeting of the British Columbia Medical Association will be held, August 21-26. The place of meeting has not yet been announced.——The Canadian Radiological Society applied at the recent meeting of the Canadian Medical Association in Winnipeg to be recognized as a separate department of medicine in affiliation with the Dominion organization. Its active membership consists exclusively of reputable medical men, members of the Dominion Association, who are actively engaged in this specialty and derive the major portion of their income from it. They have recently established a bureau of consultation and are prepared to give advice to members of the profession on all matters pertaining to the use of roentgen ray and radium and also to assist and advise institutions and physicians who desire to purchase apparatus in the selection of their equipment.

PHILIPPINE ISLANDS

Child Welfare Clinic—The Clinica Infantile has been established in the city of Iloilo for the treatment of babies, children, pregnant women and mothers desiring medical advice and treatment, by the Perfection Lodge, Lopez Jaena, No. 3 with the help of some lodges of higher degree. This clinic is operated by physicians who receive no salary for their services and is open for consultations and treatments for two hours daily, free of charge. There is also no charge for medicines. The present clinic is temporarily in the Gonzalez Building but a new structure is being erected at a cost of, approximately, 3,000 pesos which will be known as the Clinica Infantile Masonica, with three emergency beds. Additions will be made to the building yearly, with the object of using it eventually for a charity hospital. A campaign has already been inaugurated to raise funds for this purpose. Another clinic for the treatment of tuberculosis will be established in connection with the Clinica Infantile when enough money is available. All the attending physicians are Masons in good standing, but special credit is due to Drs. Zaldariaga Gilchrist and Hinojales and Mr. E. Gonzalez for their untiring efforts to make the clinic a success. A baby contest was held in June, in which more than fifty babies took part. Ten prizes were distributed to the mothers of the winning babies.

GENERAL

Warning!—An Old Trick Revived—A Chicago physician writes that a young man called at his office representing himself to be the son of a down state physician and telling a tale of financial distress because of his having been robbed, etc. He requested a sum of money sufficient to take him to his own home and promised to return the loan by the next day. When the applicant secures the loan, the transaction is finished.

Pacific Coast Association of Anesthetists—At the annual meeting of the association at Yosemite Valley, the following officers were elected for the ensuing year: president, Dr. George P. Waller, Los Angeles; vice president, Dr. Mary E. Botsford, San Francisco, and secretary-treasurer, Dr. Eleanor C. Seymour, Los Angeles. The next meeting of the association will be held in San Francisco, June 25-27, 1923, in joint session with the American Association of Anesthetists and in conjunction with the Annual Session of the American Medical Association.

National Health Conference—"Making America healthier" was the object of the Conference of Health Education and the Preparation of Teachers at Lake Mohonk, N. Y., June 26-July 1. The Child Health Organization of America and the U. S. Bureau of Education is cooperating to teach teach-

ers how to convey to children in easily understandable terms the idea of health habits Charles E A Winslow, M S M A of Yale University School of Medicine, was chairman of the program committee and Dr Thomas D Wood of the Teachers' College Columbia University, was chairman of the sessions for the week Drs John R Finley, state commissioner of education Mary Swartz Rose Albert Aheils, Willard S Small of the U S Bureau of Education, Ray L Wilbur and William D Wirt were other members of the committee Dr L Emmett Holt, president of the board of trustees of the Child Health Organization of America, delivered the address of welcome

LATIN AMERICA

Personal Tribute to Cuban Physician—Spanish public health officials tendered a banquet to Dr C E Kohly, the Cuban delegate to the Sanitary Organization Congress to be held in Madrid Many of the most prominent Spanish physicians attended, and a speech was delivered by the Spanish secretary of education

Second Mexican Infant Welfare Congress—A call has already been issued for the Second Infant Welfare Congress, which will be held in Mexico Jan 2-9, 1923 The secretary-general is Dr F Castillo Najera The chairman of the several sections are eugenics Prof I Ochoterena, hygiene Dr R Carrillo medical pediatrics, Dr J Cosio, surgical pediatrics Dr Diaz Lombardo, education, Dr A Pruneda, propaganda Luis Jaso

New Argentine Monthly—A new illustrated medical magazine, *Album Medico Argentino* has begun publication in Argentine It will make a feature of illustrations, and all papers published will be accompanied by the author's photograph and autograph Aside from its scientific section there will be departments of social literary and artistic medicine The first article by Dr Elisco Canton traces the establishment of the protophysician's office in 1778 which anteceded the foundation of the Argentine medical school in 1801 Before that time, medical matters were under the control of the Lima medical office The subscription to the *Album* is 12 pesos ($4 38) The editors insist that theirs is not an advertising scheme although at first sight it may seem so It is printed on good paper, large magazine size, and contains an average of twenty pages The address is Venezuela 766, Buenos Aires

Mexican Medical Congress—Arrangements are being made for the celebration of the Seventh Mexican Medical Congress which will be held at Saltillo, Sept 3-10 1922 The following organizing committee is in charge president, Dr D M Velez, first vice president, Dr J M Rodriguez, second vice president, Dr J Valdez Sanchez secretary-general, Dr E Landa, treasurer, Dr G M Malda, reporter, Dr T G Perrin, members Drs F Bulman R Silva, F Castillo Najera, Mr A Aragon and Dr E F Montaño An appropriation has been asked of the national government One of the novelties of the congress will be the sending by the National University of a group of students who will represent the six different medical years The organizing committee has begun the publication of a special bulletin to discuss matters related to the congress Previous congresses were held in 1892, at Mexico City in 1894 at San Luis Potosi, in 1897, at Guadalajara, in 1910, at Mexico City, in 1918 at Puebla, and in 1920, at Toluca One of the plans is to have each of the Mexican states appoint a physician to study some local disease and report the results at the meeting

FOREIGN

Gift to Paris Academy—One million francs has been bequeathed to the Paris Academy of Medicine by the will of the late Prince Albert of Monaco

Special Degree in Patologic Anatomy—The *Liege Medical* of July 9 is devoted entirely to the inaugural thesis of Dr Jean Firket, when the degree of *Docteur special en Sciences anatomo-pathologiques* was conferred on him by the medical faculty of the University of Liege His subject was "Regeneration of the Blood Platelets After Saponin Poisoning and After Defibrination of the Blood" It was followed by a historical sketch of experimental cancer research to date

New Heart Journal in Spain—A journal entitled *Archivos de las Enfermedades del Corazon y de los Vasos* has begun publication in Spain It will appear irregularly, whenever sufficient material accumulates It is printed on good paper, with many illustrations The editor is Dr Duran Arrom Paseo de Gracia, 99, Barcelona, who is apparently also the author of all the papers appearing in the first number The price is 7 pesetas ($1 09)

Union Medical School—Mission and educational bodies of East China have set in motion a project to build in Shanghai a union medical school at a cost of $500 000 thus reviving an undertaking originally planned by the Rockefeller Foundation but later abandoned St John's University of Shanghai is one of the institutions actively supporting the project This school has had a medical department for more than a quarter of a century When the Peking Union Medical College was being erected by the Rockefeller Foundation a plan to expand St John's Medical School into a Union College at Shanghai was proposed to the Foundation and approved but the purpose was abandoned in 1920 and has only been revived again recently

Annual Meeting of the Netherlands Medical Association—The seventy-third annual meeting of the Nederlandsch Maatschappij tot Bevordering der Geneeskunst was held July 3 at Maastricht in the extreme south of the country The president Dr H Klinkert opened his address with a quotation from a leading Swiss physician of the last century Dr Sonderegger who wrote on his seventieth birthday

When I get to Heaven, I will devote myself for the first five thousand years to the study of medicine What bliss to study the old problems with supernatural insight and ways and means! Klinkert's brilliant address was devoted to the question whether the increasing tendency to specialism is rendering the family physician superfluous He reviewed his own fifty two years of practice as he sought to carry on the sacred torch placed in his hands by the masters before him C'est une belle vocation mais un rude metier," but he is convinced that the position of family physician will grow more and more in prestige and importance 'The family physician will keep abreast of progress in the specialties

The scientific and ethical level of the medical profession in a country is the gage of its rank in civilization'

Personal—Dr John Hill Abram has been appointed to the chair of medicine of the University of Liverpool England made vacant by the resignation of Prof Thomas R Glynn ——Dr John Thomson and Dr Norman Walker have been equally awarded the Victoria Jubilee Cullen Prize by the Royal College of Physicians Edinburgh for the greatest benefit done to practical medicine ——Sir Thomas Lewis recently returned to England after four weeks sojourn in America ——Lieut-Col B H Deare professor of medicine at the Medical College of Calcutta India, has been appointed surgeon-general with the government of Bengal ——The pupils and other friends of Prof L Bolk of the chair of anatomy at the University of Amsterdam recently presented him with his portrait in oil with a number of complimentary addresses over 570 persons contributed to the fund ——Prof A Moussous of the chair of children's diseases at the University of Bordeaux was presented in June with a souvenir plaque and other tributes on the occasion of his promotion in the Legion of Honor ——The Albrecht von Graefe medal is awarded every ten years by the German Ophthalmologic Society The previous recipients have been Helmholtz, Leber and E Hering and this year it was awarded to Hess of Munich Professor von Hess was the guest of the American Medical Association at the Atlantic City meeting in 1907 ——Professor Grober of Jena has returned from a lecture trip to Argentina ——Dr Valle Aldabalde and Dr Vicente Gimeno were elected to the two vacant seats in the Academia Nacional de Medicina at Madrid ——Dr A Ferrannini editor in chief of the *Riforma Medica*, has been decorated by the king of Italy as commander of the Corona d Italia ——A farewell banquet was tendered to Dr U Carpi at Lugano as he left to take charge of the large public hospital at Milan ——Dr Gomez Ulla of Madrid was recently tendered a banquet by 300 of his clients and other friends ——Dr Victor Manuel Nogueras was presented with an engraved tribute signed by all the soldiers who had passed through his hands in the military hospitals at Melilla during the recent campaigns in northern Africa The occasion was a banquet offered him when on leave in Madrid The government, the army medical department the Spanish Red Cross army nurses and others joined in the tribute The *Medicina Ibera* gives details of the addresses

Deaths in Other Countries

Dr L Benini of Modigliana Italy, succumbed to postoperative pneumonia after an operation for hydatid cyst of the liver aged 63 ——Dr P Gerosa, noted for his campaign to popularize sanatorium treatment for the tuberculous He bequeathed his property to the sanatorium at his home, Intra

——Dr W Richter, chief of the dermatologic service of the Chemnitz public hospital——Dr Ramon Salto of Madrid ——Dr F Kratschmer-Forstburg of Vienna, at one time surgeon-general of the Austrian army, aged 79——Dr Emil Sioli, formerly professor of psychiatry at Frankfort, aged 70

Government Services

Maneuvers at Medical Training Camp

The Medical Department Reserve Officers' Training Corps camp, which has been in operation at Carlisle Barracks, Pa, since June 22, was temporarily removed to the Gettysburg battlefield, July 1, for the maneuvers of the U S Marines Two days previously, an exhibit of experimental models of proposed new field devices, as developed by the Medical Department Equipment Laboratory at Carlisle, was set up in the camp of the Marines at Gettysburg, for the purpose of demonstrating this equipment to the officers of the Marines and the attached naval medical personnel The medical exhibit consisted of an experimental model of a new hospital ward tent for base and evacuation hospitals, together with a proposed new combat wagon, a veterinary loading apparatus, a veterinary ambulance, one standard ambulance spare parts trailer, one wheeled litter carrier, a new food cabinet, and an evacuation hospital electric lighting unit The lighting unit was operated successfully and received much favorable comment The exhibit was in charge of Major John P Fletcher, Medical Corps, U S Army, the director of the Medical Department Equipment Laboratory at Carlisle July 4, there was reenacted the mimic battle of Gettysburg, which was executed with reference to all the practices and inventions with arms of modern production At the conclusion of the maneuvers, tents were struck and the R O T C students returned to their own camp at Carlisle Barracks, to resume their training

Retiring Board for Army

The board of general officers has been appointed to supervise and make recommendations for the reduction of the number of officers in the regular Army, in accordance with a recent act of Congress Major-Gen Joseph T Dickman retired, will act as president Other members of the board include Major-Gen Merritt W Ireland, Surgeon-General of the Army, Major-Gen Henry P McCain (retired), former adjutant-general, and Brig.-Gens Andre W Brewster and Ernest Hinds

Promotions in the Navy

Three officers in the Medical Corps of the Navy have been recommended for promotion by the selective board of the Navy They are Lieut.-Coms Addison B Clifford, Eugene A Vickery and Richard A Warner All are to be advanced to the grade of commander

Reduction of Army Medical Personnel

In an official report issued by the War Department and signed by General Pershing the number of officers in the Medical Department of the Army to be eliminated as a result of the recent appropriation act of Congress was announced It follows

Medical Administrative Corps	143
Dental Corps	76
Veterinary Corps	32
Medical Corps	66
Total	317

The procedure to be followed by the elimination board in selecting the officers to be retired or discharged from the service is also included in the report An epitome of it reads

First All officers having less than ten years service who are eliminated will be discharged and given a year's pay

Second Officers having more than ten years service but less than twenty will be retired on a basis of 2½ per cent of the pay for each year's service thus a Captain or Major with twenty years service will receive 50 per cent of $2 400 or $3 000, as the case may be in form of monthly payments as retired pay

Third Officers serving more than 25 years will be retired if physical disability exists on the regular retirement status that is 75 per cent of the rate of pay at the time of retirement It has been pointed out that few Lieutenants will be affected in the retirement plan as practically none of them has ten years service to his credit

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 3, 1922

The Imperial Bureau of Entomology

Sir Arthur Shipley, in the *Times* recently, contributed an interesting account of the Imperial Bureau of Entomology The bureau arose from the Entomological Research Committee, which was instituted in 1909, and was established in 1913 to encourage and coordinate entomological work throughout the empire in relation to human, animal and plant diseases The committee of the bureau is widely representative, and includes the chief entomologist in each of the dominions Its director is Dr G A K Marshall The extent of the work done is shown by the fact that during the last year some 53,000 insects have been submitted for identification by eighty-two correspondents scattered throughout the empire This collection often contained, of course, more than one specimen of a single species Identifications of 4,300 different species have been issued in the same period Much of the material is returned to the collectors, but 13,000 specimens were presented to the British Museum, of which 171 were types or species new to science, and 428 were species not previously represented in the national collection About 5,000 classified bloodsucking insects were distributed to various institutions throughout the empire for teaching purposes

Apart from collecting, identifying and registering this vast mass of material, the bureau issues two periodicals of great value One, a quarterly, the *Bulletin of Entomological Research* contained in the latest number forty original papers and comprised nearly 500 pages The other periodical, the *Review of Applied Entomology,* is brought out monthly in two series, one dealing with insects injurious to plants, the other with insects that disseminate human and animal diseases It summarizes all the papers or books concerning insects of economic importance published in any part of the world in any language It is interesting to note that, before the collapse of civilization in Russia, the abstracts of Russian articles were almost equal in number to those of the United States More than 1,000 periodicals are examined by the staff of the bureau, and the last volume contained nearly 2,300 abstracts The bureau has many other activities It has gradually collected a library of the utmost value which is card-catalogued It has prepared an analysis of the laws of the various countries with respect to the importation of plants which may bring with them new and dangerous pests By the aid of a donation from the late Mr Carnegie, it has sent students to study the methods of dealing with insect pests in the United States It has also sent investigators to tropical Africa who have under trying circumstances, done good work in connection with various disease-carrying insects Much of the work is too varied for detailed explanation and every year it increases At the present time the committee has under consideration a new activity—the supply of beneficial parasites to keep down insect pests The bureau is in effect a clearing house for entomological research It is financed by grants provided by the imperial government and the governments of the dominions, India and the colonies—forty governments in all During the year ending March 31, its receipts were $62,500 and its expenditure $55,000

When Is a Consultant Not a Consultant?

A dispute as to fees which ended in the court is of considerable interest A physician holding appointments at some

minor hospitals sued for the recovery of $655 fees claimed for visits at $10, consultations at $15 and attendance at an operation on the defendant's son for appendicitis, for which he charged $75. The defense was that the fees were unreasonable, as the work done was not a consultant's. Sir Thomas Horder gave evidence that a consultant's work consisted in seeing patients in conjunction with their family physician or by communication with him. But, being a registered practitioner, the consultant had the right to do the work of a family physician if he had the time and inclination. It was also within the right and privilege of the general practitioner, who possessed the personality and experience to do the work of a consultant. If a consultant did a general practitioner's work, it would not be fair to charge the same fees as if he were doing a consultant's work.

Sir Thomas thought that the plaintiff, in attending the defendant's son was acting in the capacity of a family physician. He found it difficult to give an opinion on the fee, but he thought that a reasonable one in the part of London in which the defendant lived would have been $5 before the war. There had been a recommendation that there should be an increase of 50 per cent, to which effect had generally been given. But when several visits were made in one day, $5 would be reasonable notwithstanding the 50 per cent. He did not consider that $75 for attending an operation was reasonable. In his opinion, $25 would be reasonable, and he would charge that himself. Mr. C. H. Pagge who performed the operation for appendicitis, said that he thought that the plaintiff was present in the capacity of family physician. His fee for the operation was $787. The defendant gave evidence that, in 1918, the plaintiff attended him on various occasions for a fee of $5 and that he was called in the capacity of a general practitioner.

Mr. Justice McCardie, in giving judgment, said the case raised a question of considerable importance to the public, namely, what fees a physician was entitled to charge in various circumstances. The defendant was a rich man but he fought the case as a matter of principle. His defense represented a protest by business wealth against the theory that a rich man should pay unusual fees. But the plaintiff contended (in substance) that a physician's fees should vary with the financial status of the patient. After the operation, the plaintiff paid forty-nine visits to the nursing home sometimes several in the day. For these, he charged $10 each. For the single day of the operation, he had charged $75 for attendance at operation, and $40 for four visits. On other days, he charged for four or three or two visits as the case might be at the $10 rate. The justice did not consider the plaintiff a consulting physician in the strictest sense which meant one who acted only in conjunction with the family physician. He frequently visited the houses of patients in much the same capacity as a general practitioner, charging the same rate of fees. The charge of $75 for attendance at the operation was excessive. Sir Thomas Horder, a physician of the greatest eminence, had said that he would not charge more than $25. The justice also thought that the charge of $40 for the four visits on the day of operation was excessive. He gave judgment for $465.

The Suspended Treatment of Venereal Diseases

In a valedictory presidential address at the seventh annual meeting of the National Society for Combating Venereal Diseases, Lord Gorell called attention to a problem that has been troubling every one concerned in the suppression of these diseases—the securing of continued treatment until the patient is cured. Statistics from hospitals and clinics disclose a very unsatisfactory condition. In some, the proportion of those who abandon treatment before cure is as high as 70 per cent. In this country, there is neither notification nor compulsory treatment of venereal diseases, such as exists in the British dominions and in foreign countries. The undue regard for the liberty of the subject, with corresponding want of regard for the welfare of the community, which is such a national characteristic and is so patent in neglect of vaccination is the obstacle. The ministry of health believes that the time has not yet arrived for any general system of compulsory notification.

Food Adulteration. The Use of Preservatives

An appeal to members of Parliament, urging them to protect food from adulteration and deterioration has been sent by medical, scientific, health, temperance, labor and philanthropic associations. The signatories include Sir H. Maxwell, chairman of the departmental committee on the use of preservatives and coloring matter in foods and vice president of the Bread and Food Reform League; Sir James Crichton Browne, chairman National Health Society; Professor Kenwood, chairman Council of the Royal Sanitary Institute; Dr. Beckett Overy, chairman Food Education Society; Dr. Alfred Cox, British Medical Association; Dr. Howart, president Society of Medical Officers of Health, and Dr. Still, chairman National League for Health, Maternity and Child Welfare. A manifesto in response to this appeal has been issued by members of Parliament of all parties. They will do all that they can to obtain for Great Britain the protection against food adulteration which has been secured by Canada, Australia and New Zealand, and will support legislation for a bread of high quality as to purity and nutrition. The dominions have already provided that the purchaser must be notified as to the amount of preservative in food which he buys. A considerable amount of illness may be due to this rarely suspected cause. There is evidence that boric acid, the most largely used preservative, has caused serious toxic symptoms in an appreciable proportion of children and adults. The list of foods containing boric acid is increasing and they are frequently consumed by infants and invalids on whom they may have an especially injurious effect.

The Profession and the Irregular Practitioner

The conferring of knighthood on Mr. Barker, the bone setter in recognition of his work as a 'manipulative surgeon' reported in a previous letter (THE JOURNAL, July 1, 1922, p. 52) has produced in the lay press a flood of denunciation of the prejudice, narrow mindedness and jealousy of the medical profession in refusing to cooperate with or recognize such a genius. In a letter to the *Times* Lord Dawson, physician to the London Hospital, combats such an interpretation. He considers that the cooperation of the profession with the callings ancillary to medicine should be encouraged and that we should never hesitate to seek the help of any worker, chemist, psychotherapist, masseur or healer when such help seems to be beneficial to the patient. There are no professional rules against this. But cooperation is one thing, admission to the responsibilities and rights of the profession is another. It takes years of hard and organized study to produce a physician. Efficiency is based on knowledge to reach which there is no short cut. Psychotherapists and healers for example, have certain specialized aptitudes, and some have brilliant gifts but they are not physicians. They can do excellent work in their own spheres and when cooperating with physicians. By all *means*, let us facilitate their doing so, and be open minded and *generous* in our bearing toward them. But sectional knowledge *must* be subordinate to the general knowledge of which *it is part*, those who have not the prescribed medical *training should* be under the guidance of those who have. A skilled masseur was asked for treatment by a *young man* suffering from abdominal pain. The treatment was *given in good* faith, but

without medical guidance The patient had appendicitis and nearly died In the interest of the public, the responsibilities of physicians must not be assumed by those without the prescribed training and qualifications The authorities cannot make exceptions It is not a question of conserving the privileges of a professional class, but a question of the public safety This country produces many men with the natural gifts of the sailor Imagine a gifted amateur wanting to captain a liner What would the board of trade say? 'Very sorry, but you have not the necessary training and certificates, and we cannot give permission" Does not the same apply to the human ship in its voyage across the sea of life?

PARIS

(From Our Regular Correspondent)

June 30, 1922

The United States and International Intellectual Cooperation

I mentioned in a previous letter (THE JOURNAL June 10, 1922, p 1828) that the council of the League of Nations had designated eleven members of the commission to study the question of promoting international intellectual cooperation The twelfth and last seat was reserved for an American scientist The general secretary of the league has just been informed that Mr George Ellery Hale, director of Mount Wilson Observatory and professor of astrophysics at the University of Chicago, has accepted the invitation to take part in the proceedings of the commission as the representative of the United States

Quinin Sickness of Occupational Origin

Drs Blamoutier and Joannon, interns of the Paris hospitals, observed in Dr Jeanselme's service a case of eczema that occurred in a workman employed in a quinin factory Several clinical and etiologic features of the case inspired them to study the frequency, the importance and the conditions of appearance of this occupational dermatosis The results of their research were published in the last number of the *Revue d'hygiene*

Three operations are necessary for the manufacture of quinin crushing of the cinchona bark to obtain cinchona dust, treating the powder with an oil and acid, and purification of the solutions of quinin salts, desiccation, pulverizing and packing These three operations are made in different parts of the factory by special workmen The first and second are made by men, and the third by women The three operations are not equally dangerous The dust from cinchona bark is liable to induce skin lesions, and these were quite frequent years ago when the crushing of the bark was made in the open At one time it even gave rise to serious complaints from workmen, and the factories were obliged to employ others to do the work Since the crushing machines have been covered, and the cinchona powder is piped through underground channels, these accidents are not so frequent About a fifth of the workmen employed in the second phase of the manufacture of quinin suffer from skin manifestations The third operation seems free of danger as eczema has never been observed among the women employed in drying and packing quinin salts This observation does not concur with reports from other writers who assert that workmen handling quinin sulphate are subject to skin eruptions The first evidence of illness is an eruption of the fleeting erythematous type accompanied by pruritus It appears in the folds (elbow, axilla, groin) and in the suborbital region, the skin becoming puffy and red It is in this last region that foremen look for evidence of the condition in new workmen, in order to detect sensitive subjects

The lesions disappear in a few days, if work is stopped The second stage presents the typical form, with acute eczema, edema, redness, vesiculation, oozing, secondary formation of scabs and intense pruritus When work is stopped, the symptoms disappear in about three weeks, but recurrence is inevitable if the subject persists in working in the factory Workmen are well aware of this phase of the disease, as a rule, when they have suffered from quinin eczema, they do not go back to the factory even to be paid off, but send their wives instead If the wife of a workman who has been forced to stop work for this reason is employed in the factory, she is obliged to leave the factory lest, through her, there be a recurrence of the husband's dermatosis The substances with which her clothes are saturated suffice to produce the condition, and long after the workman has left the factory, susceptibility persists in a latent state and flares up under a slight cause The case is cited of a workman who had suffered from quinin eczema but had not been working at the factory for several years, when he took a small dose of quinin for a slight illness, and a cutaneous reaction occurred The physician treating him was physician for the quinin factory, and he was unable to understand the case until he recalled the patient's history Newly engaged workmen who have not shown any sign of eruption after fifteen days are definitely immune Thus, it can be seen that there exists a sort of test which decides the workman's fate If there is susceptibility to quinin during the first week, it is never overcome, if there is no susceptibility, it is never acquired later

On the whole, the sickness is not an ordinary dermatosis due to an external cause, but is a real disease with skin manifestations It seems that cinchona dust acts as an anaphylaxis-inducing substance Is it possible to detect the predisposed? Blamoutier and Joannon recall the skin reaction mentioned by Boerner (THE JOURNAL, March 24 1917, p 907), and they question whether a similar test could not be applied to newly engaged workmen, to distinguish the sensitive subjects and discharge them before the appearance of the dermatosis On the other hand, it might be interesting to ascertain whether desensitization of subjects suffering from quinin sickness is not possible Blamoutier and Joannon are trying to accomplish this by the use of progressive small doses of quinin sulphate, but their experiences have not been decisive to date

The French Red Cross in Russia

In accordance with the agreement between the soviet republic of Russia and the French Red Cross (THE JOURNAL, April 29, 1922, p 1327) it has been decided that the French Red Cross mission will leave France for Russia about July 1 Nine thousand tons of various kinds of merchandise is being loaded in Dunkirk on the steamer *California* for Petrograd The general director of the Red Cross Monsieur *Hannonet* de la Grange, will be in Russia before the arrival of the relief ship

Death of Imbert

Dr Armand Imbert, former professor of physiotherapy of the faculty of medicine of Montpellier, died recently in Marseilles at the age of 71 He had been associate professor at Lyons and later professor at Montpellier, and was at the same time head of the service of electrotherapy and radiography of the Saint-Eloi Hospital His scientific works deal mostly with biologic physics In 1896, he introduced in the technic of radiography improvements which insured clearer pictures and admitted a considerable reduction of the length of exposure, which won him the Monthyon prize He also undertook a series of researches on physiologic optics, the mechanism of muscular contraction, phonation etc He was the pioneer in France in the study of the physiology of industrial work, and had the satisfaction of witnessing before his death the creation of laboratories for research on the subject that he was first to consider of scientific and practical value He was still devoting his time to these studies at

the time of his death Professor Imbert published the "Anomalies de la vision," a "Traite elementaire de physique biologique" and a "Traite elementaire de physique generale," the last named with the collaboration of Dr Bertin-Sans He wrote also a volume on "Observations economiques de vies ouvrieres" He has been national correspondent of the Academy of Medicine since 1899

The Centenary of Pasteur

A legislative bill that recently passed the chamber of deputies provides for the granting of an appropriation of 3,620,000 francs to enable the state to participate in the commemoration at Strasbourg of the centenary of Pasteur The committee delegated to inquire into the project has reported that the centenary of this great scientist should be celebrated not in Strasbourg alone but also in Paris and in various cities of Franche-Comte in which Pasteur lived—particularly, Dole, Lons-le Saunier Arbois and Besançon The committees on public instruction and public health, after hearing Monsieur Strauss, minister of public health, who spoke in the name of the government, reached the same conclusion and decided to request the government to modify the scope of the centenary by eliminating the two words "at Strasbourg" Acting on the suggestion of Monsieur Deville, in turn, the municipal council of Paris has unanimously voted an appropriation of 50,000 francs for the celebration at Paris of the centenary of Pasteur

A Medallion Cabinet at the Academy of Medicine

At the last meeting of the Academy of Medicine, Monsieur Hanriot announced that the academy proposed installing, in the hall of the immortals, a cabinet in which would be kept the medallions of members of this assembly

MADRID

(From Our Regular Correspondent)

July 1, 1922

Tribute to Cajal

Having reached the age limit, Prof Santiago Ramon y Cajal has retired as incumbent of the chair of normal histology and pathology of the Madrid Medical School The whole country has rendered tribute to the great scientist bestowing on him every distinction and honor, the greatest perhaps, being the award of the Echegaray medal This was presented to him in the Royal Academy of Sciences by the king, who delivered a speech overflowing with respect and love for the illustrious Spaniard, who has brought so much prestige to his country A number of cities have designated Ramon y Cajal as their adopted son, many others have named streets after him, and prizes have been established in his name The government performed an act of greater importance in introducing a bill for the construction of a building for the Cajal Institute which was organized, Feb 20, 1920 The bill carries an appropriation of a million pesetas ($155 400), divided into four sums which will be spent annually from 1922 to 1925 on the building designated as Cajal's Biologic Institute An appropriation of 50,000 pesetas ($7,770) a year is made for maintenance, including the 10,000 pesetas ($1,540) now provided for Cajal's laboratory The work of the institute will be directed by a board of trustees presided over by Cajal

Death of Dr Azua

Dr Azua professor of dermatology of the Madrid Medical School and physician to the San Juan de Dios Hospital, is dead Dr Azua was an outstanding personality his authority as a dermatologist and scientist being acknowledged by all He was a *self-made man, unhampered by his environment* who began his career with a struggle against the dermatologic views prevailing at that time The French doctrines of the dyscrasias held full sway in Spain, and as a protest he leaned toward the pathologic and localizing theories of the Vienna school With his enthusiasm for concrete facts positive data and experimental control, he opened a common sense path which future generations may follow, and for this the younger physicians are grateful No practicing physician had a reputation comparable to Azua's, whose enormous practice brought him a fortune He was trained by his experiences in the San Juan de Dios Hospital one of the leading institutions devoted to venereal and skin diseases His merit was so well known that, in spite of the jealousy always shown by the Madrid University toward hospital physicians, a special chair was created by the minister of education and Azua became the first Spanish professor of dermatology and syphilology This creation of a professorship by a minister, while it turned out well in Azua's case, was later abused, and it has been one of the causes of the decline of the medical school, as the only qualification enjoyed by *several professors appointed in this way* was the minister's friendship Through Azua's single-handed efforts and determination, the *Spanish Dermatologic Society* was founded A few days before his death, he had submitted to the National Academy of Medicine the text of his reception speech, and not long ago a group of South American physicians presented him with a testimonial of their admiration

Fiftieth Anniversary of Espina y Capo

Dr Espina y Capo a specialist in chest diseases, has celebrated his "golden wedding" with medicine The medical profession showed its admiration and love for the old master by *ordering a marble bust* which was unveiled with proper ceremonies in Ward 27 in the General Hospital of Madrid, where Dr Espina practiced for many years The provincial board, which has general supervision over the hospital attended in a body The medical profession in spite of its quarrels and passionate disputes, is the one in Spain which knows best how to honor its prominent representatives There are at present in Madrid not less than ten marble and bronze statues of physicians Benavente, Federico Rubio Eugenio Gutierrez, San Martin Pulido, Achucarro, Cortezo, Esquerdo, Espina y Capo and Ramon y Cajal Dr Espina y Capo has been a great popularizer of his selected field, a noted orator in the National Academy of Medicine and the Public Health Association and in the senate where he cooperated in the enactment of sanitary legislation He is also one of the leaders in the antituberculosis campaign, and the highest authority on this disease in Spain

BERLIN

(From Our Regular Correspondent

July 7, 1922

A Prussian Institute for the Study of Problems of Air Hygiene

In 1901, the Prussian government, having in mind the contamination that drinking water and water used for other purposes undergo created in Berlin an experiment station for the study of water problems, including the best means of disposing of sewage waters In 1913 an institute known as the Landesanstalt fur Wasserhygiene with headquarters of its own at Dahlem near Berlin, was established The function of this central station was to study from hygienic and economic standpoints the problems pertaining to the securing of adequate and satisfactory water supplies and the disposal of sewage and waste products in general The institute was, in this connection, to conduct researches and to perform tests of general value and interest It was to accept any commissions imposed by the various ministries, and

minor researches were to be made for officials and private persons, for which a definite fee was chargeable Furthermore, it was to furnish central authorities with information and issue certificates or testimonials in the interest of public welfare

The present director of the institute, Geheimrat Beninde, member of the Prussian ministry of public welfare, has recently issued a statement in which he recommends that the activities of the institute be extended so as to include researches on problems pertaining to air hygiene Not only the water supplies but also the air is being greatly contaminated by the enormous development of modern industry, and this contamination is exerting an effect on plant and animal life, and more particularly, on the hygienic conditions under which mankind lives He points out that contamination of the air through industrial plants and the various mechanisms of modern life may be classified under two main heads, through (1) gas, and (2) dust In the air are found more or less large quantities of carbon dioxid gas, which results from putrefaction and fermentation processes, and carbon monoxid from imperfect combustion of fuels, being found in considerable quantities mixed with the gases of blast furnaces and the smoke from chimneys Chlorin is found in the air in the vicinity of certain factories, likewise hydrochloric acid sulphurous acid, sulphuric acid, hydrogen sulphid, volatile fatty acids and other foul smelling gases develop under various fermentative processes Various forms of air dust have also developed with the increase of industry and traffic Most prominent are smoke and soot, the products of incomplete combustion of coal The relation of air contamination to disturbances in the human organism is a well known chapter in pathology, more particularly the part played by air contamination in the causation of occupational diseases In view of the facts, the Prussian government has already approved Director Beninde's plan and has taken the necessary action to put the Landesanstalt fur Wasserhygiene in a position to undertake researches in the domain of air hygiene

Excess of Male Births

In a previous letter I referred to the question of an excess of boy babies and recently Dr Hartmann brought up the subject again, citing statistics in proof of his opinions In the period from 1915 to 1920, it appears from the records that the excess of boy births materially increased, for example, in Prussia the excess of boy babies over girl babies was 7 2 per cent, as compared with an excess of 6 2 per cent for the period 1910 to 1915 In 1919, the excess amounted to 8 6 per cent In Saxony the excess amounted in 1917 to 8 2 per cent, and in 1919 to 9 2 per cent In Bavaria, the excess for 1918 was 8 8 per cent, for 1919, 8 5 per cent, as compared with an excess of 6 2 per cent for the period 1910 to 1917

Statistics on Prostitution

The Munich physician Dr Marcuse gave here recently a report on the nature and spread of clandestine prostitution in Munich Of 832 clandestine prostitutes who were rounded up by the police in Munich, 438 were affected with venereal disease 271 of them for the first time Of these 832 girls, 333 had been brought up in the city, while 467 were from rural sections (which leaves thirty-two unaccounted for) Of the 832 delinquents, 607 declared that they had no regular means of livelihood, 130 belonged to the 25-30 age group, 260 to the 20-25 group, 256 to the 15-20 group, while five were under 15 years of age Alcoholism in the family history was noted in 195 cases, insanity in fifty-one cases, and epilepsy in twenty cases In the case of fifteen, the ancestors had suffered from nervous diseases, while, in sixty-one cases, both parents of the girls had been affected by some predisposing malady

Marriages

JAMES ALEXANDER WADDELL, University, Va, to Miss Mary C Graves of Somerset, Va, June 27

ARTHUR C KNIGHT, Philipsburg, Mont, to Miss Karen Hansen of Wilbur, Wash, June 29

JOHN JULIAN CONNELLY, Rockville, Ind, to Miss Harriet Hubbard of Indianapolis, recently

AUSTIN INGRAM DODSON, Richmond, Va, to Miss Louise Barham of Emporia, Va, June 6

JOHN KIRK RICHARDSON to Miss Irene Trotter Geisinger, both of Richmond, Va, June 12

CARLISLE CALAHAN COCHRAN, Huntersville, N C, to Miss Adelia John Everette, June 6

WALTER MCBETH, Royal Center, Ind, to Miss Julia Faye Frye of Adams, Ind, June 28

PARKS M KING, Charlotte, N C, to Miss Anna Howerton of Lexington Va, June 27

ROBERT H BELL to Miss Minnie E Dilks, both of Carlinville, Ill, June 6

Deaths

Frank Lester Morrow, Braddock, Pa, University of Pittsburgh School of Medicine, Pittsburgh, 1913, member of the Medical Society of the State of Pennsylvania, aged 33, was instantly killed, July 5, when the automobile in which he was driving a patient to the hospital was struck by a Baltimore and Ohio express train

Laughlin O'Neal Malsbury, Peru, Ind, Kentucky School of Medicine, Louisville, 1891, member of the Indiana State Medical Association, formerly secretary of the Miami County Board of Health, at one time a member of the city council, died July 5, in Chicago, aged 54, from toxicemia caused by ischiorectal abscess

Charlotte Steckel Farrington, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1901, member of the Medical Society of the State of Pennsylvania and the Philadelphia Psychiatric Society, died, July 12, at the Presbyterian Hospital, aged 52, from heart disease

Robert Rice, Haverhill, Mass, Hahnemann Medical College and Hospital of Philadelphia, 1908, member of the Massachusetts Medical Society, on the staff of the General Stephen Henry Gale Hospital, where he died, July 9, aged 50, following a long illness

Clayton W Russell, Springfield, Ohio, Eclectic Medical Institute, Cincinnati, 1890, member of the Ohio State Medical Association, formerly president of the Ohio Eclectic Medical Association, died, July 13, aged 56, from heart disease

James Eddy Blake ⊕ Whitestone, N Y, Columbia University College of Physicians and Surgeons, New York, 1898, University of Bonn Germany, 1902, also a member of the New Hampshire Medical Society, died July 18, aged 49

Lauriston M Berry, Guernsey, Wyo, University of Vermont College of Medicine, Burlington, Vt, 1869, member of the Wyoming State Medical Society and the Massachusetts Medical Society, died, July 6, aged 80

George W Metzger, Hughesville, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1866, member of the Medical Society of the State of Pennsylvania, Civil War veteran, died, July 7, aged 81

Edward Ashby Waugh, Lynchburg, Va, University of Virginia, Department of Medicine, Charlottesville, Va, 1883, member of the Medical Society of Virginia, died, July 9, aged 69, from angina pectoris

Albert Henry King, West Palm Beach, Fla, Cincinnati College of Medicine and Surgery, 1901, member of the Florida Medical Association, died, June 30, at Asheville, N C, aged 45

⊕ Indicates Fellow' of the American Medical Association

Frances W. Boyer, Pottsville, Pa., University of Pennsylvania School of Medicine, 1868, formerly president of the Milliken Hospital board, died suddenly, July 11, in Germany, aged 73.

George M. Bell, Wakefield, N. C., College of Physicians and Surgeons, Baltimore, 1880, member of the Medical Society of the State of North Carolina, died, May 18, aged 66.

James Marcus Everett, De Kalb, Ill., Rush Medical College, Chicago, 1877, member of the Illinois State Medical Society, died, July 6, aged 69, from interstitial nephritis.

Arthur Reeves, Oberlin, Kan., Ensworth Medical College St. Joseph, Mo. 1910, member of the Kansas Medical Society, died, July 7, aged 38, from appendicitis.

Willis E. Kennemur, Sulphur Springs, Texas, Medical Department, University of Louisville, Louisville, Ky., 1894, died, July 3, aged 56, following a long illness.

Caroline Eliza Hastings, Sharon, Mass., New England Female Medical College, Boston, 1868, died, July 10, aged 80 at the Massachusetts Homeopathic Hospital.

Daniel Albert McCarthy, Troy, N. Y. Albany Medical College, Albany, N. Y. 1899, formerly city physician, died June 16, aged 44 at the Troy City Hospital.

Francis Pierce Silva, Boston, Medical School of Harvard University, Boston 1893, member of the Massachusetts Medical Society, died, July 13 aged 52.

Joseph Benedict Lyons, Boston, Medical School of Harvard University, Boston 1894, member of the Massachusetts Medical Society, died, July 18, aged 50.

Charles William Buchanan, Jr., Toronto, Ont., Canada, University of Toronto Faculty of Medicine Toronto Ont., Canada, 1865, died, May 20, aged 84.

John D. Jay, Pera, Ala. (licensed Alabama, 1888), member of the Medical Association of the State of Alabama, died July 14 aged 81, from senility.

Thomas F. Flaherty, Massey Station, Ont. Canada Western University Faculty of Medicine, London, Ont., Canada, 1895, died, May 7, aged 53.

Clara A. Hovey ⊕ Chicago, College of Medicine and Surgery (physiomedical) Chicago, 1903, died July 16, aged 66, from cerebral hemorrhage.

John J. Meigs, Stockton, Calif., Medical School of Harvard University Boston, 1860, died, July 6, aged 83, at St. Francis Hospital, San Francisco.

Oscar B. Stafford, La Salle, Ill. (licensed, Illinois, 1877), died, July 6, aged 82, at the People's Hospital, Peru, Ill. following a long illness.

Edward C. Wagner, Wilkes-Barre Pa., University of Pennsylvania School of Medicine, 1890, died July 9 aged 66, from heart disease.

Joseph Roy Hawley ⊕ Chicago, Northwestern University Medical School, Chicago, 1893, died, July 20, aged 50, from chronic nephritis.

Henry Clay Rose, Dayton, Tenn., University of Nashville Medical Department, 1874, died July 4, aged 72 following a long illness.

Charles Williams, House Springs, Mo. St. Louis Medical College, 1872, died, July 8, aged 75, from cerebral hemorrhage.

Christian Emil Stafrin ⊕ Portland, Ore., University of Oregon Medical School, Portland, 1911, died suddenly, July aged 46.

Emily Metcalf Thurber, Providence, R. I. Boston University School of Medicine, Boston 1878, died, June 30 aged 85.

Hiram S. Chapin, Holder, Ill., Rush Medical College, Chicago 1872, died, July 9 aged 73, from chronic arthritis.

Marion Holland, Cassopolis, Mich., University of Michigan Medical School, Ann Arbor, 1875, died July 3, aged 70.

George W. Barkman, Govans, Md., College of Physicians and Surgeons, Baltimore, 1881, died, July 11, aged 71.

Joseph H. Lurie, New York, University of Berlin, Germany, 1875, died, July 9, aged 74 from heart disease.

John Ward Willson, Baltimore, Baltimore University School of Medicine, 1889, died June 24, aged 77.

Albert Franklin Bonney, Buck Grove, Iowa (licensed, Iowa, 1889), died, June 30, aged 68, from uremia.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

THE AMERICAN MEDICAL LIBERTY LEAGUE

It was in 1910 that the speciously named "National League for Medical Freedom" began its intensive campaign against scientific medicine in general and the American Medical Association in particular. Engineered and inspired by nostrum exploiters and those opposed to pure food laws, aided and abetted by the followers of the various cults, the League for Medical Freedom blazed its rocket-like course across the medical firmament—and in due time the stick came down! Doubtless there was good money in it for some one while it lasted. Tens if not hundreds of thousands of dollars, were expended in newspaper advertising alone. But its effort was abortive because it was fundamentally wrong-headed and the good sense of the American people penetrated the motives that were behind it.

It is some time since we have heard of the "National League for Medical Freedom", today there is another organization less heavily financed, but still, doubtless, producing a living for those who engineer it. It is the American Medical Liberty League,' with headquarters in Chicago. This concern does little, if any, newspaper advertising. It does, however get out a set of leaflets and pamphlets and those who are for one reason or another, opposed to scientific medicine, purchase these leaflets and distribute them.

SOME LIBERTY LEAGUE LITERATURE

As indicative of the type of "literature" thus issued, the following partial list is given.

Medical Health Officers Syphilizing the Nation." This leaflet declares that all vaccine virus shows the reaction of congenital syphilis and 'even the vaccine scars show its contamination.' The leaflet quotes as its authority for this charge Albert Abrams, A.M., LL.D., M.D. (Heidelberg), F.R.M.S. Price, 45c a hundred.

Toxin-Antitoxin—How It Kills and Cripples Children." Purports to be a Detailed Story of the Horrible Results Following a Texas Serum Campaign." Price, $1.00 per hundred.

The American Medical Liberty League." Professes to tell what the League' is, "Why you need it" and, in large bold-faced capital letters, 'HOW TO WORK IT!" Only 40c a hundred.

The Going of Cumming." Said to be "Paragraphs on the Enlightenment on Calf Pus Cult", in reality, a tirade against Surgeon General Hugh S. Cumming. They come at 70c a hundred.

Know the Facts About Vaccination." An alleged compilation of 'statistics and expert testimony' brought together by Lora C. Little (of whom more later) and reprinted by permission from Dr. George Starr White's (of whom, also, more later) Lecture Course to Physicians." Ten cents a copy.

These are but a few of the pieces of propaganda that are being sent out by the "American Medical Liberty League." At their headquarters they will also hand out to those interested a reprint from the *Lindlahr Magazine* (the house organ of a so called 'nature cure institute") telling of the marvels of the electronic diagnosis and treatment' of Albert Abrams! They hand out too, the *Central States Osteopath* the official organ of the Illinois and Wisconsin osteopaths.

SOME INQUIRIES

During the past two or three years inquiries have been received relative to the League." A physician, health officer in a Virginia city wrote:

> I enclose a leaflet of the American Medical Liberty League Chicago, Ill. This leaflet was submitted to a local paper as an advertisement to be charged to the account of a chiropractor of this city. The news paper informed me that it has refused to publish it. I am interested not only in the anti-vaccination propaganda of *this leaflet*, but also am pleased that the newspaper should have refused to publish it.

This from the state health officer of a southern state

Will you please advise me as to the cult Mrs Little represents?

These are representative of inquiries received The American Medical Liberty League was brought into existence in the latter part of 1918 Lora C Little seems to be the moving spirit of the organization and appears officially as its "secretary" In November, 1918, Mrs Little sent out a mimeographed letter headed "STRICTLY PERSONAL AND CONFIDENTIAL" It was to the effect that with the coming of peace there would 'burst forth" what was described as "long-pent feeling over medical outrages, committed wholesale the past two years " Further, this bursting would give a grand opportunity to the believers in 'medical freedom" to make a killing 'Two big things" would be necessary to "meet the situation" first, "a full exposure, backed by an array of authentic facts" which must be, 'when the proper time has

Reproduction (reduced) of the letterhead of the Ensign Remedies Company a concern which sells cures for Disappointment in Love Floating Kidney Laziness Locomotor Ataxia' and many other conditions

come, widely distributed", second, "a definite program of action"

Then came the nub To accomplish these "two big things" funds were required, hence, the appeal for "membership" in the American Medical Liberty League, price $2 00 a year "which covers subscription to the *Truth-Teller*" According to Mrs Little, ten individuals in any locality who join the 'League" and pay their annual fees may organize a "Local League"

THE "TRUTH-TELLER"

Before dealing with the personnel of the founders of the League, which in itself is interesting something should be said about the "League's" official organ, the *Truth-Teller*—ironical name! This somewhat lurid sheet is "published semimonthly by the Truth-Teller Publishing Company at 38 N Division St, Battle Creek, Mich" The Battle Creek telephone directory does not show any company of this name but it does show the "Ensign Printing Co" at 38 N Division St The editor of the *Truth-Teller* is W S Ensign—of whom more later—who puts after his name the mystic abbrevation "Phys et Pat Ch" Its "Associate Editor" is Wilhelm Heinrich Schwartz, M D , its "Managing Editor' is D W Ensign and its "Traveling Representative" is Thomas D Ensign, in short, it seems to be largely an Ensign publication The *Truth-Teller* keeps no subscription books but, if you receive a copy of it regularly, "you can rest assured that the subscription price of same has been paid" The *Truth-Teller* was previously *The Peril* ("America's Weekly Journal Devoted to Homeopathy and Humanity") which, in turn, was originally known as *America's Homeopathic News* edited by Wilhelm Heinrich Schwartz, M D , "Vice-President of International Anti-Vivisection and Cruelty to Animals Congress, etc etc

But, to get back to the American Medical Liberty League In the "Strictly Personal and Confidential' letter previously referred to, the officers of the 'League' were given as follows

President—Charles M Higgins
Vice-President—Eli G Jones
Secretary—Lora C Little
Treasurer—D W Ensign
Director—J H Greer
Director—W S Ensign
Director—J W Griggs

CHARLES M HIGGINS, Brooklyn, New York This gentleman was, if he is not still, the treasurer of the "Anti-Vaccination League of America," and a somewhat active member of the "National League for Medical Freedom' He is or was, a member of the "Vivisection Investigation League," and the 'New York Anti-Vivisection Society" He published a sixty-four page pamphlet ("with exhaustive index, 10c, post paid") entitled 'The Crime Against the School Child," which advised the public 'how to legally defeat vaccination, the medical evil which now kills more children than smallpox" This was advertised in the *Truth-Teller* In 1917 Higgins also issued a twenty-four page pamphlet entitled 'Restore the Coroners, Check Dangerous Medical Domination, and Protect Public Life and Safety"

ELI G JONES, Buffalo, New York Dr Jones was graduated fifty years ago (*1872*) by Dartmouth Medical School He was for some time "President" of the egregious "American Association of Progressive Medicine" A few years ago he was sending out circular letters to physicians offering to teach—for a consideration—his method of curing cancer Dr Jones claimed to cure 80 per cent of all cases of cancer that he treated In his letters to Ohio physicians he gave the name of Dr C S Carr of Columbus, Ohio, as a reference Carr was Peruna's advertising expert and ran a little medical mail-order concern of his own as a side line Carr also published a freakish publication known as the *Columbus Medical Journal*, in which periodical Eli G Jones told about his "cures" for cancer, and numerous other things and in which the Ensign Remedies Company advertised and to which W S Ensign contributed Of course Dr Jones was a member of the National League for Medical Freedom" when that institution was in existence According to a character sketch published in the *Truth-Teller*, Dr Jones "has at different times practiced Allopathic Eclectic, Homeopathic, Physio-Medical and Biochemical medicine" We can easily believe it

LORA C LITTLE Mrs Little, who seems to have had much to do with the organization of the League" apparently hailed from the Pacific coast, where she was a traveling lecturer whose business it was to create sentiment against vaccination. Mrs Little contributes prolifically to the "League's" house-organ, the *Truth-Teller* In addition to being "Secretary" of the American Medical Liberty League, Mrs Little was also 'Secretary" and "Official Organizer" of the "Central Health Committee of the State of Illinois" There was the usual proportion of names of chiropractors and osteopaths on the letterheads of the official stationery of the "committee" This "committee," too, solicited funds—"for the purpose of

DOCTOR I teach physicians (by mail) my method of treating cancer tumors malignant growths both external and internal. This method of treatment has stood the test of nearly forty years practice.

I have a record of permanent cures of genuine cancer made fifteen to twenty four years ago and there has been no return of the disease I want some good reliable physicians who are willing to learn and are ambitious to do things.'

The best of references to physicians and patients. Address for further particulars

ELI C. JONES M D
85 Bayard St. New Brunswick N J

In this advertisement (nearly as large again in the original) published some years ago Eli C Jones described his mail order course in curing cancer

securing medical liberty in the new Illinois constitution'—and made a special plea that the persons circularized should help secure, for a delegate to the Constitutional Convention, the nomination and election of Frederick A Freeark, a Chicago lawyer who would 'stand to the last ditch for our principle" Mr Freeark's name appeared later as one of the 'directors" of the "American Medical Liberty League" He was not elected

D W ENSIGN, Battle Creek Mich Mr Ensign was "Business Manager and is now 'Managing Editor' of the *Truth-Teller* Enough said

J H GREER, Chicago Dr Greer was graduated in 1875 by the Bennett Medical College, then an eclectic institution For many years he conducted the 'Harvard Medical Institute' in Chicago and specialized in genito-urinary work In 1910 the United States immigration officials on the Canadian border

wrote for information regarding J H Greer, stating that a number of aliens had received Greer's advertisements and sought entry into the United States for the purpose of treatment Some of these aliens sent to the immigration service letters which they had received from Greer, together with some of Greer's advertising matter Greer, it seemed, issued a booklet entitled "A Peep at the Mysteries of Nature" whereby he drummed up trade Greer also urged some of his prospective mail-order patients to purchase his book "A Physician in the House" As Greer put it

> If you cannot come and see me treat yourself This you can do with the aid of my book A Physician in the House Get a copy of it, study it carefully and apply it exactly and watch your pains and aches vanish like an ugly dream at dawn"

According to a prospectus of this book "It opposes medical fads of all kinds, and makes uncompromising WAR ON VACCINATION, and the use of ANTITOXIN" Furthermore it was

W H SCHWARTZ, M D — Assoc te Edito
D. W ENSIGN — M nag r T ll r (A ociate)
THOS. D ENSIGN — Travel g Represent tive

It will be noticed that the Truth Teller seems to be a family institution

said to contain 'Valuable INFORMATION for the MARRIED" Greer claimed that he did not guarantee cures "except in surgical cases, such as varicocele, hydrocele, hernia, fistula hemorrhoids, and stricture, etc"

ENSIGN'S CURE FOR BASHFULNESS, ETC

W S ENSIGN Phys et Pat Ch" Battle Creek, Mich Mr Ensign is Editor of the *Truth-Teller* and, with Mrs Little, apparently an important factor in the American Medical Liberty League Presidents vice-presidents and treasurers seem to change, as do also some of the directors, but through all W S Ensign and Lora C W Little continue as Editor" of the official organ and Secretary' of the organization, respectively W S Ensign for some years has been doing a mail-order business in Ensign Remedies The Ensign Remedies, according to Ensign, are good for whatever ails you Apparently, there are about one thousand of them and they are known by numbers Ensign therapy is a comparatively simple study

A booklet issued by the Ensign Remedies Company lists all Diseases and Their Cure" These are arranged alphabetically from "Abdomen," Abortion" and "Abscess" through 'Ecchymosis,' "Eclampsia," 'Eczema" and "Iritis," 'Irritability," "Itch" to 'Worms ' 'Wrinkles" and Writers' Cramp" It is all very easy For Peritonitis, take '748A and B", for Alcoholism, 'Topers should use No 17", for Appendicitis, Use No 758A and B for the acute attack", for Diphtheria, No 675A and B is our specific treatment Do not use anti-toxin" Should you have Atrophy of the Optic Nerve, take "No 521A and B", for Cataract, No 504A and B" are indicated Yellow Fever calls for No 1066A and B' and Angina Pectoris for 342F" Bright's Disease is cured with '854A and B," but be sure you have the figures right as "No 857A and B" is for Floating Kidney For Lockjaw try 'No 34" and for Locomotor Ataxia No 260A and B" "No 1019A and B" are for Housemaid's Knee

But the Ensign Remedies are good for more than physical ailments, 'in the absolute cure of diseases of the mind nothing equals the Ensign Remedies" Are you troubled with Bashfulness," take No 186A and B", do you see Animals or Reptiles" (presumably of the pre-Volstead era) try No 187A and B' For Dullness and Stupidity, No 189 A and B", for Disappointment in Love, No 192A and B" For mere 'Laziness Lack of Ambition No 196A and B', should you have a Desire for Light and Company" take 'No 197A"

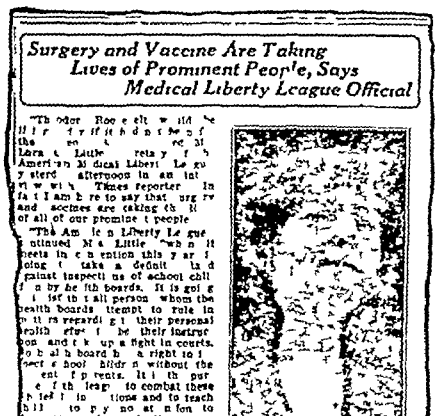
A few years ago the state officials of Michigan sent for some of Ensign's various cures and analyzed them and published the results in the official bulletin "Fakes and Frauds" Ensign's "Appendicitis Cure" was reported to show on analysis sugar 100 per cent , Ensign's 'Pneumonia Cure" was another 100 per cent sugar product, while Ensign's "Hay Fever Cure" had the same composition The Michigan authorities unkindly called attention to the fact that while these remedies sold at $1 00 each, their estimated cost was less than 1/10 of a cent It is only fair to state, however, that since these analyses were made the price of sugar has gone up

J W GRIGGS, Minneapolis, Minn Mr Griggs, was, if he is not still vice president of the "Anti-Vaccination League of America"

THE STATE VICE-PRESIDENTS

The 'League" also has 'State Vice-Presidents" In 1920 forty-five states were represented, in 1922 this list had dwindled to thirty-six This doubtless is an index of the waning interest in the "League" It would consume too much space to take up the various individuals whose names appear as state vice-presidents and publish the details on file regarding these persons However, it will not take much space to give a brief sketch as revealed by the Propaganda files of the State Vice-President of California, Dr George Starr White

GEORGE STARR WHITE, M D, F S Sc (Lond), Los Angeles Calif White who was the 'Second Vice-President" of the Allied Medical Associations in 1918, was graduated in 1905 when he was forty-two years old, by the New York Homeopathic Medical College and Hospital He seems to have been one of the proponents of Albert Abrams' 'spondylotherapy" and of Fitzgerald's 'zonetherapy," etc , and in 1915 it was announced that he would give one week courses to physicians in Spondylotherapy" at Chicago, Kansas City and Denver, respectively In May, 1915, White was arrested in Chicago



Surgery and Vaccine Are Taking Lives of Prominent People, Says Medical Liberty League Official

MRS LORA C. LITTLE

Reduced reproduction of part of a news story in a Davenport (Ia) paper relative to Mrs Little's appearance before the chiropractors Mrs Little was reported as stating that practically all newspapers are under the control of the medical trust

and fined $100 and costs for practicing medicine without a license Dr White's specialty seems to be picturesquely known as Bio Dynamo-Chromatic-Diagnosis" This is described by one of its enthusiastic adherents as 'Diagnosis by Sympathetic Vagal-Reflex" To obtain the 'Sympathetic Vagal Reflex it seems the patient must face east or west and have his bare abdomen percussed until a dull area is located The patient is then faced north or south and again percussed Then, it seems, different colored lights are thrown on the patient the location of the areas of dulness being determined meanwhile A combination of ruby and blue light "will

cause a reflex in cases of gonorrhea," a "green light will cause a reflex in cases of liver or gallbladder trouble," while the color for carcinoma is orange red! During the height of the influenza epidemic White took a flier in nostrum exploitation, putting on the market "Valens Essential Oil Tablets" which were for "Gripping the Flu out of Influenza," and were also said greatly to benefit or cure incipient tuberculosis, hay-fever, asthma, and "catar" (White affects simplified spelling) The letters "F S Sc, Lond," after Dr White's name carry with them an air of erudition and mystery that is well worth what they cost They mean "Fellow of the Incorporated Society of Science, Letters and Arts of London, Ltd" The "Fellowship" is held by not a few "patent medicine' exploiters in the United States It costs one guinea!

Here, then, we have brief sketches of those individuals who were mainly instrumental in bringing into existence the 'American Medical Liberty League" The facts brought out are sufficient to permit the physician and the intelligent layman properly to evaluate the activities of this organization which professes to have for its main object the protection of the public The "American Medical Liberty League" like its prototype, the "National League for Medical Freedom" will flare, sputter—and go out!

Correspondence

THE CASE OF WILLETTA HUGGINS

To the Editor —Now that Professor Jastrow has so ably disposed of the case of Willetta Huggins by stating that the medical profession has the "will to believe," there remain a few other questions to be disposed of

How does it happen that her case was diagnosed by the psychologic department of Wisconsin as "almost a moron"? Do any of the physicians who saw her in Chicago or Evanston think her a moron?

How does it happen that the psychologic department of Northwestern University has no instrument fine enough to determine her threshold of feeling?

How does it happen that she distinguished blue, yellow and green in a mixture of blue and yellow that to a normal eye appeared green only?

How does it happen that she distinguished between the streaks of pink and green feldspar? Her vision would seem to be abnormally acute instead of being, as every one admits, much below par since early childhood, if Professor Jastrow's explanation is correct

If she distinguishes light rays of different wave length by the sense of smell, how can she be expected to distinguish between light rays in the dark where there are no light rays?

Lastly, has not Professor Jastrow heard how the psychologic department of Cornell, and the rest of the faculty for that matter, were so taken in by an exposition of Freud and his theories, given by an agricultural student who had not heard of Freud a week before that they kept him talking an hour and answering questions for a longer time and were so enthusiastic over his exposition that they had him repeat the lecture? It really seems as if the medical profession had no monopoly of "the will to believe"

THE DEATH OF JOHN SHELL

To the Editor —Fakes die hard, especially a fake which a veracious press is interested in keeping alive I exposed the John Shell "the oldest man in the world" fake, in a magazine article, in the New York *Sun* two years ago I showed then, through the census records, that Shell was less than 100 According to these records, which I obtained through the courtesy of Hon S L Rogers, director of the census, Shell's age in 1860 was given as 37 In 1870 his age was 48 In 1880, 58, in 1890, 67 In 1900 his age was 78, his birthday being given as May, 1822 I visited him in November, 1919 At that time I tried to verify the age, and saw his oldest son his great-grandson, his father-in-law, who was his nearest neighbor and knew him for more than fifty years, his lawyer of thirty years ago, an ex-judge who stopped at Shell's house in the early eighties, a physician who treated him the preceding winter, and the present circuit judge All agreed that Shell was about 100 His son and great-grandson said he was less than 100 The details of the scheme by which the exploiters of the old man made several thousand dollars by exhibiting the senile dement as the oldest man in the world have no medical interest aside from the production of an obsession through suggestion

I L NASCHER, M D, New York

DO AMERICAN INDIANS HAVE CANCER?

To the Editor —In THE JOURNAL, July 8, Dr Joseph Rilus Eastman discusses interestingly the subject of malignant growths I wish, however, to comment on his statement that our American Indians do not have cancer Here in the Southwest I have known fairly well one tribe of Indians They number about 500 During my residence of three years among them, three full-blood Indian men died of cancer, respectively, of the lips and mouth, of the throat and of the penis For the last eighteen months at Tucson I have had charge of another group of about 500 Indians During this time one of them, a woman of pure Indian extraction, died of cancer which destroyed the right orbit and adjacent tissues It seems to be the custom not to perform necropsies on Indians, and I believe that few, if any, have been performed If any considerable number of necropsies were performed, perhaps there would be disclosed occasionally a deep seated cancer

C G ANDREWS, M D, Tucson, Ariz

LETTER ON THE DEATH OF KEATS

To the Editor —The following extract from the letter of Joseph Severn, dated Rome, Jan 11, 1821, written in the sick-room of John Keats (whom Severn was nursing in his last illness) may prove of interest as showing how the Italian medical authorities viewed tuberculosis a hundred years ago

News was brought me the other day that our gentle landlady had reported to the police that my friend was dying of consumption Now their law is — that every individual thing even to the paper on the walls in each room the patient has been in shall without reserve be destroyed by fire the loss to be made good by his friends This startled me not a little for in our sitting room where I wanted to bring him there is property worth about £150, besides all our books etc —invaluable

J R CLEMENS, M D, St Louis

Mosquito Destruction by a Plant —According to investigations carried out by Dr Arturo Caballero, professor of botany in the University of Barcelona, in the summers of 1919-1920, *Stegomyia, Culex* and *Anopheles* larvae die in any water where the plant known as *Chara foetida* is found The larvae die quicker if they are young and those fresh from the egg do not last over an hour These laboratory experiments were later tried out in the field with the species *Chara foetida, Chara contraria* and *Chara hispida* Caballero suggested at first that the larvae died because of the film formed on the surface of the water by the plant in question, but further experiments showed that they also died if the film was removed He suggested therefore, that the death of the larvae is produced by some toxic substance segregated by the *Chara* plants The plant spreads rapidly in the water and seems to last indefinitely Dr Caballero has published several articles on this subject, one of them in the *Revista de Higiene y Tuberculosis* One of his early papers was recently reprinted by the Mexican Health Department

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

MECHANICAL BUST DEVELOPERS

To the Editor—In catalogues of medical and surgical supplies one sees listed among standard cupping apparatus so called bust-developers consisting of a glass portion designed to fit the organ with a suction apparatus at the other end I assume that the supposed function of this apparatus is to bring about through hyperemia a permanent enlargement of the female breast For many years I have been investigating the general biology of secondary sexual characters of the organism and I should like to know whether there is any valid published evidence that the pieces of apparatus mentioned above can or do bring about any such a result as that suggested It seems to me on biologic grounds very doubtful I shall be greatly obliged if you will give me references to any pertinent literature If my assumption as to what these pieces of apparatus are made (and presumably old) for is wrong will you please tell me what their use and effect is? P

ANSWER—There is apparently no scientific evidence to indicate that the devices described actually induce growth of the organs concerned Rhythmic irritations of the lactating breast, as from a breast pump or by massage, will unquestionably stimulate the circulation of the breast with a possible increase of the flow of milk There is, however no procedure that will produce a localized development of fat, which is essential, if the procedure is to develop the breast, for plumpness of a breast lies in the fat contained therein In view of the lack of evidence as to the value of such devices their sale must be placed in the same category as the purveying of inert and useless remedies

ULCERS DUE TO CHROMIC ACID

To the Editor—I am called on to treat ulcers which originate in the men employed in producing dry colors in a nearby dye industry The ulcers are caused by chromic acid or chromium and its salts We shall be grateful if you can assist us SUBSCRIBER

ANSWER.—Lesions of the skin due to chromium are well recognized industrial dermatoses The following brief account of them is taken almost verbatim from Dr Prosser White's work, Industrial Dermatoses

All workers in free chromic acid and the chromates suffer after a time, unless the precautionary regulations are strictly enforced The chronic chrome dermatoses are (1) the subcuticular vesicle, (2) the sore, or hole, traumatic or follicular, (3) the granuloma and (4) the scar Chrome sores are usually situated at the roots of the nails the creases of the knuckles, and the hairy parts of the backs of the hands and forearms The skin between the fingers shows large numbers of skin-colored painless, subepidermic, pinhead elevations The web between the thumb and first finger is particularly susceptible to ulceration if any crack is present Previous laceration of the cuticle or the mouth of the follicles, however, always determines the site of the ulcer, which may be found on the wrist or arm the penis or the groin

A chrome hole always starts and takes its size and shape from the chip crack or opening in the skin in which it begins If the epidermis has been stripped, the sore retains the shape of the original wound (linear oblong etc) but as the hole deepens, the edges and angles become thickened and rounded If, on the other hand it begins from a follicle or a broken papule, it will most likely remain circular The sore gradually deepens, widens and soon extends to the derma Deep penetration with great thickening of the edge and less surrounding inflammation is characteristic The chrome hole is indolent and conical The size of the chrome hole ordinarily encountered varies from that of a hempseed to that of a bean When neglected, they become complicated by severe pyogenic infection, and large sloughs have been recorded Men can work in very weak solutions of chrome without showing any ill effects

The duration of a chrome sore, if not very deep, is about three weeks, provided the sufferer abandons work and is no longer in contact with the material If he should ignore the trouble and continue his duties it will last indefinitely Chrome holes are essentially a chronic condition, their onset being slow and insidious, and recovery equally tardy They always leave scars, which are usually quite distinctive

Another lesion observed in these "hands" is the septic granuloma It is prevalent in many occupations It results from a low and slow form of inflammation or irritation, usually the feeble but repeated activity of infecting organisms In these cases there may be little skin destruction or the wound closes prematurely and the inflammatory exudates are confined or only partially absorbed Edema, small-celled infiltration and debris remain to form a diffuse, nodular half pea sized and shaped projection

The only method of handling these cases successfully is to prevent them and prophylaxis by measures to prevent contact with chromic acid and its salts should be required in works where laborers may be exposed to these salts

Book Notices

LA LITHIASE BILIAIRE Par A Chauffard Second edition Paper Price 20 francs net Pp 247 with illustrations Paris Masson et Cie 1922

In thirteen chapters, which are really in the form of lectures, Chauffard covers fairly well the subject of gallstones —their pathogenesis, symptoms, complications, diagnosis and treatment He emphasizes the role of cholesteremia in their production, laying less stress than many on infection He analyzes minutely the various types of pain caused by the stones dwelling especially on the areas of cutaneous tenderness He devotes an interesting chapter to the elimination of gallstones by way of the intestine He gives detailed advice as to treatment, telling which cases he regards as suited for surgery, which for hydrotherapy and which for the more strictly medicinal management The book is not a complete textbook that one would consult as an encyclopedia of information on all phases of the subject, but it touches on nearly all the essential clinical features of gallstones, is rich in illustrative clinical cases, and is written in a style so lucid as to make the book not only readable but also entertaining

LES BASES ACTUELLES DU PROBLEME DE LA TUBERCULOSE Par Fernand Bezançon, Professeur a la Faculte de Medecine Paper Price 7 francs Pp 200 Paris Gauthier Villars et Cie 1922

This is one of a series of popular science works published under the title, "Science et Civilisation" It successfully presents to the general public the subject of tuberculosis as viewed by the best minds of the medical world Instruction in all phases of the tuberculosis problem is needed in France, in fact, the author, in the preface, gives as the raison d'etre of the treatise the need of acquainting his public with the facts about tuberculosis, the modes of infection, means of transmission, prophylaxis and treatment The book is addressed to physicians, nurses, social workers and laymen in general Attention is called to the seriousness of the problem from a social standpoint, and its importance as a national menace is made clear

INTERNAL SECRETION AND THE DUCTLESS GLANDS By Swale Vincent LL D D Sc M D Professor of Physiology in the University of London Second edition Cloth Price $8 50 net Pp 422 with 104 illustrations New York Longmans, Green & Co 1922

This book is a very helpful contribution to the difficult subject of endocrinology by an active and competent experimental worker in this field In this edition the portions dealing with clinical phases of the subject have been increased considerably, thus making the little volume more useful to medical students and practitioners Many of the illustrations are photographs of patients suffering from diseases of the organs of internal secretions

The chapters on the gonads, the thyroid, the parathyroids, the suprarenals, the pancreas, the hypophysis, and the specific interrelationship of these glands are the most satisfactory In the chapters on the gastric and intestinal mucosa the author seems unfamiliar with the recent American investigations showing that the 'secretin" of Bayliss and Starling and the "gastrin" of Edkins are artefacts or drugs, and not physiologic substances or hormones The author has deliberately left out all references to the original literature, a fact that diminishes the value of the book In the handling of experimental and clinical facts and speculations, the author is usually critical and conservative He says "If I have not been so optimistic and expansive in the treatment of certain topics as other writers on the same subjects, it is because I am convinced that a surer road to sound knowledge lies in the direction of rigid criticism and a reasoned skepticism'

THE PHYSICAL GROWTH OF CHILDREN FROM BIRTH TO MATURITY By Bird T Baldwin Director and Research Professor of Educational Psychology Cloth Price $3 75 Pp 411 with 24 illustrations Iowa City University of Iowa

This is the first of the University of Iowa Studies in Child Welfare, and is issued from the Iowa Child Welfare Research Station Nothing so complete or exhaustive on the subject has appeared in American literature, and it is doubtful whether any such complete report has appeared in a single volume in the literature of any other country The methods of examination are given in detail, and the results are amply illustrated by tables and charts Every phase of physical growth is taken up, even to strength tests of the different portions of the body An appendix gives a large bibliography

A MANUAL OF PHARMACOLOGY By Walter E Dixon M A M D B Sc Sometime Professor of Materia Medica and Pharmacology at King's College Fifth edition Cloth Price $6 net Pp 468 with 92 illustrations New York Longmans Green & Co 1921

This book is adapted primarily to the student in England, it is not suitable for use in America, as the U S Pharmacopeia names and the activities of the Council on Pharmacy and Chemistry are ignored As is common with many textbooks published in Great Britian proprietary names are used frequently to the exclusion of scientific terminology Hexamina (the British Pharmacopeia name for hexamethylenamine, U S P) and the proprietary "Urotropin" are employed interchangeably The unscientific name Antifebrin, long discredited in America is used by Dixon for acetanilid The revision of the book has been extensive, but at times carelessness is evident One notices that credit is not given others for research or statements, nor are references furnished It is the purpose of the author that the therapeutics in the manual shall serve only to illustrate the pharmacology, he has carefully refrained from creating a treatise on therapeutics or materia medica The material is presented in the commendable form of group treatment The work also includes the drugs brought out during the war, but is not as critical in their evaluations as it might be Tracings, chemical formulas and diagrams abound The subject-matter is presented in a direct, pleasing style, and the book work is excellent

TUBERCULOSIS IN INFANCY AND CHILDHOOD Lectures Delivered at the Children's Hospital Philadelphia under the Auspices of the Philadelphia Pediatric Society By J Claxton Gittings M D Professor of Pediatrics in the Graduate School of Medicine University of Pennsylvania Frank Crozer Knowles M D Professor of Dermatology in the Jefferson Medical College and Astley P C Ashhurst M D Associate Professor in Surgery School of Medicine University of Pennsylvania Cloth Price $5 Pp 273 with 22 illustrations Philadelphia J B Lippincott Company 1922

This work discusses the subject completely from all clinical standpoints, and contains much valuable practical information One of the striking features is a complete chapter on skin manifestations of tuberculosis, a greatly desired and needed contribution and one which comes rather as a surprise to the ordinary reader One could wish that many more illustrations had been added to the medical and dermatologic sections The detail of physical examination and findings in the discussion of the pulmonary involvements is especially exhaustive, as one would expect who has knowledge of the previous work of one of the authors

"Try for Links"—H Le Chatelier the professor of chemistry at the Sorbonne Paris, was recently presented with a gold medal on the completion of his fifty years of teaching and of service to France In his words of acknowledgment he addressed the young chemists present saying, "Try for links, only links Do not try to forge a whole cable at once Discoveries are made as one can, not as one wants to make them The fall of the Titans trying to scale Olympus is being constantly repeated as witness the last years of Sir William Ramsay and Schutzemberg for instance'

Medicolegal

Improper Evidence as to Agency of Nurse in Hospital

(Deming Ladies Hospital Association Price (U S) 276 Fed R 668)

The United States Circuit Court of Appeals, Eighth Circuit, in reversing a judgment for damages obtained by the plaintiff, Mrs Price, on account of her having been burned by metal hot water vessels while she was unconscious after an appendectomy, says that the case went to the jury on the issue of whether a nurse named Miss Schilling, alleged to have been negligent in the matter, was an agent or employee of the hospital That agency was sought to be established by what Miss Schilling herself had said and done The husband of the plaintiff was permitted to answer certain questions with reference to what Miss Schilling did in connection with the operation on his wife, and the facts that she was in attendance during the operation in the operating room and attended Mrs Price in her own room after the operation Mr Price then testified that neither he nor Mrs Price ever employed Miss Schilling as a nurse, and that he did not receive a bill from her for services He said that he saw her working in the operating room, suggested to her that she seemed to be pretty busy, and received the reply Yes, I am on general, and it keeps me busy' He was then asked Did you learn afterward from observation and experience, what 'on general' in a hospital meant? What does it mean?' The objections to this question should have been sustained The agency of Miss Schilling was not apparent, and it not only was not admitted, but was also denied Her statement was not shown to have been ratified Moreover, the testimony introduced, even if it had been admissible, would not have been sufficient to warrant the inference on the part of the jury that Miss Schilling was an agent or employee of the hospital The court thinks too that, in any view of the case, the jury should have been given the requested instruction that the agency of Miss Schilling could not be determined by her statements and her conduct There was also error, the court holds, in a refusal to give a requested instruction that the hospital was not liable because it was a charitable institution

Immaterial Irregularities in Procedure of Board Not Reviewable

(Minaker v Adams et al (Calif) 203 Pac R 806)

The District Court of Appeals of California, First District, Division 2, says that this was an appeal from a judgment of the superior court dismissing a writ of review and affirming all the proceedings of the board of medical examiners in revoking the appellant's license to practice medicine and surgery in the state The action of the board was taken after a hearing, duly and regularly had, on a complaint charging the appellant with having been guilty of unprofessional conduct in procuring a criminal abortion The appellant's contention was that, at the hearing, the board received considerable hearsay testimony and other evidence not admissible Reliance was placed on the case of *Thrasher* v *Board of Medical Examiners* 185 Pac 1006, because of its holding that hearsay evidence is inadmissible in a proceeding such as this one However, the only function of the writ of review in this case was to determine whether the board exceeded its jurisdiction, and the sole question reviewable by the superior court on the proceedings before it and by this court on this appeal was whether the board exceeded its jurisdiction in making the order complained of Conceding the fullest possible force and effect to the language of the Thrasher decision, and the consequent inadmissibility of some of the evidence received by the board in the instant case on the question of the pregnancy of the alleged pregnant woman at the time of her treatment by the appellant, there was, nevertheless, abundant proper evidence in the record that this condition existed This was to be found in the testimony in the coroner's office of the surgeon who performed the necropsy, and in the testimony of a physician who examined the woman when she was taken to a hospital This testimony eliminated any question that might arise, were there an entire absence of legal evidence in the record, as in the Thrasher case, and it conclusively established the jurisdiction of the board to make the order complained of Under such circumstances, any irregularity in the method of procedure in the matter of the admissibility of improper evidence will not be reviewed on a writ of review Wherefore, the judgment appealed from is affirmed

Burden on Plaintiff in Action for Malpractice

(Swat v Foster (Ga) 111 S E R 66)

The Court of Appeals of Georgia, Division 1, says that this was a renewal suit brought within six months of the dismissal of the original suit by the plaintiff's attorney The petition as amended stated among other things that on Sunday evening the petitioner's wife was taken ill The petitioner immediately called at the home of the defendant physician for the purpose of securing his services, but did not see the defendant until Monday morning, when the defendant visited the petitioner's wife, examined her, stated that she was in labor and gave her treatment After about an hour the defendant left, promising to return at 1 p m, but did not do so until about 5 p m, after the petitioner had been to his house at about 4 p m, and urged him to return to look after the patient On that visit he remained about thirty minutes, continued the treatment, and stated that the child would be born in an hour The defendant did not return again, and the petitioner charged that so leaving was an act of gross carelessness and neglect of the patient, who died the next day The petitioner also alleged that his wife was not in labor at all at the time the defendant waited on and treated her, but that her illness was gastritis What was designated as Paragraph 11 of the petition read "Petitioner alleges and charges that the death of his wife was due to the unskilful diagnosis and treatment by defendant as a medical practitioner and to the gross carelessness and neglect in his treatment and handling of said wife's illness' The defendant interposed a general demurrer to the petition, and a special demurrer to Paragraph 11, asking that said paragraph be stricken out because the allegations thereof were vague and indefinite and were conclusions of the pleader

It is well settled, the court goes on to say, in affirming a judgment for the defendant, that, in a suit for damages alleged to have been caused by the malpractice of a physician, the burden is on the plaintiff to show a want of due care, skill or diligence, and also that the injury resulted from the want of such care, skill or diligence Conceding, but not deciding that the petition in the instant case established a want of due care, skill or diligence on the part of the defendant, it was not shown that this negligence was the cause of the death of the plaintiff's wife, Paragraph 11 of the petition having been properly stricken out on the special demurrer interposed The trial court did not, therefore, err in dismissing the suit on general demurrer

Award to Physician for Sprain Held Excessive

(Lebrecht United Railways Co (Mo), 237 S W R 112)

The Supreme Court of Missouri, Division No 2, in reversing a judgment for $12 500 damages that was rendered in favor of the plaintiff a physician, for a sprain of the sacroiliac joint, says that the sudden starting and the closing of the door of one of the defendant's cars, while he was in the act of boarding it, caused him to fall and suffer the injury in question He was not confined to his bed immediately, but, the pain increasing, he went to a hospital, where he remained ten weeks An extension splint and weights were used to pull his leg and take the pressure away from his hip He used crutches for three months after he left the hospital For a while, he was not able to resume the practice of medicine, with the exception of seeing a few patients at his house

It was more than four months after the accident before he went to the office Prior to the accident, he had earned $6,000 or $7,000 a year He was unable to state what his earnings had been subsequent to his injury without referring to his books, but was permitted to approximate his earnings by stating that, until four or five months before the trial, which occurred about two years after his injury, his income had been about 50 per cent of what it was prior to the accident His physician's fee was $150, and his hospital bill a like amount He was 61 years of age The physician who attended him at the hospital said the condition caused intense pain, that one so affected is troubled a long time with it, but he could not state definitely that the injury was permanent In practicing his profession, the plaintiff would not be able to make visits as easily as before A physician who testified for the defendant stated that he made an examination of the plaintiff about nine months after the accident, and found nothing objectively wrong with him, but, on manipulation of the parts on the left side in the region of the back and of the pelvis, he complained of pain This instruction was given the jury

If the jury find for the plaintiff they should assess his damages at such sum as they may believe from the evidence will be fair compensation to him first for any pain of body or mind which the jury may believe from the evidence he has suffered or will hereafter suffer by reason of his injuries and directly caused thereby including permanent injury (if any) second for any loss of earnings in his profession which the jury may believe from the evidence he has sustained or will hereafter sustain by reason of his injuries and directly caused thereby and third for any expense necessarily incurred for medical attention, not exceeding the sum of $150 for hospital bills and $150 for medical care which the jury may believe from the evidence the plaintiff has incurred by reason of his injuries and directly caused thereby You will render a verdict if you find for the plaintiff in an aggregate sum

This instruction the court holds, was not subject to objection, if based on proof sustaining same, but in the instant case it was unauthorized in the absence of such proof, the testimony not being sufficient to sustain an instruction in regard to damages based on proof of permanent injury As has been said, in effect, in numerous cases consequences which are contingent, speculative, or merely possible are not to be considered To justify a recovery for apprehended future consequences, there must be such a degree of probability of their occurring as amounts to a reasonable certainty that they will result from the original injury To say of a thing that it is permanent means that it will continue regardless of a contingency or fortuitous circumstance Furthermore, under the evidence the assessment of damages was excessive, and, without additional evidence, it would authorize the reversal and remanding of this case On this account therefore, and because the trial court in the instruction on the measure of damages authorized the jury to take into consideration the permanency of the plaintiff's injury in the absence of evidence to sustain the same, the cause was reversed and remanded

Power to Defer Judgment Revoking License

(Shoults v Alderson et al (Calif) 203 Pac R 809)

The District Court of Appeal of California, First District, Division 2, says that the appellant, who had been licensed to practice as a "doctor of naturopathy," was, in May, 1918, served with complaint and citation under the provisions of the medical practice act The complaint charged that he had been guilty of unprofessional conduct under said act in affixing to his name certain letters indicating that he was entitled to practice the system or mode of treating the sick or afflicted for which he was not licensed The citation required him to appear before the board for a hearing, June 25 He filed an answer in which he admitted having used the abbreviations 'M D" after his name on his professional cards and stationery and on a sign in front of his office, but alleged that he did so because he had received the degree from a legally chartered medical college of the state of Illinois and he believed he had a right to use this degree after his name, that he had never practiced or held himself out as practicing any art of healing other than "naturopathy" At the hearing he appeared by counsel and in person and admitted the use of the suffix complained of, whereupon he was found guilty of unprofessional conduct as charged in the complaint His attorney stated that he was willing to discontinue the use of the suffix to his name and asked that the board consider that fact and dismiss the proceedings The matter was then discussed and the suggestion was made that judgment be deferred, or that he be put on probation for thirteen months The motion was that he be put on probation for thirteen months When later it was brought to the attention of the board that he had violated his promise and was using the suffix "M D" on his stationery prescriptions and labels for bottles, the secretary of the board wrote to him stating that further hearing in the matter of the revocation of his license would be placed on the calendar for June 24, 1919 On that date, he appeared before the board in person and represented by an attorney and he admitted that he had used stationery on which was printed his name with the suffix M D" Testimony was also given by another witness of further violations by the appellant, in this particular, of the medical practice act On such a showing, the board voted unanimously to revoke his license In inflicting this penalty, the board was merely pronouncing the deferred judgment which it was empowered to render at the first hearing, and this court finds no grounds for the reversal of the judgment of the lower court, which affirmed the proceedings of the respondents acting as the board of medical examiners The board acquired jurisdiction of the appellant and of the subject-matter by the procedure prescribed in the medical practice act and it had power to continue its hearing and finally to inflict the penalty

The appellant contended that because the chairman in stating the motion, did so inaccurately, his language was to be looked to for the sense of the motion carried by the board and that the motion carried by the board was a judgment placing the appellant on probation for thirteen months, which would be a penalty unauthorized by the medical practice act But the court thinks that the power of the board to inflict such a penalty on one found guilty of unprofessional conduct was not a question presented on this appeal that the motion carried by the board was that judgment be deferred for thirteen months, which was the motion seconded, and heard by all members of the board who were present, it being plain from the entire discussion that such was the motion intended to be carried and that was carried This motion was not a final order or judgment, it was merely an order deferring the final judgment for a specified time Assuredly under the general powers given to the board by the medical practice act it would have implied power to continue its hearings from day to day or for any longer period which seemed to it convenient or desirable under the circumstances Such power would be indispensable to the successful functioning of the board in the method provided in the act and would consequently be implied, if not expressed therein Furthermore, the appellant expressly consented to such continuance

A hearing was denied by the Supreme Court of California

Ovarian Function—Graves sums up his paper by stating that ovarian therapy is valuable in treating the hot flushes of the artificial and natural menopause It has an uncertain but nevertheless unequivocal effect on certain dysmenorrheas The same may be said of its influence in cases of amenorrhea, delayed menses, clotting menstrual headaches etc An increasing number of cases seem to prove that it may stimulate fertility Even at its best the action of ovarian extract is uncertain and excepting in occasional brilliant instances rather feeble Outside its specific relationship to the reproductive functions, the influence of ovarian substance on the rest of the bodily organism is slight

Prevention of Premature Births—In order to prevent premature births, Bailey says, the care of the prospective mother must include a reduction of her manual work during the last month of pregnancy and the insistence on a dietary regimen composed largely of carbohydrates The high death rate in the neonatal period must be looked on as preventable to a certain extent and provision of the energy requirement of the new-born is the first step in that direction Bailey suggests that in maternity hospitals the new born be turned over to the pediatrician Obstetricians have been carrying this appalling death rate in the neonatal period with little concerted effort toward its reduction, because it is relinquished to men better trained in pediatrics

Teratoma of Ovary—Several points of interest are stressed by Porter in his recital of a case First, the enormous size of the ovarian cysts without the patient's knowledge or suspicion that anything serious was wrong with her Second complete functioning of the ovaries, including pregnancy occurring in the presence of bilateral ovarian teratomas, child carried beyond term, born naturally but dead Third development of a paratyphoid infection during the puerperium

Absence of Uterus and Vagina—Reel's patient was a young woman presenting in every respect typical feminine characteristics in external physical development while the internal genital tract revealed an absence of one tube, the uterus and the vagina That rudimentary structures found on the right side at times endeavored to undergo some menstrual change seems logical since she has been entirely free from attacks of periodic pain in this region since their removal by operation

Keeping Fallopian Tubes Open—Kennedy uses Cargile membrane hardened in alcohol for at least forty-eight hours, threading it through the fallopian tubes and the cavity of the uterus to keep these tubes open both into the uterine cavity and into the peritoneal cavity The membrane is flexible and strong, nonirritating to the contact tissues and is slowly absorbed giving all raw surfaces time to heal and allowing this part of the genital tract to remain patent He urges greater use of this membrane

Device for Aseptic Intra-Uterine Manipulations—Hendrickson has developed an apparatus and a method which he believes makes possible an almost perfect asepsis in performing any of the ordinary obstetrical manipulations except the cutting operations There need be no fear of infecting a parturient woman such as by a manual removal of adherent placenta even though the woman should have a suppurating bartholinitis

Treatment of Cardiac Failure During Pregnancy—The important feature of a patient with heart disease during pregnancy Pardee says, is the degree of cardiac failure If this is slight the disease is of little importance Even with a moderate degree of failure it will be possible for the child to be born if the mother is allowed to take a risk which is not so great as sometimes stated The first attack of severe decompensation can usually be recovered from with proper treatment unless the attack should occur during labor With proper observation and prompt operation severe decompensation should not occur during labor Abdominal section is the operation of choice in the emergency provided a low forceps cannot be done Ether anesthesia started by chloroform is a better anesthetic for these patients than gas-oxygen Oxygen inhalations from a mask are helpful to clear up a persistent cyanosis Without severe cardiac failure or after recovery from it most patients can be carried through to term or to an induced labor during the eighth month During labor, one should watch for a pulse over 95 or respiration of more than 25 per minute precordial discomfort, dyspnea, cough and not let these little signs become big before putting an end to the labor In treating lesser grades of failure during pregnancy the patient must rest enough to spare the heart from overstrain but this may not necessitate rest in bed for more than a short time Digitalis should be given in doses sufficient to insure an effect With this treatment Pardee feels sure it will be possible to diminish the present mortality of about 25 per cent for severe cases and 10 per cent for all cases to a figure which is less disquieting

New Hydrostatic Bag for Induction of Labor—Lee claims that his bag combines the two desirable features of the Barnes and the Champetier de Ribes and Voorhees bags, i e dilating the cervical canal and supplying an efficient foreign body within the lower zone of the uterus to excite uterine contraction

Retained Extra-Uterine Pregnancy—Riley's patient had the usual signs of pregnancy and felt the fetal movements These without the usual evidence that accompanies tubal rupture suddenly ceased between seven and one-half and eight months of the pregnancy Outside of the presence of an abdominal tumor she enjoyed good health and one year subsequently, gave birth to a full term living child Her pregnancy and labor were normal in every way She subsequently gave birth to four children, two of whom were born dead There was no history of any abnormality during these pregnancies or labors On admission to the hospital, she complained of frequent urination and the presence of an abdominal tumor the size of a croquet ball firmly attached to the left of the uterus causing considerable pain on examination It was fixed and immovable It was rather irregular and hard like a myoma No crepitus was elicited Rectal examination was very painful and the mass felt irregular to the examining finger At the operation the mass was found to be in the left broad ligament On cutting into the mass it proved to be a cavity from which a very foul odor emanated The sac contained the bones of the fetus and a large amount of foul smelling milky colored fluid The bones of the fetus were entirely clean of all tissue It measured 17 inches in height and apparently represents the size of a fetus at seven and one-half or eight months' pregnancy

Innervation of Cardia—A method is described by Carlson et al permitting continuous recording of the tonus and contractions of the cardia in acute experiments and in animals provided with a permanent gastrostomy and esophageal fistula

Blood Anticoagulant in Body Tissues—Whereas normal lung tissue yields a globulin which is a very active blood coagulant, lung tissue dried at room temperature and thoroughly extracted with benzene at this same temperature yields a globulin possessing a very strong anticoagulant action This anticoagulant globulin appears to contain no phosphorus in its protein molecule The globulin fraction from various tissues was found by Mills et al to be capable of yielding this anticoagulant protein, there being no apparent specificity even for widely divergent species The strongest anticoagulant for any blood was obtained from turtle liver The anticoagulant action of the globulin is readily destroyed and an active coagulant formed by the proper addition of cephalin The conclusion is justified that this protein owes its anticoagulative action to its high cephalin combining power

Origin of Cardiac Impulse—The experiments reported by Eyster and Meek comprise a study of the changes in cardiac rhythm for periods of days or weeks following ligation or excision of the sino-auricular node in dogs Disturbance of the normal rhythm, as manifested by a reduction in cardiac rate, a reduction in the As-Vs interval and frequently other changes, invariably results The facts obtained tend to substantiate the paramount importance of the sino-auricular node as the seat of origin of the cardiac impulse in the normal animal They further indicate the ability of this structure to function, even though subject to considerable injury and partial isolation, if sufficient time for recovery is allowed A study of the cardiac acceleration preceded by muscular exercise and by vagus paralysis under atropin administration, before and after excision of the sino-auricular node lends further evidence to the view that it is on this structure that the vagus produces normally its greatest chronotropic influence and through which the normal acceleration in muscular exercise is in large part brought about

Sinoventricular Conduction—New experimental evidence is presented by Eyster and Meek which they believe tends to substantiate the view previously stated, that conduction of the excitation from its origin in the sino-auricular node to the right atrium and auriculoventricular node respectively, occurs normally by separate paths This evidence is the occurrence of auriculoventricular dissociation in dogs after partial isolation of the sino-auricular node

Epithelioma of Cornea—The Keiths believe that the application of radium to tumors of the cornea or the bulbar conjunctiva far excels operative procedure In their case they used 42 mg hours to each half of the eye There have been no ill effects

Pathology of Pyelitis of Pregnancy—The true pathology of the condition is graphically demonstrated by the pyelograms made by Hodges, and consists mainly of dilatation of the renal pelvis and dilatation and kinking of the ureter The dilatation varies greatly The lesser and medium grades will entirely recover, but the more severe grades with atony of the pelvic musculature only partially recover The colon bacillus is usually the infecting organism, but others may occasionally be primary or engrafted on the colon infection The early diagnosis and treatment of pyelitis of pregnancy may be the means of avoiding serious, if not irreparable damage to the kidney Pelvic drainage and lavage is of marked value adding little, if any, risk when properly done

Cause of Vomiting After Gastro-Enterostomy—Vomiting continuing for weeks after a gastro-enterostomy, Pirie states, is usually due to retention of food in the stomach The gastric delay is due to the stoma being placed too far from the pyloric end Roentgen-ray examination not only may disclose the cause, but provide the remedy The first case of vomiting after every meal for three months following gastro-enterostomy was cured by lying on left side after meals Second similar case was cured by lying on left side and rolling over a pillow on stomach

Papillary Cystadenoma of Male Breast—David's patient was 82 The tumor in the breast was first noticed fifteen years previously Twelve years ago the tumor and nipple were removed One year later there was a recurrence [illegible]

general health of the patient was good The microscopic diagnosis was recurrent papillary cystadenoma of the ducts of the breast David urges that in such cases the entire breast be removed

New Method of Skin Grafting—The technic of the method employed by Parce consists in the usual preliminary preparation and the use of the same instruments that one would employ if he were doing a simple Thiersch graft plus the addition of sterile dental modeling composition With two basins of sterile water—one hot and one cold—conveniently at hand, the dental composition is first softened in the hot water and then molded over the surface to which the graft is to be applied and finally placed in the cold water to harden A full thickness autoplastic graft through the dermis into the subcutaneous plexus, but devoid of fatty tissue, is removed with a razor in the ordinary manner turned inside out over the impressioned surface of the composition and held under tension against it by means of fine catgut sutures used to approximate the free edges of the graft across the blank surface of the composition It may take several grafts before the surface of the mold is covered in the desired fashion The skin edges about the area to which the graft is to be applied are slightly undercut so that the margins of the composition with the graft overlying them will slip under these edges The graft is now placed in position and adjusted, this adjustment being made more accurate by applying a compress soaked in hot saline to the composition for a moment slightly softening it when firm pressure will permit such readjustment as is necessary in the composition after the skin has been applied over it The skin margins surrounding the area made free by undercutting are now sutured with fine catgut to those portions of the graft in apposition to them which step serves the double purpose of holding the graft in position and at the same time helps to maintain tension on it A copious dressing with a firm bandage is then applied over the whole area and left undisturbed for a period of eight to ten days, when the sutures holding the graft to the mold are cut, the edges of the composition gently lifted so as not to disturb the graft and finally the whole mold is removed, leaving the epidermized surface beneath

Peritonitis Complicating Prostatectomy—Vanden Berg and Butler report a case of prostatectomy complicated by a fatal peritonitis due probably to soiling of the peritoneum following its accidental opening in enlarging the suprapubic wound They failed to find a similar case on record

Blood Pressure in Cerebral Compression—Clinically, blood pressure compensation following increased intracranial pressure Malone states is a valuable criterion of the degree of cerebral compression when the pupils react to light but is of no service when they do not A sluggish or absent reaction of the pupils to light indicates a grave prognosis and no time should be lost in relieving the cerebral compression A good rule is not to decompress a patient if the blood pressure is falling or is below normal This is evidence that the last stage of compression has been reached and that the medullary centers are exhausted and can no longer compensate

Ochronosis—The diagnosis of ochronosis was made by Oppenheimer and Kline in their case (the forty-first on record) because of the bluish discoloration of the cartilages of the ears and skin of the axillae, the pigmentation of the sclerae and the excretion of a dark urine becoming black on standing In addition the patient had a deforming arthritis of the spine and larger joints and a mitral endocarditis complications frequently present in ochronosis Examination of the urine was repeatedly negative for alkapton body The pigment obtained from the urine, from a costal cartilage and that from the prostate of the case gave the reactions for melanin The pigment from these three sources had similar characteristics The chemical findings are in accord with the belief that ochronosis is dependent on a disordered metabolism of phenol derivatives As in the cases previously reported the cartilages (costal, tracheal, bronchial, auricular and xyphoid) and fibrocartilages (intervertebral disks) are deeply pigmented (bluish black) Large stony masses of bluish pigmentation are found in the prostate and prostatic urethra The kidneys show extensive pigmentation The endocardium intima of the aorta and coronary arteries, skin and sclerae are less intensely pigmented The pigment is not deposited in any quantity in intact intima and endocardium but in areas of degeneration in these structures, however macroscopic deposits occur Diffuse ochronotic pigment is present in albuminous masses (renal casts) and concretions (corpora amylacea of prostate) Fine pigment granules are present in the epithelium of proximal convoluted tubules, and coarser granules are present in the cells of the ascending loops of Henle, distal convoluted tubules and the collecting tubules The pigment is predominatingly diffuse in the matrix of the cartilage and fibrocartilage and when associated with albuminous masses and concretions It is predominatingly granular in perichondrium, periosteum, tendons, fascias connective tissue and in certain renal cells It is present in diffuse and granular forms in injured and degenerated areas The histologic picture in the kidney sections suggests excretion of the pigment by the cells of the proximal convoluted tubules The picture likewise suggests a partial reabsorption of the fine pigment by the cells of the loops of Henle distal convoluted tubules and collecting tubules, and a transformation of the pigment into a more granular form

Nature of Capillary Pulse—Boas claims that the so-called "capillary pulse is not a manifestation of a pulsation of the capillaries but is due to an exaggerated pulsation of the arterioles and possibly of the venules of the subpapillary plexus of the skin In view of this fact it would be well to discard the term 'capillary pulsation and to speak of the systolic flushing of the skin

Studies of Glomerulonephritis—Thirty-two cases of acute glomerulonephritis were studied by Bell and Hartzell In many of these cases death was due to extrarenal causes and early glomerular lesions are available for study Degenerative exudative and proliferative types of inflammation occur in the glomeruli Proliferative changes are chiefly responsible for permanent glomerular damage Acute glomerulonephritis is nearly always due to some acute infectious process usually a streptococcal infection The bacteria gain access to the blood and it is probable that the injury is produced by the direct action of their bodies on the glomerular endothelium An occasional case of acute glomerulonephritis passes into the chronic form, but the great majority of chronic cases do not begin as frankly acute nephritis Acute glomerulonephritis is linked with the chronic form by numerous intermediate cases Glomerular lesions in chronic kidneys correspond to healing or healed stages of acute glomerulitis Old epithelial crescents are common, and disintegrating polymorphonuclear leukocytes are frequently found in the closed glomerular capillaries and in the partially atrophied tubules In a few chronic cases acute and subacute glomerular lesions were found, indicating acute exacerbations In chronic glomerulonephritis many glomeruli are obliterated completely and those persisting show permanent closure of a part of the capillary network Function is carried on by damaged glomeruli, and is depressed not only because of reduction in the total number but also because of the reduced capillary network in those that persist The progressive nature of chronic glomerulonephritis is apparently due in part to repeated acute exacerbations All forms

of glomerulonephritis are due directly to bacterial invasion of the glomeruli, and the various clinical and pathologic types depend on the degree and extent of the permanent glomerular injury

Methyl Alcohol Poisoning—In a fatal case of methyl (wood) alcohol poisoning studied by Rabinovitch changes had occurred in the renal and other functions as evidenced by variations from the normal chemical composition of the blood These, in themselves, disregarding other well known factors, may account for the actual cause of death Methemoglobin played no important part in the production of the cyanosis noted Methyl alcohol could be detected in the tissues examined six days after the ingestion of the drug

Reversed Rhythm of Heart—Kahn emphasizes the distinction that should be made between the terms "reversed mechanism and reversed rhythm" of the heart The "term reversed mechanism" should be confined to express a reversal of the mechanism of impulse formation and conduction The term "reversed rhythm," on the other hand, does not attempt to interpret the direction of stimulus conduction It expresses only a time relationship between the ventricular and auricular contractions, i e, the ventricular beat immediately precedes the auricular beat This includes not only the cases of reversed mechanism, but also those cases in which the mechanism is normal, yet in which the ventricular contraction is delayed and, therefore, is grouped together with the following auricular contraction In these cases, the auriculoventricular node discharges its impulse, in point of time, ahead of the sinus node, yet without reversal of the mechanism

Roentgen-Ray and Blood Pressure Studies of Heart Action—Roentgen-ray examinations and blood pressure studies were made by Levine and Golden on eleven patients with paroxysmal rapid heart action Five had paroxysmal auricular tachycardia, three had paroxysmal ventricular tachycardia, one had paroxysmal auricular flutter and two had paroxysmal auricular fibrillation Observations were made during the attacks and while the heart was beating normally It was found that in eight cases no appreciable dilatation of the heart occurred, in two it was definite but slight and in one it was considerable These results indicated that in ten out of eleven cases it would have been impossible to detect with any certainty by percussion and palpation a change in the size of the heart In seven of the cases blood pressure readings showed that the systolic pressure was apt to fall and the diastolic pressure to rise, resulting in a low pulse pressure which in rare instances became very small, i e, 8 mm This low pulse pressure may explain some of the symptoms that occur during the severe attacks It is suggested that the amount of dilatation and the decrease in pulse pressure are dependent on three factors, the duration of the attack, the rapidity of the ventricles during the attack and the state of health of the heart before the attack occurs In several cases a leukocytosis, even as high as 20 000 and a temperature of 100 F developed with the attacks and quickly subsided as the heart returned to normal

Evolution in Light of Hormone Theory—Keith states that a study of the growth disorders reveals the fact that the hormone systems, centered in the pituitary and suprarenals, are organized on a functional basis Hormone systems represent automatic growth mechanism which, like all living qualities, are hereditary and variable Hormones represent the elements of an automatic system for the control of growth For this reason new characters do not appear at the end of a developmental stage but early in the growth of the fetus New characters appear first in utero, later they become fixed as a new character in the adult stage

Relation of Nutrition to Tooth Development—A study of the gross maxillary and dental defects in 220 rats on defective and deficient diets was made by E V McCollum et al It is shown that the internal structure of the skeleton of the rat can be changed at will by varying the ration which the animals received Some of the faulty diets studied produced rickets often of an exaggerated type, others caused osteoporosis Still others resulted in the development of the peculiar lesion, which has been called osteosclerosis A study of the effects of these diets on the skeleton would indicate that the growth of the skeleton was dependent on at least three substances (1) an organic substance present in certain fats which is not identical with the antixerophthalmic fat soluble A, (2) calcium and (3) phosphorus The studies of diets which contain varying percentages of calcium and calcium phosphate show that the absolute amount of either ion in the diet is of relatively little importance as compared to the ratio which exists between the two That is, normally calcified bone is produced without regard to the reduction or diminution of either calcium or phosphate in the food, provided the content of the other ion is proportionately augmented or depressed

Effect of Strontium on Bone Growth—When strontium replaces calcium in an otherwise satisfactory diet (2.2 per cent strontium carbonate) Shipley et al state it stimulates growth and causes the bones to develop the picture of strontium rickets The anatomic lesions described by Lehnerdt as induced by the administration of strontium to dogs, were not due to the strontium alone but to a diet very poor in calcium and high in phosphorus, and deficient in the factors fat soluble A or a second dietary essential which is

associated with certain fats, notably cod liver oil Cod liver oil does not enable the animal to compensate for a faulty diet containing strontium

Carcinoma of Cervix Uteri Cured—The case reported by Martzloff is one of very early carcinoma of the cervix, a discharge having been present only three months Examination revealed nothing grossly abnormal A panhysterectomy was performed in August, 1921, and today the patient feels perfectly well The patient was 55 years of age Her menopause occured five years ago

Vitamin Promotes Calcium Deposition—Oxidizing cod liver oil for from twelve to twenty hours at 100 C by blowing air through it was just as effective in curing rickets in rats as untreated oil The antirachitic effect of cod liver oil is not due, therefore, to its content of fat soluble A, but to some other factor which the oil contains The existence of this substance which exerts its effects in so remarkable a manner on the growing bones, is now as firmly established as is the existence of any of the three hitherto recognized vitamins From its mode of action, and the very small amounts of it which are required to exert its directive influence on metabolism it must E V McCollum et al believe, be classed with this group of essential nutritive principles

Determination of Globulins in Blood Serum—The two methods described by Henley give results in practical agreement with those obtained by the Cullen and Van Slyke method but are, in some respects at least less involved than the Cullen and Van Slyke method Method 1 estimates the globulins by determining the nitrogen of the filtrate and by making the necessary calculations to determine the globulins by difference Method 2 determines globulins by direct weighing

Determination of Uric Acid in Urine—The reagent employed by Benedict and Franke is arsenic phosphoric tungstic acid reagent and is prepared as follows 100 gm of pure sodium tungstate are placed in a liter pyrex flask and dissolved in about 600 c c of water, 50 gm of pure arsenic acid are now added followed by 25 c c. of 85 per cent phosphoric acid and 20 c c of concentrated hydrochloric acid The mixture is boiled for about twenty minutes, cooled, and diluted to 1 liter The reagent appears to keep indefinitely A 5 per cent solution of sodium cyanid, which should be prepared fresh once in about two months, is also used, and a standard solution of uric acid acidified with hydrochloric acid containing 0 2 mg of uric acid in 10 c c

Hydrogen Ion Concentration of Feces—The normal fecal reaction of apparently healthy men on mixed diets, Robinson found lies between p_H 7 0 and 7 5 though temporary variations beyond this range may occur without giving rise to any unusual sensations on the part of the subject The effects of some common laxatives on the fecal reaction were studied The usual result is the production of an acid stool The administration of the alkali magnesium oxid, does not differ from the others in this respect but the fecal material passed after the cessation of the laxative action is unusually alkaline The physiologic factor is the predominant one in influencing fecal reaction no result being noticeable from the introduction of acidophilic bacteria into the intestine The intestine apparently exerts a regulatory influence which prevents the development of acidity by micro-organisms There is evidence that alkalinity in feces is also due to physiologic rather than biologic causes

Focal Embolic Glomerulonephritis—Ten cases of focal embolic glomerulonephritis are analyzed by Warwick In all ten cases the heart was enlarged from 365 gm (in a small female) to 860 gm, with an average of 515 gm The mitral valve was involved alone five times, the mitral and aortic valves together four times, while the aortic valve alone was involved but once The lesion consisted of vegetations which were sometimes accompanied by ulcerations of the valve leaflets In five cases vegetations and ulcerations occurred together, but in the other five cases vegetations occurred alone, thus disproving the older idea that the endocarditis associated with focal embolic glomerulonephritis was usually of the 'ulcerative" type The vegetations varied markedly in appearance and position on the endocardium The majority were fresh and friable while some were more firm and showed beginning calcification in certain areas In some instances the vegetations were very numerous and extended over the auricular wall In other cases, the vegetations were small and discrete and situated on the edges of the leaflets One heart showed only two small vegetations on the mitral value and one large one on the aortic valve In another case, yellowish white vegetations, associated with calcareous nodules, were found on the mitral valve only In five cases in which blood cultures were taken either just before or just after death, *Streptococcus viridans* was present four times and *Streptococcus pyogenes* once In one case *Streptococcus hemolyticus* was obtained from the blood stream, showing that streptococci other than *Streptococcus viridans* may be responsible for focal embolic glomerulonephritis In all the cases of this series in which a history was available, the urine showed albumin, hyaline and granular casts, occasional leukocytes and persistent red blood cells, but in no case was gross blood present—a point of differentiation from cases of acute hemorrhagic nephritis In all ten cases, the spleen was enlarged

Rôle of Hexamethylenamin in Production of Hematuria—Bloedorn and Houghton report five cases of hematuria, which developed among approximately 400 patients with mild influenza who received from 30 to 60 grains of hexamethylenamin a day The hematuria appeared in from one to seven days following the administration of the drug In an attempt to demonstrate an idiosyncrasy to hexamethylenamin in these patients, the drug was applied in varying dilutions to the slightly abraded skin of the forearm, and in each case a reaction consisting of redness, induration and the production of a raised area, was noted

Method for Counting Cells in Cerebrospinal Fluid—Carter uses the Levy counting chamber with double Neubauer ruling, this being the one in almost universal use for blood counting and Levinson's diluting fluid (methyl violet, 0 2 gm , glacial acetic acid, 5 c c and water to make 100 c c) With a pipet (1 c c) equal parts of cerebrospinal fluid and diluting fluid (0 5 c c of each) are mixed The total number of cells counted multiplied by two gives the total cells per cubic millimeter

*Improved Method for Using Phenoltetrachlorphthalein as Liver Function Test S M Rosenthal Baltimore —p 385

Hemolytic Properties of Arsphenamin—By means of a method described by Grabfield, the hemolytic activity of various samples of arsphenamin was found to vary in a general way as did the toxicity, when the latter depended on variations in the conditions of reduction of the nitro group to the amino group in the preparation of the sample On standing or after shaking in alkaline solution, the hemolytic properties of a given sample decrease, often disappearing altogether "Arsenoxid" is nonhemolytic The sodium salts of various substituted phenylarsonic acids related to arsphenamin are nonhemolytic Warming a sample of disodium arsphenamin to 55 C decreases its hemolytic power Warming the hydrochlorid causes comparatively little diminution of hemolytic power when tested after being changed to the disodium salt The hemolytic power of dihydroxyarsenobenzene (in 1 per cent solution as sodium salt) is nil, but the introduction of amino groups causes the resulting compounds to acquire hemolytic properties in direct proportion to the number of amino groups introduced The antihemolytic action of arsphenamin is similar to that described for sodium arsenate and arsenite when tested against chemical hemolytic agents, none of these substances exert an antihemolytic action against rabbit hemolysin The presence of serum inhibits hemolysis by arsphenamin

Liver Function Test—Phenoltetrachlorphthalein has been injected intravenously by Rosenthal and its subsequent concentration in the blood has been studied In normal dogs there is an immediate rise to approximately 10 per cent., rapidly falling to only a trace or to complete disappearance within fifteen minutes When the liver is damaged the amount of dye in the blood reaches from 15 to 30 or more per cent, and remains elevated for a prolonged period, 11 per cent having been recovered almost two hours after injection There is evidence that the curves obtained have parallel the degree of impairment of liver function and it is believed that the method can be applied clinically as a quantitative test for liver function

Case of Megacolon with Symptoms of Obstruction—Fischel reports the case of a man aged 48, who presented symptoms which led to the diagnosis of acute bowel obstruction due probably to a malignant tumor of the sigmoid At the operation the suture colon from the cecum to the rectum was markedly hypertrophied The condition was recognized as a true megacolon A complete resection of the colon was done beginning at the proximal side of the ileocecal valve and terminating at the disal end of the sigmoid The disal end of the severed sigmoid was inverted and an end to side

anastomis of the ileum to the anterior wall of the rectum was performed The postoperative course was stormy in the extreme The patient was discharged seven weeks after the operation with the wound entirely healed He was seen again three years later He worked steadily, had two large soft stools daily There was considerable urgency, however.

Functional Disturbance of Colon Causes Abdominal Pain —Clinical study of cases has convinced Wilson that pain can be caused by the transference to the sensory tracts of the cord of afferent impulses which arise in the sympathetic and which if retained in that system would cause disturbance of the brain of a reflex character and would not cause physical pain It seems probable that when the muscular activity which originates the nervous impulse is decidedly more powerful than impulses due to normal digestive activity, there is considerable probability of this transference taking place, and when, as in cases approaching the severity of ordinary colic the afferent impulse is an extremely powerful one, the transference of the nervous impulse from the sympathetic system to the sensory tracts of the cord almost invariably takes place and a sensation of pain is the result With regard to the localization of the pain it is not, as a rule, felt over the spot where it probably arose but is usually "referred or "segmental" in character The clinical study of a series of cases in which mental depression and neurasthenic symptoms result from functional disturbance of the colon muscles, shows that there are some cases which cannot be explained by the theory of inhibited cerebral vasodilatation When the circulation alone is concerned, the defect can be removed by a more vigorous mental effort, just as is the case with physical lassitude which can be overcome by a more vigorous muscular effort It is not at all unusual, however, to find cases of functional colon disturbance in which the mental depression is so severe as to be wholly beyond the patient's voluntary control, and constitutes an acute mental misery which is comparable in the mental sphere to a severe physical pain in the sphere of sensation The occurrence of such cases compels recognition of the fact that nervous impulses arising in the colon and passing to the brain along sympathetic nerve paths have the power of directly disturbing that portion (or those functions) of the brain on which the sense of well being is dependent, and of giving rise to an acute mental misery which truly represents the physical pain which they would have felt if the afferent impulse causing it had been transferred from the sympathetic to the sensory tracts of the cord The fact that these cases are really due to the functional disturbance in the colon is demonstrable clinically by the fact that they yield to treatment which lessens the amount of postural activity in the colon

Treatment of Pneumonia —The mortality in Owen's series of 225 cases was 14 2 per cent The treatment consisted in the administration of milk, beef tea, albumin water, and plenty of cold water until after the crisis, ammonium carbonate, 5 grams every four hours for adults and 1 gram for an infant of 1 year, and proportionately according to age Morphin for adults and brandy were the only other remedies used

Treatment of Synovitis of Knee Joint —Chronic effusion of the knee joint Atkins asserts is, in 75 per cent of cases, not due to an injured cartilage, but to a strain of some structure around the joint This can be dealt with effectively by reeducation of the vastus internus, plus the production of as large an increase as is possible in the blood supply around the joint This latter is obtained by (1) contrast baths, (2) limited active exercise of all muscles around the joint, and (3) massage If this treatment is instituted in every case of chronic effusion of the knee joint the number of operations for a so-called injured cartilage will diminish, and many men will be able to enjoy various forms of sport which they otherwise would not be able to take part in for fear of 'putting out" a knee again

Chemistry of Toxemia of Pregnancy—A study of the literature has led de Wesselow to the conclusion that the data available for the chemical findings in normal pregnancy are scanty and contradictory Apparently the organism is in a condition of low nitrogenous metabolism, and therefore from the standpoint of urinary nitrogen distribution is in unstable equilibrium From the conditions present in pregnancy, it appears unlikely that an undue strain is being placed on the excretory organs, but rather that the demands made on the excretory functions of the kidney are, as far as concerns nitrogenous waste products, less than in the normal person The corresponding chemical data for toxemic and eclamptic cases are given In four cases of pyelitis complicating pregnancy the blood urea values varied from 14 to 21 mg Evidence of a renal defect was, however, present in all in the form of a definitely lowered response to the urea concentration test the lowest figure noted being 1 3 per cent It would seem that the indications furnished by the urea concentration test are in these cases, of considerably greater value than determinations of the urea and nonprotein nitrogen of the blood Further the repetition of the test, when it has been possible has usually given indications of the progress of the case With few exceptions, defect of the urea excreting power of the kidney appears to be the rule in the toxemias of pregnancy, and since edema is almost invariably present, the nephritis would appear to be of the mixed type, the impairment of the ability to excrete waste nitrogenous products, though definite, as shown by the urea test, is not usually extreme Marked accumulation of the urea and other nonprotein nitrogenous bodies in the blood is infrequent, but from a functional standpoint the lesion does not appear to differ in any way from the mixed type of nephritis, so frequently seen in nonpregnant women No evidence could be obtained by the methods employed of a differentiation into groups, nor from a chemical standpoint were any definite differences detected between those cases complicated by convulsions and those in which no convulsions occurred On the contrary, the cases studied appeared to present a continuous graduation from the mildest type of albuminuria of pregnancy to the most severe No evidence could be obtained of the existence of an hepatic as distinct from a nephritic toxemia of pregnancy De Wesselow believes that chemical examination should be of definite value in averting the risk of permanent damage to the mother, and in indicating the stage at which induction becomes necessary A definitely raised urea content of the blood above 40 mg per hundred c c is proof that the kidney is severely damaged, and is an indication for induction of labor In default of a raised blood urea, the urea concentration test affords valuable evidence of the condition of the renal function, and, when the figure obtained is below 2 per cent, termination of the pregnancy should be considered Repetition of both examinations, after an interval, is invaluable, since a rising blood urea with a falling concentration capacity constitutes an obvious indication of a progressive lesion In cases in which a low diastatic content is present, chronic disease and a less complete recovery are suggested In all cases blood pressure observations afford most valuable assistance in prognosis and treatment

Extragenital Chorionepithelioma in Male—In the case reported by Miller and Browne a testicular growth was excluded with certainty, and the primary tumor was situated behind the liver, arising there in all probability from an errant primitive germ cell The patient was a male, aged 39 With the exception of slight colds he had been well all his life until about six weeks before admission He then began to be troubled intermittently with a pain in the right side, just "at the foot of the ribs" At first slight, the pain had gradually become worse It was only after admission to the infirmary that he noticed any swelling in his abdomen The swelling became rapidly larger after admission Patient stated that never at any time was he jaundiced and he had never suffered from piles or from swelling of the legs or feet The liver rapidly enlarged and became more painful A needle was put into the liver and blood stained fluid drawn off, the syringe being easily filled, and the fluid under a certain degree of pressure Large cells resembling amebae were present A second specimen was obtained in a similar way a few days later, and on this occasion no such cells were found The pain now became so severe and continuous as to require the frequent administration of heroin Slight jaundice made its appearance, the liver became excessively tender, the least touch causing agony On the thirtieth day after admission the patient died, after having been delirious during the previous twenty-four hours At the necropsy the abdominal cavity was found filled with fluid and clotted blood The liver was enormously enlarged, and showed several tumor like masses, visible through the capsule On section very large tumor masses were seen, some of these consisted of large spaces filled with fluid blood Immediately behind the liver was a large mass, apparently enclosed in a fibrous capsule and containing material similar to that found in the liver tumors In addition there were several large glands behind the peritoneum infiltrated with growth which had the same appearance The testicles were carefully examined, but no abnormality was found, either to the naked eye or microscopically The histologic examination which is described in detail, disclosed the fact that this was a typical chorionepithelioma, which evidently originated in an abnormally situated primitive germ cell The latter, without fertilization had undergone development, producing a teratoma containing all three layers of the embryo plus trophoblast The stimulus for division of the primitive germ cell (gamete) probably was found in the abnormal (not ovarian or testicular) tissue by which the gamete was surrounded The authors suggest that the cause of the malignant transformation of the teratomatous formation may be found in the little understood disturbed balance of internal secretions, occurring in adult and especially in middle life

After-Results of Removal of Tubes and Ovaries—Of 231 patients who answered Bride's questionnaire, 186 had both their ovaries and tubes removed Abdominal or vaginal total hysterectomy had been performed in 8 cases, subtotal or supravaginal hysterectomy had been performed in 178 cases, the remaining 45 patients had either one or both uterine appendages left Vaginal hysterectomy with removal of one appendage had been performed in 2 cases Supravaginal hysterectomy with removal of one appendage had been performed in 3 cases Vaginal hysterectomy with both appendages left had been performed in 40 cases These investigations seem to have established the following points in comparing the conservative and radical operations (1) The general health of nearly all the patients after both operations is much better but a larger percentage are better after the radical operation (2) The temperament of the patients is adversely affected in only a small percentage after either operation, but after the conservative procedure this percentage is slightly larger (3) Flushings occur in a large percentage of patients after either operation The percentage is greater, though not much, after the radical operation (4) A very small percentage of patients complain of nervous symptoms after operation, but the percentage is larger after the conservative operation (5) A very small percentage of women after either operation complain of more pain, but after the conservative operation it is more than twice the percentage after the radical operation (6) A larger percentage of women have disturbances of their sexual relations after the radical than after the conservative operation in the proportion of 39 to 26 per cent (7) There is a greater tendency to adiposity when both ovaries are removed In brief then, so far as the majority of the manifestations of the artificial menopause are concerned there is very little to choose between the two types of operation The advantage lies with the radical operation in every way save two The two exceptions are the occurrence of flushes and the sexual disability

Iniencephaly Without Spina Bifida—Besides the deformity indicated in the title there was in this case absence of the

left cupola of the diaphragm in its dorsolateral part the ventrolateral part being represented by a small muscular band attached to the costal margin in front and with a free posterior edge The left hepatic lobe occupied the space to the left of the heart normally occupied by the left lung The liver was of a doubled-up shape from side to side the groove for the ductus venosus being converted into a canal by fusion of hepatic tissue underneath Some small intestine (7 5 cm) was firmly adherent to the cystic duct and had to be removed with the liver The left kidney and suprarenal body were seen extending up the posterior wall of the thorax, the tip of the suprarenal body lying at the level of the seventh rib while above this was the spleen Between these structures and the heart was the left lung, a small fleshy structure 3 cm in vertical measurement attached to the left side of the pericardium The right lung was also small firm and fleshy, but larger than the left being 5 2 cm long The thymus was large and pale and hung down one third of the way in front of the pericardium, while the thyroid was normally situated and presented no naked eye abnormality The stomach consisted of a vertical cul de-sac, the wall of which was pale and showed some sacculation the apertures of entry and exit were both at the upper end only about 1 cm apart while the sac measured vertically 6 cm The organ lay partly behind the heart and partly behind the liver and surrounded by a large and soft pancreas The small intestine 41 0 cm in length, lay partly behind the pericardium and partly arranged in an irregular fashion in the abdomen ending in the left iliac fossa where the appendix was seen the ileocecal junction was represented by an ampulla-like swelling from which the large intestine extended in an irregularly double sigmoid fashion to turn down into the pelvis to join the rectum which opened at the anus The intestinal canal was everywhere patent, but there was no difference in caliber between the small and large intestine the latter showing no attempt at arrangement into ascending transverse and descending colon The kidneys were both lobulated the right one was normally placed Apart from being prolonged the labor which lasted sixty two hours was normal while the fetal heart, beating at 120 per minute was heard in the early part of labor although at birth the fetus was dead

Fulminant Menstrual Peritonitis—Adami reports his findings in a necropsy made on a young girl aged 14 who died suddenly after an illness of very short duration the exact nature of which could not be determined The only pathology present was found in the abdomen The intestines were wetter than usual and diffusely injected and there was a very definite accumulation of fluid in the pelvic cavity where also the intestinal coils and the fallopian tubes were more intensely injected The fluid was not purulent it was translucent, though at the same time definitely turbid The congestion and increased quantity of fluid indicated that here was a peritonitis of an acute type that had not gone on to suppuration All other organs were normal The girl was menstruating at the time of her death The uterus was firm of normal size, its mucosa reddened, and it contained blood stained fluid There was however no appearance not compatible with simple menstruation The fallopian tubes were injected, as already stated and the fimbriae abnormally 'angry' in appearance The ovaries were normal The symptoms had been abdominal Examination of the abdominal fluid gave a pure culture of a streptococcus in long chains The history was that the girl had been menstruating for three days before her death About twelve hours after the completion of an athletic contest the girl woke with acute abdominal discomfort which gave way to intense pain and the development of an intense toxic comatose state Death supervened just about twelve hours after the appearance of the first symptom Adami gives this explanation of the case Whereas between menstrual periods the uterus is sealed by the cervical plug of mucus during menstruation the mouth of the uterus and so the way to the fallopian tubes and peritoneal cavity is open and that by negative abdominal pressure the contents of the vagina may thus under favorable circumstances be sucked into the peritoneal cavity A single brief period of negative pressure might at most draw the vaginal contents into the mouth of the uterus, but a succession of acts leading to alternative positive and negative pressures in the abdominal cavity, acts such as swinging from ring, to ring round the gymnasium, or again acts of prolonged negative pressure such as balancing inverted with feet in the air on the horse or parallel bars, would strongly favor the suction of vaginal contents along the whole length of the female genital canal

Fish Liver Oils and Other Highly Potent Sources of Vitamin A S S Zilva and J C Drummond—p 1243
Case of Acute Primary Phlegmonous Enteritis J B Y Wilson—p 1244

Bacillus Coli Infection of Urine—Hale-White states that sufferers from this condition must stay in bed, plenty of bland drink such as barley water, should be given to wash out the bacilli food should be light and suitable to the degree of the rise of temperature In young children it is particularly important by every possible means to get them to take and absorb nourishment for they waste rapidly in many instances It pain or frequency of micturition lead to bad nights hyoscyamus and, if necessary, sleeping draughts, or even morphin should be given The patients so rarely die, and the disease is so frequently overlooked, that we must conclude that the natural tendency is for these patients to get well Therefore it is difficult to be sure whether any particular treatment is beneficial, but it seems reasonable to try to disinfect the urine But if the disease is primarily a blood infection and the bacilli are excreted by the urine and then set up the urinary symptoms this treatment will not affect such of the symptoms as are due to the blood infection Usually an autogenous colon vaccine is used, it is difficult to prove that it does good but to give it is reasonable Those who have suffered from the disease once are especially liable to do so again such either have a low resistance to the bacilli or in them they are especially virulent

Congenital Syphilitic Osteitis—Congenital syphilitic disease of bone Turnbull asserts, is not a general systemic condition but is due to the local presence of spirochetes The older the child the fewer are the portions of bone affected In the fetus the infection tends to be widespread, but it is not necessarily universal Further, when several bones are affected the lesions are greater and more conspicuous in some bones than in others It is advisable therefore, in each case to examine as many bones as possible The femur, tibia, humerus and ribs are sites of election, the femur and ribs are easy of access and should be examined in all cases

Rheumatic Heart Disease—Raven is convinced that if rheumatic heart disease could be made equally with tuberculosis a notifiable disease many tragedies would be avoided, it would soon be generally recognized that every case in which there has been the slightest sign of damage to the heart requires long recumbency and longer observation, medical officers should be enabled to supervise the conditions under which patients receive their treatment and institutions should be provided for their recovery if as will be the case, as a general rule treatment at home is not giving the heart its best chance lastly careful watch should be kept over all children with damaged hearts, until they reach an age when they may be expected to exercise the necessary self-restraint The hearts which are much in evidence in the examination room exhibiting various combinations of mur-

murs and thrills, are not those which should interest us most The most interesting heart is the one which, known to have once been involved in an acute rheumatic infection, is nevertheless observed to be functionally efficient ten, twenty, forty and sixty years afterward

Failure of Preventive Treatment of Syphilis—The two men of 30 and 38 were given systematic preventive treatment, and this evidently warded off the primary lesion, but the secondary manifestations developed the same as if no treatment had been given, only five or seven weeks later than usual The failure was probably due to the length of the interval before treatment was begun sixteen days and twenty-eight days after infection

Formaldehyd in Serodiagnosis—Bouttiau concludes from 1,500 applications of the Gate and Papacosta test that the reaction is strictly specific for syphilis

*Conservative Hysterectomy P Lecene and Gaudart d'Allaines —p 561
*Radium Treatment of Hemorrhagic Metritis M Letulle —p 579
*Idem H Cesbron —p 594

"Fundic Hysterectomy"—Lecene applies this term to wedge resection of the fundus of the uterus, with the adnexa, leaving only one ovary or part of one His six illustrations show the various steps of the procedure The seventeen patients recently reexamined, out of the total twenty-one thus treated, confirm the excellent outcome Menstruation had continued regularly in 76 per cent of the women although less profuse than before In 18 per cent there was a tendency to hot flashes or to obesity, so the results were only mediocre One woman of 40 has pronounced symptoms of the artificial menopause, in this case retention of the ovary failed to accomplish its purpose The fold of peritoneum between bladder and uterus is drawn up and sutured to the peritoneal fold at the rear of the uterus This pulls the bladder backward, but none of the patients seemed to feel any ill effects from this The details of the twenty-one cases are given

Radium Treatment of Hemorrhagic Hypertrophic Metritis—Letulle reports a case of this kind in which the hemorrhages returned after radium treatment and again after a second application in seven weeks The woman of 45 returned two months later bleeding even more profusely, until hysterectomy put an end to the hemorrhages His photomicrograms show the fibrinoid aspect, etc, of the tissues, the vessels still permeable for blood, without a trace of coagulation

Radium Treatment of Hemorrhagic Metritis—Cesbron gives the bibliography on this subject since 1912, and discusses in particular the indications and technic for radium treatment of hemorrhagic metritis in virgins, in women during the reproductive period, and during the menopause, and the chronic cases He advocates radium treatment of hemorrhagic metritis in virgins only as the last resource, after failure of all other measures, including organotherapy The results have been constantly favorable in his experience with one to three applications, with intervals of a month The menses are arrested for two or three months, and then they return, normal Several girls thus treated have passed through normal pregnancies since Siredey warns, however, that even a single mild radium exposure may entail permanent sterility In chronic metritis and the metritis of the menopause, radium is incontestably the treatment of choice

*Herpes Zoster and Facial Paralysis G Worms and V de Lavergne. —p 481
*Serodiagnosis of Tuberculosis G Ichok —p 485
*Ischemic Retraction of Finger Flexors Soubeyran —p 490

Herpes Zoster and Facial Paralysis—Worms and de Lavergne are inclined to think that in many instances of facial paralysis for which herpes zoster is responsible, this factor is overlooked The herpes zoster infection affecting the geniculate ganglion may induce a number of clinical pictures from the complete geniculate syndrome to almost pure facial paralysis The lumbar puncture fluid generally shows lymphocytosis and high albumin and sugar content in herpes zoster This completed the differential diagnosis in one case

Serodiagnosis of Tuberculosis—Ichok writes from Besredka's laboratory to confirm the reliability of the complement fixation test for tuberculosis when Besredka's egg antigen is used In 900 persons tested the reaction was constantly negative in the nontuberculous In fifty-four children in an institution, a positive reaction was obtained in four and in these four, tuberculous lesions were discovered later Mozer and Fried applied the test in 1,005 cases of surgical tuberculosis, and report that it is as reliable in this class of cases as the Wassermann reaction with syphilitic disease of the bones Other testimony is accumulating on the value of the test The egg antigen is made by adding 1 liter of distilled water to the yolks of twenty eggs (350 c c) The water must have a neutral reaction The emulsion is then clarified with a 1 per cent solution of sodium hydroxid The amount required varies with different eggs, the optimum is reached when the fluid looks transparent in a thin layer, as in a pipet, and opaque in a thick layer The fluid is diluted to 7 liters The yolks are then in a proportion of about 1 20 (350 7,000 = 1 20) This culture medium is then distributed in Roux boxes (50 to 150 c c) and is sterilized at 110 C. for twenty minutes Four day cultures on this medium sterilized and rendered homogeneous by agitation, form the antigen for the seroreaction The mother emulsion retains its properties indefinitely

Resection of Bones of Fore-Arm for Ischemic Retraction of Flexor Muscles—Soubeyan corrected the crippling retraction of the fingers in the boy of 10 by shortening the long bones to correspond He cut out a segment 2 cm long, inside the periosteum, in both radius and ulna but at different levels No attempt was made to suture the bone, the sutured periosteum cuff forming a support The plaster splint held the elbow flexed, the fingers extended, in complete supination It was discarded the twenty-fifth day, and the functional use of the fingers was regained and has been complete during the eight years to date The arm is 1 5 cm shorter than its mate

*Glycemia in Diabetics M and H Labbe and P Nepveux —p 485
Sensory Disturbances with Facial Paralysis J R Pierre —p 488

Glycemia in Diabetics—Labbe and Nepveu give the composite curve from seven healthy persons tested with 45 gm of glucose in 200 c c of water, fasting, with an additional 150 c c of water at half hour intervals The sugar content

of the blood ran up at once, it reached its maximum in thirty minutes on an average, and returned to the preceding figure by the second or third hour The increase ranged from 0 14 to 0 34 gm In twelve diabetics the increase ranged from 0 5 to 2 gm , the maximum was not reached until very much later, up to 180 minutes, and the reaction persisted much longer, up to four and a half to seven hours The simple test reveals latent diabetes, and is a useful guide for treatment It is the only means to determine whether the diabetic has been cured The glycosuria does not necessarily parallel the glycemia The derangement in regulation of the sugar metabolism may be more severe than the glycosuria would indicate The diabetics in this group generally display more or less of a tendency to obesity and Bright's disease

Psammoma of Nasal Sinuses—The tumor was successfully removed from the girl of 16 after its psammoma nature had been recognized as the sphenoid sinus was cleared out The eyeball on that side had been protruding for a few months The total mass of the tumor spread through the frontal ethmoid and sphenoid sinuses, it was about as large as a hen's egg, and grated like sand under the knife Two operations were required before the last trace of the tumor was removed, and with it a fragment of bone lined with the psammoma tissue Several polyps had to be removed from the nose later, and suppuration in the frontal sinus called for thorough evacuation, but no evidence of return of the tumor has been observed during the five years since It was impossible to determine where the tumor had originated There is a possibility that it might have been connected with some intradural process

Congenital Stenosis of the Esophagus—The new-born infant vomited at once almost all it ingested As it grew older the difficulty in swallowing was intermittent The child was taken to different hospitals and treated with various courses of dieting without avail Esophagoscopy finally revealed a valvelike protrusion of normal mucosa 1 or 2 cm above the cardia Frey cut the free edge of this dilated portion, using a small foreign-body forceps He followed this with systematic dilating procedures every two or three days, and in a month the boy was able to eat normally

Diverticulum in Esophagus—Hug reports three cases in men of 63 to 74 and a case in a woman of 43 The diverticulum was discovered in all in a comparatively early stage The clue had been given by the air bubbles in the pyriform sinus He pushed the diverticulum inside the esophagus, thus inverting and invaginating it, which rapidly entailed the shriveling and casting off of the invaginatum No fistula was left in his cases, although in some the diverticulum was of moderate size The patients could begin to eat at once These pulsion diverticula are always above the mouth of the esophagus and are thus in fact in the hypopharynx

Primary Cancer of the Middle Ear—Junod reports that only six cases of this kind have been encountered in over twenty five years at the Basel ear clinic, among 45,000 ear patients

Intranasal Encephalocele—The encephalocele in the boy of 6 seemed to be merely a cyst, but on its recurrence a year later it was recognized as a transsphenoid encephalocele He developed pneumococcus meningitis after a diagnostic excision Although he recovered from this, he succumbed a year later to streptococcus meningitis Nager was able to find only six analogous cases on record, the list includes one man of 60 and a babe of 3 days In the one case of permanent recovery, the pedicle of the encephalocele was reached and ligated by resecting the upper jaw of the man of 29

Cancer of the Thyroid—In Ruppanner's case the cancer in the man of 50 developed in the esophagus after thyroidectomy The goiter had been removed on account of disturbance in breathing The esophagus carcinoma was safely removed in 1915 In January, 1922, he returned with a recurrence in the trachea and this tumor was removed by the natural route There has been no return since this merely palliative operation and the patient is under close supervision

Incipient Mastoiditis with Otitis Media—Schlittler states that mastoiditis was found in all the fatal cases of intracranial complications of otitis media at the Basel ear clinic An early mastoid operation almost invariably wards them off and he describes how to recognize incipient involvement of the mastoid The pains at night in the diseased ear, and the synchronous pulsation are instructive By having the patient move his finger at each pulsation, we can see whether it corresponds to the pulse Beside the tenderness back of the ear, bulging of the posterior wall of the meatus, and swelling and tenderness at the origin of the sternocleidomastoid muscle and in the zygoma region all point to involvement of the mastoid, as also a creamy purulent discharge, keeping up for five or six weeks, and lack of improvement in hearing after two to four weeks But the synchronous pulsation, its arrest, its persistence, its returns, is the most instructive guide for estimation of mastoiditis With secondary otitis media in diabetes, etc, intracranial complications are less common the tendency being rather to regressive necrotic changes

June 1 1922 52, No 22

*The Nervous System in Disease of Organs A Oswald —p 553
Refractometry and Viscosimetry of the Blood Serum Rohrer —p 555
Squill in Therapeutics J Markwalder —p 560
Pharmacology of Squill E Jenny —p 562

The Nervous System in Relation to Disease of Organs—Oswald presents arguments to sustain the assumption that the nervous system affects the vital reactions more than we realize at present The familiar experience that 'the mouth waters' at sight and smell of appetizing food, suggests that something of the same stimulating nature may occur in one or more of the endocrine glands under certain experiences They may water in response, or their normal 'watering" may be stopped by emotional influences A catarrhal gastric or intestinal affection of neurogenous origin a conjunctivitis from mental overwork, a catarrhal endometritis may resist all treatment until the nervous system is rested and soothed, and then the cure is prompt and complete When the autonomic nervous system is sensitized from any reason, it responds more readily to slight stimuli Gastric and duodenal ulcer colitis chilblains and Raynaud's disease have already demonstrated the frequent preponderant share of the nervous system in their development He is inclined to ascribe to the present mode of life an overstimulation of the

nervous system This entails an excessive functioning of the endocrine glands, they produce an excessive amount of hormones, and this brings excessive growth He offers this as the explanation for the unusually large numbers of exceptionally tall young persons that are developing now, shooting up far beyond the average This does not indicate an improvement but rather deterioration of the race

June 8 1922 52, No 23

*The Blood Supply of Functioning Organs A Fleisch —p 581
*Test for Urobilin E Herzfeld —p 585
Subretinal Cysticercus J Strebel —p 586
*Castration in Pulmonary Tuberculosis W Rochedieu —p 588

The Blood Supply of Functioning Organs—Fleisch has devised a method for estimating the blood supply to different organs at work and at rest With this he has determined that the acid products generated by the work of the tissues possess a vessel-dilating action The blood supply is thus increased proportional to the amount of metabolic waste products formed "Every organ, every segment of tissue receives exactly the amount of blood it requires for the work it is doing at the moment" The intensity of the dilatation of the vessels is a direct function of the amount of hydrogen ions

Test for Urobilin—Herzfeld has applied the zinc acetate fluorescence technic as a test for urobilin, and has found it sensitive and reliable In 400 specimens of blood serum examined, there were traces of urobilin only in seven In the twenty-four hours' urine it averaged 50 mg in the healthy and in scarlet fever, 80 in polyarthritis and nephritis, 90 in the pregnant and 250 mg with cirrhosis of the liver

Outcome After Termination of Pregnancy on Account of Pulmonary Tuberculosis—Rochedieu tabulates the condition before, afterward and several years later in 9 cases of pulmonary tuberculosis in which abortion was induced and ovarian functioning arrested by roentgenization, and in 18 cases by abdominal hysterotomy and tubal sterilization The ultimate outcome was much better in the castration group Only 2 of the 9 have died since and all the others are materially improved, while only 5 have improved in the 18 in the other group and 6 have died The roentgen castration arresting ovulation seems to have a very favorable influence on the disease Temporary or definite castration is therefore advisable to supplement the artificial termination of the pregnancy in pulmonary tuberculosis

Archivio Italiano di Chirurgia, Bologna

April 1922 5, No 2

Reaction of Tissues to Sponge and Rubber C Vaccari —p 117
*The Ambard Ureosecretory Constant M Melanotte —p 150
Fracture of the Skull F Magni —p 177
*Delayed Healing of Fractures G Marsiglia —p 197
*Operative Treatment of Femoral Thrombosis M Fasano —p 207
*The Stomach Tube Before Operating for Perforation R Gandusio and G Pototschnig —p 212
*Treatment of Perforation of the Stomach R Gandusio —p 217

Reaction of Tissues to Introduction of Rubber Sponge and Sheet Rubber—Vaccari's research has confirmed that there is no special reaction to rubber introduced into the tissues It behaves like any other aseptic foreign body except that there may be some chemical reaction in time from the substances released as the rubber gradually disintegrates In twenty-two experiments on rabbits and other animals, rubber was used for various purposes including the suspension of the kidneys with a strip of rubber sponge or sheet rubber The rubber became coated with new formed tissue in time This encapsulation of the rubber renders it especially valuable for an isolating medium between tissues In two clinical cases a piece of rubber sponge was used to fill up a cavity in a long bone after an osteomyelitic focus had been scraped out In one of these cases the local tuberculous process flared up anew nearly a year later, it is possible that the presence of the foreign body may have contributed to this

The Ambard Constant—Melanotte warns that fever diabetes, pregnancy, general anesthesia and nephritis with tendency to dropsy may each and all modify conditions so that the Ambard index may prove misleading This is also possible from reflex action with catheterization of the ureters He compares the findings of the Ambard index with the course in 53 cases of prostate enlargement, 13 of calculi or tumors in the bladder, and 142 cases of kidney disease The index is a sentinel that warns when we are approaching the danger zone, but it does not take the place of the catheter for the ureters, these supplement each other, and enable the indications for nephrectomy to be materially extended

Delayed Healing of Fractures—Marsiglia reviews what has been published on the influence of endocrine glands on healing of fractures The experimental research to date has been done almost exclusively on young, still growing animals Thyroidectomy seemed to retard the healing of fractures, and thymectomy not only retarded but seemed to prevent healing Ovariectomy, on the other hand, seemed to hasten the formation of callus Marsiglia has repeated these experiments on adult dogs, and was unable to detect any retarding influence on the normal healing of fractures

Operative Treatment for Femoral Thrombosis—Fasano's patient was a man of 68 who had been having lancinating pains in the left foot for a month and there were signs of beginning gangrene Pulsation was evident below the femoral arch although the pains involved the whole limb The femoral artery was exposed and it was seen that the pulse wave stopped 3 cm below Poupart's ligament The artery was incised for 3 cm, 1 cm below this point This revealed an organized thrombus, compact and adherent to the vessel wall It was forced out completely by manipulations, and the blood spurted at once The artery was sutured The pulse became perceptible in the foot, but this did not last more than a day or two, but the pains subsided and have not returned during the ten months since and the gait is normal The thrombosis evidently extended or reformed below the field of operation but the removal of the accessible thrombus opened the passage into the deep collaterals The circulation in these was enough to insure the nourishment of the tissues and check the tendency to gangrene

The Stomach Tube Before Operating for Perforation of the Stomach—Gandusio and Pototschnig protest against the ban on lavage of the stomach before operating on a perforated gastric ulcer They advocate it as a direct advantage for both the patient and the surgeon The possible theoretical objections to it are disproved by actual experience They do not rinse out the stomach, but merely aspirate the contents

Resection of the Stomach for Perforated Ulcer—Gandusio's practical experience has demonstrated that when the operation can follow within two or three hours of the perforation, and the patients are young and in good condition, we need not hesitate to resect the stomach or duodenum and close the abdomen completely afterwards Three cases are described and the prompt recovery is emphasized The contents were aspirated as a preliminary measure The symptoms of peritonitis subsided so promptly and completely that bowel functioning was resumed in two or three days and the wound healed by primary intention In two of the cases the perforation was the first sign of the stomach affection

Congenital Malformation of Skull and Spine M Bertolotti and G Mattirolo —p 253
The Inventor of the Electric Thermoplore F de Raffaele —p 262

Traumatic Luxation of the Hip-Joint in Children—Roello encountered only three cases of traumatic luxation of the hip joint in children in a total of 1,463 cases of traumatic injury of bones or joints in ten years Two of these cases are illustrated here, and the promptness of the cure is

emphasized after reduction Both boys could use the limb normally five days after removal of the plaster bandage, about sixteen days after the reduction procedures

Tardy Ulnar Paralysis After Fracture—In Lusenti's two cases, the ulnar paralysis developed in a young woman and a man of 45 nineteen and forty years after the head of the humerus had been fractured in childhood with resulting tendency to valgus deformity In two similar cases on record the interval was fifty and fifty-seven years before the paralysis developed Electric treatment and resting the joint cured his first patient as likewise in Panis' case Neurolysis alone has seldom succeeded In Lusenti's second case, he resected the large pseudoneuroma on the nerve, and before suturing, shifted the nerve to a position in front of the humerus where it could be sutured without traction, and was protected against further strain

Growth Exostoses—Sanvenero describes a family in which round bunches developed on the long bones during the period of active growth In the father they were first noticed at the age of 12, and became large enough to show at 18, but did not develop further after 25 The exostoses cast a shadow like normal bones The daughter now 8, presents similar multiple bone growths The tendency to symmetry the large number, and the hereditary character distinguish these growth exostoses from those encountered in various diseases and after trauma In one family the exostoses in a boy of 4 are the miniature reproduction of his father's Marie has published two cases with several hundred exostoses of this kind The limbs may be of uneven length There are rarely any complications otherwise, in Sanvenero's adult case the use of one knee is hampered by the large exostosis in the popliteal space, but there is no nervous or vascular disturbance No medical treatment is of any avail, and if the exostoses are resected during the period of active growth there may be recurrence In Martel's case, the recurrence was in the form of a malignant tumor

Loose Bodies in Joints—Pollidori's review of the literature confirms that the origin of loose bodies in joints is still an unsettled question The knee is usually the joint involved, and in a case described in detail the traumatic origin of the two loose bodies was sustained by the history and by the microscopic findings The loose bodies became incarcerated at times, but aside from these periods the gait was not affected There had been severe trauma of the knee at the age of 8 and again at 10, but the first symptoms developed a year later At the age of 24 a separate incision was made to remove each of the two loose bodies and normal functioning of the joint was restored

Hemophilic Arthritis—Montanari has had 11 cases and knows of 3 more in which, without known cause, or insignificant trauma, the knee, shoulder, elbow or wrist filled with fluid, with ecchymoses in the vicinity Slight fever followed, and the condition was chronic the extravasated blood not being absorbed for months and then only incompletely In some of the cases the absorption was rapid and complete in a few days but a new hematoma soon developed Atrophy of the limb above followed, in one case the middle third of the thigh measured 8 cm less in circumference than its mate The roentgenograms showed nothing pathognomonic In 6 of the families the hereditary transmission of the hemophilia could be traced through generations four in one family This hemophilic arthritis represents an attenuated form of hemophilia, with a tendency to be outgrown in time Inherited syphilis was known in 2 cases, and was suspected in a third No attempt at operative treatment was made, extension was applied to combat contracture and the joint was immobilized in plaster The accumulation of blood can be tapped at need, followed by a compressing bandage and immobilization, and ovarian or thyroid treatment can be tried, or Weil's method of injecting blood serum every two months for years If ankylosis requires operative measures, they should be postponed until the tendency to hemophilia has been outgrown to some extent In 2 of the cases several joints were affected, but in 3 both knees alone, in another case the right knee and right shoulder The first disturbance was usually noted at the age of 5 or 6, and it kept to the same joint In one case recurrence thirty times had been recorded

Chordoma of the Sacrum R Micotti—p 265
Postoperative Acetonuria T Laurenti—p 282
Surgery of the Papilla of Vater O Tenani—p 291 Cont'd

Kinking of Intestine from Membranous Pericolitis—The intestine was bound down by the long pedicle of a fibrous body that had developed during the pericolitis The inflammatory origin was beyond question In this class of cases the membranous pericolitis is liable to return, while with the congenital pericolic membrane, once removed, there is no recurrence It is important therefore to differentiate these two groups and with the inflammatory type take extreme precautions against irritating the tissues in any way, operating rapidly and leaving no raw surfaces and, perhaps, concluding by pouring in a little liquid petrolatum to ward off adhesion between the loops

Chordoma of the Sacrum—Micotti's patient was a man of 53 and he died a few days after removal of the malignant chordoma The first symptoms had been noted about three months before shortly after a trauma of the region, and the tumor rapidly increased in size It is the fourth case on record he says in men and only one case is known in a woman Exploratory puncture in his case differentiated the lesion before the operation Even when safely removed, the growth recurred *in situ* after an interval of four months and thirteen months in two of the cases, but metastasis was never known

Postoperative Acetonuria—Laurenti concludes from study of eighty five men and seventy-five women after various operations that acetonuria is almost constantly observed after chlorotorm and ether anesthesia and after spinal anesthesia, but it is rare with local anesthesia The acetonuria never seemed to have any influence on the postoperative course, and no connection was apparent with the nature of the lesion, the fever or the nature of the operation It disappeared almost constantly as soon as solid food was given after the liquid food of the first three to eight days He ascribes it to the strain of the operation

Porphyrinuria, With and Without Colic—In explanation of the remarkable clinical picture of acute porphyrinuria, that is, severe abdominal colic with porphyrinuria, in which, after several attacks, death ensues amid neuritic manifestations Snapper sets up the hypothesis that in such cases a chronic poisoning damages first the retroperitoneal nerve ganglions and thus brings on colic and porphyrinuria Later, this intoxication affects the whole nervous system, and the patient succumbs under symptoms of polyneuritis Two cases are described, with the necropsy findings, in which there were no colic pains at any time The patients were two men of 21 and 29

Blood Pressure in Heart Disease with Dyspnea—Frehse examined for a period of a year and a half all the cardiac patients entering his clinic, and studied also the case histories of cardiac patients for five years back, with a view to ascertaining the relation to blood pressure of dyspnea in cardiac patients The histories of 700 cardiac patients constitute the basis for his statements There were patients with valvular lesions and muscular insufficiency, all grades of stasis, from the mildest form up to stasis with grave dyspnea cyanosis edema and exudate In the majority of these patients arterial pressure at the height of stasis was normal In 142 patients the maximal pressure was increased to 150 mm of mercury But the significant thing was that out of this large number of cardiac patients not a single case was found in which the high blood pressure seemed to causally connected with the dyspnea

Rectitis and Its Consequences—Smital analyzes the experiences in Hochenegg's service with 80 cases of inflammatory disease of the rectum and its sequels Only 21 were men and 15 were women of the 21 cases in which syphilis was responsible In the 17 gonococcus cases, 12 were women, as also 8 of the 11 tuberculous cases The consecutive strictures almost always required operative measures External rectotomy gave excellent results in the 12 cases followed to date out of the total 22 One of the 5 with extirpation of the rectum is in good health ten years later One woman was kept in good condition for two years by bougie dilatation, but then neglected it and required an operation Conservative measures are applicable only in the initial stage, and on suspicion of syphilis In 5 cases cancer developed later, but only in one instance in the rectum, in this case the carcinoma followed a year after colostomy for gonococcus stenosis of the rectum An endless thread method is illustrated which has proved extremely satisfactory A silk thread is passed from the natural to the artificial anus, and with this thread a long loop of tubing is pulled back and forth through the stricture The man does this himself, and the colostomy was closed except for the thread Defecation has thus been rendered possible by the natural route for sixteen years to date To dilate the stricture more effectually the tubing is reenforced with a smaller tube slipped inside To keep the thread from cutting the loop of tubing, a short segment of narrow tubing is strung on the anal end of the silk thread

Birth Paralysis—Schubert presents evidence that malformations and deformities are so common with birth paralysis that the latter must be regarded as of intra-uterine origin, and not the result of birth trauma as a rule

Transfusion of Blood and Own Blood Transfusion—Goder has compiled 52 cases in which the extravasated blood was infused, with recovery of all but one of the otherwise practically moribund patients He reports a favorable case from his own experience, and commends the procedure as harmless and life-saving Tubal abortion is generally the indication, but it has been applied with rupture of the spleen, of the liver, and with gunshot wound of the spleen and of the lung It is not necessary to defibrinate the blood, it is merely citrated and strained through several layers of mull lining the funnel

Chronic Nonspecific Orchitis and Epididymitis—Mandl assumed a tuberculous origin in three of his cases, and in two a needless semicastration was done In three of the cases a Bassini operation for inguinal hernia was evidently a factor, as the disturbances soon followed Epididymitis erotica may explain one case, and infection from prostatitis another, not of gonococcal origin

Prodromal Eruption in Measles. F J Nothen —p 211

The Heart Sounds in Children—Kaulen discusses the findings with the Bock differential stethoscope in 248 children from 1 month to 14 years old

Dysentery in Children—Piltz contends that dysentery is much more common in infants than generally suspected It is highly contagious, and is often responsible for a part of the hot weather infant mortality The dysentery may run a mild course but may aggravate nutritional disturbance from other causes Complications in the form of pyelocystitis and pyelonephritis are comparatively frequent and of grave prognosis

Influence of Atropin on Renal Elimination of Salt and Water in Children.—Twenty tests were made on eight children, including six infants, all but two of the children had healthy kidneys Small doses of atropin seemed to stimulate the vagus and thus check the elimination of water and chlorids Large doses paralyzed the vagus and the output of water and chlorids increased

Intestinal Neuroses in Infants—Stargardter reports the cases of three breast fed and apparently normal infants who developed diarrhea, flatulence and colic for which no explanation could be found in the food or infection Formed stools appeared after four or five daily intramuscular injections of epinephrin, and the cure was complete by the eighth or tenth day in 2 of the infants, the other child had several relapses Probably intercurrent infections were responsible for this The benefit from epinephrin seems to stamp the dyspepsia in such cases as a sympathicotonic neurosis, if all other causes can be excluded and dietetic measures fail to relieve These children showed no signs that suggested the exudative diathesis, and after recovery did not display any tendency to nervousness

Heat Regulation in Infants—Mader discusses in particular the malfunctioning of the heat regulating apparatus in deformed new-born infants

A Pre-Eruption in Measles—Nothen cites 4 cases in which children convalescing from scarlet fever developed measles, and the actual measles eruption was preceded by a fleeting pre-eruption which came and went repeatedly within a few hours or days, shifting around, and showing all types of exanthemas, including rose spots, urticaria and purpura, as well as scarlatinal and measles eruption types It has little diagnostic value unless possibly giving a clue to measles in an otherwise puzzling case

Recent Literature on Stomach Disease W Wolff —p 702

What the Practitioner Should Know About the Causes and Treatment of Myopia—Elschnig remarks in conclusion that when a hereditary predisposition is suspected, the progress of the myopia can be checked by improving the general health, heeding physical anomalies, and treating inherited syphilis Special care should be taken not to strain the eyes (near work only with good light, not too strong etc), and glasses should be worn for near work Glasses for distance are of far less importance For some years he has ordered instillation of pilocarpin two or three times a week, evenings, and is convinced that this seemed to have a favorable influence on the progress of the myopia Atropin, he says, is useless or harmful

Variations in Vessel Tonus Under Protein Therapy—Glaser's research on the hemoclastic crisis was mentioned recently, June 3, 1922, p 1768 He explains the drop in the number of leukocytes after parenteral injection of a protein as a vagotonic manifestation—the expression of a brief anaphylactoid condition This brief vagotonic phenomenon may persist and become evident as the alimentary test leukopenia or hemoclastic crisis The leukopenia in this latter phase, he argues, is merely the manifestation of altered distribution of the leukocytes, from the change in the tonus of the vegetative nervous system He has witnessed the transformation of a sympathicotonic alimentary leukocytosis into a vagotonic alimentary leukopenia under the influence of parenteral injection of a protein

High Blood Pressure—Kisch has found the average blood pressure in men of 40 or 45 of medium strength and build to be about 140, and 5 or 10 mm mercury higher than this in larger and stronger men, fond of sports In women, up to 130 was the average before the menopause Transient hypertonia is common, and is liable to prove misleading Even in the healthy various factors may modify the pressure With pain from gallstones the pressure may keep high for weeks, and return to normal after removal of the cause of the pains Certain drugs, such as digitalis and pituitary extract send up the pressure In 3 cases of exophthalmic goiter in young women, the pressure was 145 and 150 but dropped by 20 and 30 mm as the hyperthyroidism improved In certain other cases of exophthalmic goiter the blood pressure was below normal This was the rule also in attacks of angina pectoris A single pressure reading is thus liable to be misleading in all patients With arteriosclerosis affecting the aorta in particular, the pressure was very seldom over 160 or 170 and the diastolic pressure was normal or only slightly above With arteriosclerosis of the peripheral vessels both the systolic and the diastolic pressure were higher, up to 180 and 200 was common But the pressure and the pulse alone with arteriosclerosis afford little insight into the severity of the process and the functional capacity of the heart There is also a sympathicotonic form of asthma with remarkably high pressure for which no explanation can be found The blood pressure was found very high also in a few cases of diabetes, a "nervous chromaffine diabetes with high blood pressure"

Carbon Arc Light Treatment of Surgical Tuberculosis—Fried reports from the Lupus Institute at Vienna that severe tuberculous lesions in bones and joints as well as lupus healed under the arc light treatment, alone or supplemented with roentgen ray treatment It was applied on the indications for and principles of heliotherapy In one series of outpatients severe processes in the knee healed without an immobilizing dressing and without appreciable impairment of function Caries of sternum ribs, foot and hand sometimes healed under the arc light alone An 80 amperes lamp was used or three lamps of 20 amperes each The latter allowed a larger number to be treated at a time It was impossible to foretell the cases in which treatment would be successful The organism may lack the reacting power necessary but these refractory cases should not deter from trying the arc light treatment for a few weeks or months in suitable cases No injurious by effects were ever observed, except occasional transient sunburn effects The aim was to tan the whole body the arc light 60 or 80 cm from the body the focus approached to 30 or 35 cm the sittings never over an hour and repeated three times a week The number of cases is not mentioned but this treatment has been regularly applied since 1915

Ether in Whooping Cough—Reim injected daily 1 c c of ether, with 0 05 gm camphor subcutaneously in treatment of infants and twice this amount in older children, in a recent epidemic of thirty-seven cases of whooping cough The course was mitigated materially in three infants less than three months old in the third or fourth week of the disease All bore the injections without apparent harm After five or six injections the paroxysms dropped from 18 or 24 a day to 6 or 8 His experience has convinced him of the value of this ether-camphor treatment especially in the early stages of whooping cough

The Nature of Allergy and Anergy C Kraemer—p 174
Marriage of Consumptives Schaefer—p 180
*Operative Treatment of Pulmonary Tuberculosis H V Wagner—p 181
Analysis of Pulmonary Tuberculosis. E Guth—p 193

Legislation for Prophylaxis of Tuberculosis—Kreuser outlines the regulations which he would like to have adopted to provide for notification, welfare work, ways and means, etc, for a more systematic campaign against tuberculosis

Operative Treatment of Pulmonary Tuberculosis—Wagner comments on the prevailing trend towards operative procedures for pulmonary tuberculosis, and the more and more complete abandoning of surgery for bone and joint tuberculosis In each of these lines brilliant success is being realized If nothing eles is accomplished, the thoracoplasty usually dries up the source for contagion of others in incurable cases With bone and joint tuberculosis, almost as fine results are being realized from heliotherapy in the vicinity of Berlin as Rollier has reported from the Leysin mountain *climate In the Berlin experiences, the action of the sun*light was enhanced by reflection from water, keeping the patients on rafts The heliotherapy was also supplemented with means to induce passive hyperemia in the lesion, usually for four hours three times a day, with an hour's interval Each time, from 0 2 to 1 gm of sodium iodid is given internally before applying the band Bier assumes that the iodin is deposited in the region under passive hyperemia It promotes healing and counteracts the tendency to abscess formation under the heliotherapy No plaster casts are used, but extension is applied, and passive and active exercises, but never to the extent of inducing pain Bier's serial roentgenograms have demonstrated that even large sequesters are resorbed in time, the passive hyperemia seems to be responsible for this The long wave portion of the spectrum seems to be the effectual portion for treatment of tuberculosis In refractory cases, a change of radiant energy, a change of climate, the mountains or the sea may prove successful In conclusion, Wagner remarks that we smile at the nose rings of the African tribes, and the deformed feet of Chinese women, forgetting that we maltreat in the same way one of the most important organs of our body, the skin It is our protection against pathogenic organisms, our most important excreting and temperature regulating organ Our constant covering up of the skin hampers its functioning

*Renal Hematuria A Schuppel—p 201
*Surgery of the Prostate B von Rihmer—p 214
Contrast Medium for Pyelography F *Gastreich—p 227*

Decapsulation of Kidney for Renal Hematuria—The decapsulation failed to arrest the essential hematuria from the left kidney in the man of 55, and the kidney was removed Incipient senile contracted kidney with sclerosis of the arterioles had been responsible for the hematuria Decapsulation is futile in such cases If internal treatment and roentgen-ray exposure of the spleen fail to relieve, nephrectomy should follow at once

Operative Treatment of Hypertrophied Prostate—Rihmer relates that the mortality was 31 per cent in his 121 cases of hypertrophied prostate treated by catheterization alone Aside from 31 with acute prostatic retention—who all recovered—23 died of the 95 being thus treated for chronic partial retention, 8 of the 16 with paradoxic ischuria, and 2 of the 5 with urosepsis The death rate is thus high with catheter treatment alone There were 5 deaths among the 18 uremia cases treated by cystostomy, calculi formed in some of the others, but a number are living in robust health six or seven years later All were cured in the 4 cases of chronic partial retention and in the 8 with total retention, all with some signs of infection In Alapy's series of 14 cases, cystostomy improved conditions so that operative measures became possible, with the recovery of 10 In 6 cases of severe prostatic uremia he operated in two stages, first reducing the uremia by cystostomy before attempting the prostatectomy The effect of cystostomy is prompter and more complete than from a retention catheter The bladder has to be emptied gradually with much distention The scar of the cystostomy may have to be resected later, but, with all its drawbacks, the two-stage Freyer operation saves many men otherwise doomed The indications can be much extended without increasing the mortality In the sclerosis cases—the so-called atrophy of the prostate—intra-urethral measures may be advisable, but recurrence of symptoms is liable

Estimation of Energy Metabolism from the Respiration—Krogh describes a very simple apparatus which records the amount of oxygen consumed, and with as much precision as the gas analysis methods The recording spirometer contains a tank of *natronkalk* to absorb the carbon dioxid as the subject inhales and expels his breath, with a known supply of oxygen from an oxygen tank The diet is carefully regulated and the urine findings recorded He compares the data obtained by this means with Benedict's findings and Boothby and Sandeford's tables of basal metabolic rate determinations Absolute repose and relaxed muscles are imperative, and this renders the research difficult with children it may be necessary to give the child chloral or other sedative before the test can be properly applied

Active Immunization Against Diphtheria—Juul reviews what has been accomplished in Europe and America in this line guided by the Schick reaction, and he urges the adoption in Denmark of Zingher's method

Orthostatic Albuminuria Disappears During Pregnancy—The orthostatic albuminuria had been under supervision since the age of 10 Albumin was never found in the morning urine and no tube casts were ever discovered but albuminuria was found constantly in the afternoon urine except during the months of her three pregnancies at the age of 19, 23 and 27 No albumin was found at any time during gestation The albuminuria returned each time after delivery The absence of albuminuria on one occasion, eight days after the anticipated menstrual period had failed to appear was accepted as a sign of pregnancy, soon confirmed by other signs

Steinach's Rejuvenation Operation—Sand's article is continued, but in this instalment he reports favorable experiences from operative treatment in fifteen cases of premature senility or impotency or depression He thinks Steinach's principle is applied best by epididymectomy, resecting a segment, the farthest from the head of the epididymis, ligating and thermocauterizing the stumps all under local anesthesia, but with extreme care not to injure the delicate nerves and vessels necessary for the testicle

THE NEEDS AND DUTIES OF DERMATOLOGY *

ERNEST DWIGHT CHIPMAN, M D
SAN FRANCISCO

As prelude to a strictly scientific program, it seems fitting that the chairman's address should deal with some of the more general considerations which concern dermatology as a specialty There are many topics deserving of careful thought, but nothing is more timely, perhaps, than a resume of our needs and duties

In a general sense, our greatest need is efficiency, and our paramount duty is service Efficiency and service are closely related, because the greater our efficiency, the greater our capacity for service

The question of efficiency should interest us with respect to both immediate and future requirements It were well that we plan somewhat for the dermatology of tomorrow, even while seeking to better that of today

We must all be aware of the growing sentiment toward standardization in the specialties We have been, and we are now, living in an age of self-styled specialists The specialist is as easily made as home-brew and is of equally harmful potential The only criterion of proficiency is recognition by fellow practitioners of one's own branch Such recognition may take the form of election to a national society This is not necessarily conclusive, for good men are sometimes passed by and indifferent ones chosen Under present conditions, the national societies have an opportunity of rendering infinitely useful service This, I believe, they are for the most part doing, but it is self-evident that, properly to function in this respect, they must resolutely avoid anything which savors of personal animosity, racial antipathy, nepotism or friendly predilection

The fact that specialism is entered so easily and through so many channels does not make for uniformity of standards Whatever may be said against a wider application of the elective system for the undergraduate medical students, it seems obvious that those who intend to specialize should be given the greatest latitude in their intern year

If the well-educated man is one who knows everything about something and something about everything, the well-trained specialist is one who knows everything about his own department and something about all the others So that, however zealously we may strive for perfection in one line, it must not be at the expense of broad general training Specialism of today is justly criticized on the ground of a tendency toward narrowness The reason for this criticism should be absolutely removed

Postgraduate colleges as conducted today undoubtedly perform valuable service The casual course of six weeks does not, however, equip one for a specialty What seems an urgent need is the designation by unquestioned institutions which will give the same standing to the specialist that the M D degree gives the general practitioner

What about our own case? Of course we need more efficiency We are quite conscious of our shortcomings And obviously, by the development of personal attributes, we may work to a higher plane of excellence But if dermatology as a specialty needs more efficiency, it needs also the means whereby it is to be attained We shall find those means when we find truth If we would be really effective, we must find the truth that so often is hidden from us

What is the truth about dermatitis herpetiformis, or psoriasis, or lupus erythematosus or vitiligo? What is the truth about many of the dermatoses which we bedeck with names that suggest so much wisdom and conceal such appalling ignorance? Our real, our urgent, our vital need is truth, to know what causes all these diseases with the long names

Our duty in the premises is apparent enough Both as individuals and as a section, we should do our utmost toward the solution of the problems of etiology, which constitute, today, our most serious handicap

There are many promising fields for research Among the external agencies, the part played by fungi has probably by no means been realized Concerning possible internal causes, we have gone through so many disappointing experiences with various hypotheses that the mildest suggestion of novelty in etiology at once provokes violent reaction

However much may be said in favor of a certain degree of enlightened skepticism, we must not, through fear of an overswung pendulum, allow the clock to run down We have need of open minds The truth that we are seeking will not be found in the reactionary spirit which mistakes enthusiasm for fanaticism, nor will it be found in the exuberant spirit of faddism Probably it will be found somewhere between the two

In our search for etiologic factors, we now have a list of possibilities, most of which belong exclusively to the present generation It is our duty to exploit them without preconceptions as to their validity I believe that it is fair to propound the following as worthy of complete investigation in every dermatosis of unknown origin focal infection, the sympathetic nervous system, the endocrine glands, protein sensitization and disturbed metabolism It seems not

* Chairman s address read before the Section on Dermatology and Syphilology at the Seventy Third Annual Session of the American Medical Association St Louis May, 1922

unreasonable to suppose that such investigation will add materially to our store of etiologic knowledge

Now, as to our duties Granting that our chief duty is service, we may consider it under three heads (1) service to individual patients, (2) service to society in general, and (3) service to the medical profession

The most valuable service which the dermatologist can perform for the individual is the interpretation of the cutaneous lesion Too often the careless view is held that the skin specialist is solely concerned with superficial lesions of cosmetic importance only It is true of course that many consultations are for the relief of relatively innocuous disorders, but it is equally true that many of the lesions for which relief is sought, in the belief that they are trivial, represent boundary posts on the frontier of serious disease

The interpretation of a given lesion may mean the simple diagnosis of some definite disease, or the recognition of some constitutional condition which, for the moment, is giving rise to no signs or symptoms elsewhere

In such serious conditions as the acute exanthems, precancerous or frankly malignant lesions, and the various forms of tuberculosis, leprosy or syphilis, the diagnosis practically carries its own interpretation There is a large group, however, in which slight cutaneous lesions may signify some grave constitutional condition It is here that we may perform service of utmost value to the individual, if we are complete and accurate in our interpretations

Some lesions point to diabetes, some to cardiac disturbances, some to pelvic disorder, some to the endocrines, and some suggest toxemia, the search for which leads to focal infection

The point cannot be made clearer, perhaps, than by taking, as an example, a case of lupus erythematosus I do not believe that we are doing our full duty in any case of lupus erythematosus in which we are content with a diagnosis plus even successful local treatment Lupus erythematosus is so definitely suggestive of toxemia that, whether it be from a tuberculous lesion or an infection in the antrum, we have not satisfied the moral obligation which we assume in taking the case, unless, in addition to the treatment, we take on the burden of interpreting the lesions in the most complete sense that available evidence allows If we find, for example, an infection of the antrum, we must assume that, whether or not it be in etiologic relation with the cutaneous lesions, it is a potential source of danger, about which it is our duty to advise It is only through the adoption of such an attitude that we can hope to give the same service that we would wish to receive were we in the place of the patient This, after all, would seem to be a fair criterion of service

The medical profession has definite duties to society, in which all the specialties must participate according to their respective abilities No obligation is more important than the conservation of public health Aside from work along broad lines of general preventive medicine, in various aspects of which dermatology is vitally interested, we can serve humanity to no better purpose than in the exposure of quackery

Quackery flourishes on nothing so much as on ignorance The fallacies of former generations concerning the nature of skin diseases still linger in the popular mind, which even today is prone to regard any eruption as evidence of impurity of blood or the stigma of personal or ancestral vice

These misconceptions make a particularly favorable soil for the development of quackery The desire for beauty is also a human weakness which is bounteously catered to in the exploitation of innumerable alleged aids to cosmetic perfection No one knows better than the dermatologist the heavy toll paid by the sufferers from paraffin oil injections, no one knows better the needless unhappiness from experiences with noxious hair dyes, hair removers and even hair growers

To us, the duty is clear It is simply the diffusion of truth In California, a good start has been made by a medical organization which is called the League for the Conservation of Public Health

One of its activities along educational lines is in cooperation with two daily newspapers which devote certain space to medical information Questions are referred through the league to the medical man who is deemed an authority in the subject involved These newspapers are also furnished with various medical articles written by specialists Both in Los Angeles and in San Francisco, it is now possible for the layman to obtain authoritative opinion or guidance concerning any medical problem Thus, our profession is attempting, in some measure, to fulfil its obligation to the community, with respect both to preventive medicine and to quackery

The duty of dermatology to the profession is cooperation While this is necessarily a reciprocal relation, we shall do our part by attempting to keep in closer touch with medicine in general, as well as by correlating our findings with those of internists and of specialists in other lines We owe it to the profession to make known in plain terms the significance of dermatologic lesions as we interpret them We need to write for the man in general practice as well as for our confreres in dermatology

We need to make of dermatology a clearing house for the subject of syphilis While we recognize the interest of the internist and the specialist in other branches, we must insist that the teaching and treatment of this disease is today, as in former times, an integral part of dermatology Before the development of the Wassermann test, there was never doubt as to the destination of a syphilitic patient. Because of the training of dermatologists in the recognition of the objective signs of the disease, the matter was by common consent left in their hands Today, syphilis is diagnosed in the laboratory and is treated by any or by all It is our duty to demonstrate such proficiency in respect to this disease that the profession at large will willingly regard it as belonging to dermatology

There is little need for recapitulation On the seal of Yale University is the inscription "Lux et Veritas" That phrase epitomizes, I believe, both our needs and our duties And for dermatology, my prayer would be that of David "O send out thy light and thy truth let them lead me"

391 Sutter Street

Hookworm Disease in Colombia —According to a recent report by Dr F A Miller director of the antihookworm campaign 53 390 persons were examined during the year 1921, 49,940 (92 per cent) were infected Treatment was given to 47,822, and 37,488 (78 per cent) were cured Up to May 31 1921, all the expenses were paid by the National Health Board of the Rockefeller Foundation but from June 1, 1921 the Colombian government will bear 20 per cent of the expenses The department of Boyaca and Santander del Norte have contributed $5,000 each to the expenses, and the department of Antioquia, $2 000

THE LIMITATIONS OF INTRAVENOUS MEDICATION *

CARL VOEGTLIN, PH D
Professor of Pharmacology, Hygienic Laboratory, U S Public Health Service
WASHINGTON, D C.

Therapy, as other branches of medicine, is subject to influences which, temporarily at least, tend to overemphasize the value of certain procedures However, the gradual accumulation of new knowledge concerning the value of these procedures usually brings about a clearer recognition of their limitations Of recent years, the practice of intravenous medication has come to the front to an ever-increasing extent, and, though by no means a new procedure, its application to the treatment of disease has assumed such proportions that it is both timely and important to consider for a moment the real merits and limitations of this form of therapy

Of course, it is utterly impossible to cover this subject exhaustively in a brief article All I can hope for is to point out some of the pharmacologic principles involved, illustrating them by a few examples, and to leave you in that healthful state of mind which demands proof in every instance before accepting claims in favor of intravenous medication First of all, let us inquire into the reasons for this tremendous increase in the popularity of intravenous injections, for, as in other matters, I believe that the historical development of any procedure often throws light on the cause of its introduction and later practice

HISTORY

Intravenous medication is not of modern origin, on the contrary, it antedates the discovery of the administration of remedies by subcutaneous injection An English student of this subject [1] attributes the discovery of intravenous medication to Christopher Wren, a professor of astronomy at Oxford University, who, in 1656, made experiments on dogs, and showed that medicines could be introduced directly into the veins without disastrous effect I believe that these experiments were the natural result of Harvey's discovery (1628) of the circulation of the blood, and they were probably devised to facilitate the rapid distribution of remedies in the body A year later (1657), the first intravenous injection was made on man, and this was followed by numerous attempts to treat diseases by this method with a great variety of drugs Crude empiricism characterized this period All conceivable substances were injected, indiscriminately A certain Dr Hale of Boston had even the curiosity to inject into his own veins castor oil in order to test its purgative effect Strange to say, he survived long enough to write down his experiences We may look with ridicule on these early attempts, but I dare say that future generations may find amusement in some of our present-day experiments

The modern application of intravenous medication began with Baccelli's [2] introduction of the intravenous injection of quinin for the treatment of malaria (1890) He advocated this method as a routine treatment, on the assumption that the drug is brought immediately into contact with the parasites, whereas, given by mouth, the time required by absorption would necessarily delay the action This was soon followed by Crede's [3] treatment of septicemia by means of intravenous injection of colloidal metals The reports of this period, as of the former, showed, however, that intravenous medication is not without danger, and consequently it did not come into vogue

About twenty years later (1910), the discovery and use of arsphenamin in the treatment of syphilis revolutionized medical practice in this respect Although this drug, given intramuscularly, produced a marvellous effect on the lesions, and caused the rapid disappearance of the parasites, it was soon realized that the local reactions at the site of injection were exceedingly objectionable, so, as a last resort, the intravenous route was chosen, and now, I dare say, millions of such intravenous injections have been given Hence, the intravenous use of arsphenamin and its substitutes has done more than any other single factor to popularize intravenous treatment Whereas, in former years, the average physician regarded an intravenous injection as a minor surgical operation requiring considerable practice and preparation, he now had to familiarize himself with this technic, and so it came about that intravenous injections were made on a fairly large scale by the practitioner Most of the respect for the ever-existing possibility of dangerous reactions resulting from intravenous therapy then vanished, in spite of the fact that careful observers, from time to time, voiced a warning against the careless and indiscriminate use of arsenicals by this route It is surprising, however, considering the enormous number of arsphenamin injections given, that the reports of untoward reactions have not been more numerous

THERAPEUTIC EFFECT

This demonstration of the relative harmlessness of intravenous arsphenamin injections has prompted physicians to apply this method within recent years to other drugs and to other diseases, principally on the assumption that intravenous injection is of necessity followed by a more powerful therapeutic effect than is administration of the drug through other channels The fact was forgotten that the intravenous administration of arsphenamin was simply an attempt to avoid pain and local reaction, and that it was not introduced in order to increase the therapeutic effect I want to lay particular stress on this point, as this misconception seems to be quite prevalent among physicians and pharmacologists, and it is largely responsible for the present popularity of intravenous medication I particularly call your attention to the data furnished by Fordyce, Craig, Harrison, Wechselmann and others which add assurance of the therapeutic efficiency of intramuscular and subcutaneous injection, and, during the last three years, we have been able to establish this fact by well-controlled experiments on animals, using a quantitative method Thus, we showed [4] that the parasiticidal effect of injections of arsphenamin and neo-arsphenamin given intramuscularly is as good as that of the same dosage given intravenously

That this should be so is not at all surprising in the light of some recent work of ours [5] on the mode of action of these arsenicals Arsphenamin of good qual-

ity we believe to be practically nontoxic per se, but, after its introduction into the animal body, there is gradually formed from it, by partial oxidation, an extremely toxic modification (arsenoxid), which exerts its destructive action on the parasites and, to a lesser extent, on the tissues of the host Therefore, we must regard arsphenamin as a drug which, after its introduction into the body, forms a depot of a potential drug When arsphenamin is given intravenously, the depot is more widely spread over the body than when the drug is given intramuscularly, where it remains localized for at least a short time Nevertheless, in principle, the intravenous injection establishes a depot just as does the intramuscular, and the foregoing experiments clearly prove that it matters little, so far as the therapeutic effect is concerned, whether this depot of arsphenamin is scattered all over the body or is confined to one muscle The active modification of the drug "arsenoxid" is formed in both cases, and it reaches the parasites continuously by way of the circulation It is this continuous stream of the active modification, to which the parasites are exposed over many hours, which causes their death

It having thus been shown that arsphenamin when given intravenously exerts no more powerful parasiticidal effect than when injected intramuscularly, and that the intravenous method was chosen in order to avoid local reactions, the question arises Are there any drugs which, under certain conditions, give better therapeutic results when injected intravenously? I believe that we must answer this question in the affirmative, as, for instance, when time is an important element in the treatment or when the drug is not sufficiently absorbed by other channels The intravenous injection of quinin in malignant malaria, of strophanthin in certain cardiac cases, of diphtheria antitoxin in severe diphtheria, is not merely advisable but is absolutely indicated as an emergency measure Under such conditions, the physician cannot afford the delay incident to the administration of these remedies through other channels

With regard to the efficacy of intravenous quinin injections, clinical observers agree that the action in extreme cases is more prompt than when the drug is given by mouth, and the patient's life may thus be saved However, as soon as the critical condition has passed, quinin should be given by mouth for the reason that the available evidence shows that malaria is not more readily cured by intravenous medication,[6] and this is supported by some recent findings[7] which indicate that about 90 per cent of the quinin injected intravenously in man disappears from the blood within one minute, and is stored in the tissues

Another example of the superior therapeutic effect of intravenous medication is the administration of salt solutions in severe hemorrhage

With intravenous medication, the dosage required to cause a certain therapeutic effect is, with several drugs, considerably smaller than if treatment is given by other channels Epinephrin, for instance, produces a much greater rise in blood pressure when injected into a vein than when given intramuscularly On the other hand, the pressor effect is much more prolonged in the latter case, on account of the more gradual destruction of the drug by oxidation If, therefore, we wish to counteract the depressing effect of certain drugs on the blood pressure, such, for instance, as arsphenamin, we choose the intramuscular injection of epinephrin in preference to the intravenous, and this principle holds for certain other drugs with symptomatic or etiotropic action In other words, gradual absorption counteracts rapid destruction and elimination of the drug, and hence insures prolonged pharmacologic action, which often is a therapeutic desideratum

COMMERCIALIZATION

What has been said concerning the superior value of intravenous medication with regard to the therapeutic effect is sufficient to raise a question as to the unscientific claims made by certain commercial interests who advertise a great variety of drugs put up in solution for intravenous use Most of these products have not been included in New and Nonofficial Remedies by the Council on Pharmacy and Chemistry, because they are sold under misleading claims regarding their alleged safety and efficiency[8]

SAFETY

We have so far considered principally the merits of the curative value of intravenous medication, but it is equally if not more important to inquire into the safety of this method of therapy

It is perhaps unnecessary to call attention to the various possibilities of injury to the patient which may follow the use of a faulty technic Asepsis is an essential requirement It is also perfectly obvious that care should be exercised not to inject any air, solid particles or oil droplets, on account of the danger of embolism However, this can be avoided by proper technic and, if necessary, filtration of the solution before injection Furthermore, it is clearly evident that care should be exercised not to allow any of the drug to escape into the perivascular tissues in case such solutions cause local irritation These untoward reactions are under the complete control of the physician It sometimes happens that thrombosis occurs in the vein, which usually makes it impossible to use this vein for future injections

It is, furthermore, of the utmost importance to realize that intravenous medication brings the drug into immediate contact with some vital organs, such as the heart and the central nervous system, and the drug concentration to which these organs are exposed is much greater, at least temporarily, than if the same dose had been given by the usual channels Now, concentration is an all-important factor in drug action All drugs, even the purest distilled water, are poisonous in higher concentration, and their beneficial effect is usually restricted to a range far below the toxic dose Several hundred milligrams of caffein can be given to dogs with impunity by hypodermic injection, whereas 5 milligrams per kilogram of body weight rapidly injected into a vein will cause death by cardiac failure It appears to me not at all surprising, therefore that serious reactions and even deaths sometimes occur from the rapid intravenous injection of such drugs as quinin, arsphenamin and its substitutes and strophanthin

To be sure, the chances for the occurrence of such deplorable results can be reduced, if not completely avoided, by a full realization of the principles involved, followed by logical procedure It should always be borne in mind that the rate of injection of any drug must be slow enough to give the blood a chance to dis-

tribute it as effectively as possible Theoretically, this can be accomplished by giving a relatively concentrated solution very slowly, or by using a very dilute solution No general rules may be laid down to fit every case, suffice it to say that the number of untoward reactions to arsphenamin have been very materially reduced by the now prevalent use of dilute solutions, given slowly by means of the gravity method Clinical experience in this matter has fully corroborated previous experiments made by Jackson and Smith [9] of the Hygienic Laboratory In these experiments, it was shown that the circulatory phenomena which ensue when an arsphenamin solution is rapidly injected into dogs can be avoided if the solution is given very slowly That this should be so is not astonishing, if it is remembered that the proper functioning of the animal body depends on a nicely adjusted equilibrium of the body fluids and also of the tissues

The application of chemistry and physics to the study of these equilibriums has taught us much in recent years We now know that the chemical composition of the blood and its physical chemical properties, such as osmotic pressure, hydrogen-ion concentration and colloidal state, are maintained with remarkable constancy and appear to be essential for physiologic wellbeing Some of the factors of safety which operate in the maintenance of normal conditions have been recognized The hydrogen-ion concentration, for instance, is kept at a certain level by means of the so-called buffer value of certain blood constituents, which neutralize any excess of hydrogen or hydroxyl ions introduced into the body It is this mechanism which protects us under ordinary conditions against alkali or acid intoxication, so that we can take with impunity a considerable amount of alkali and acid with our food Here again, however, we are forced to consider the rate of introduction A certain amount of alkali which is well tolerated when given by mouth may prove fatal when injected rapidly intravenously, and, as Jackson and Smith [9] point out, the acute circulatory reactions following the intravenous injection of alkaline solutions of arsphenamin may be largely due to the excess alkali, which may irritate the myocardium or the blood vessels

In this connection, I can refer you to some unpublished experiments by Dr M I Smith, which demonstrate the injurious effect of a rapid injection of sodium hydroxid He found that, in cats, approximately 0 25 c c of a normal solution per kilogram of body weight caused a precipitate fall of blood pressure and complete circulatory collapse These experiments may possibly be of significance in connection with the careless overalkalization of arsphenamin solutions It would, therefore, seem highly desirable to develop proper buffer solutions to use with arsphenamin

Again, as regards the colloidal condition of the blood, information is rapidly accumulating pointing to the danger involved from the injection of foreign colloids into the blood stream Only recently, a death has been reported from the intravenous injection of acacia,[10] a drug which was advocated, during the war, for combating severe hemorrhage and surgical shock Foster and Whipple [11] have also pointed out that acacia injections decrease the coagulability of the blood and the regeneration of blood fibrin, and Hanzlik and Karsner [12] have demonstrated the production of emboli and thrombi in the pulmonary vessels of guinea-pigs

In the earliest days of the use of arsphenamin solutions, Wechselmann discovered the so-called "Wasserfehler," an acute reaction of the patient due to the presence of bacterial protein in the water used for making the drug solution Moreover, Hunt [13] attributes the higher toxicity of freshly prepared arsphenamin solutions as compared with those which have stood or are heated for a short time, to the physical chemical properties of the former Colloidal reactions between the drug and certain blood constituents may very well be responsible for these phenomena Some recent work has shown that arsphenamin solutions approach the true colloidal state and it is obvious that in a neutral medium such as the blood, arsphenamin could not exist in true solution for the reason that the arsphenamin base is completely precipitated at the neutral point In the case of this drug, therefore, the conditions under which it is used for injection are of the greatest practical importance

Several instances have come to my attention, even recently, in which the physician used by mistake the hydrochlorid instead of the alkaline solution, with disastrous effect The injurious action of the hydrochlorid is probably due to the tendency of the hydrochloric acid of the drug to cause intra vitam precipitation of the free base or of a combination of the free base with blood protein Acids are generally known to cause an aggregation of amphoteric colloids such as proteins and arsphenamin, whereas alkalis tend to cause dispersion As a matter of fact, Joseph [14] has actually demonstrated the presence of such arsphenamin precipitates in the blood of animals injected with the hydrochlorid, whereas he failed to find them after the use of alkaline solutions of arsphenamin

Another possibility for the production of reactions may perhaps be found in the use of large volumes of solutions improperly adjusted as to osmotic pressure Hypotonic solutions of sodium chlorid given rapidly were shown, by Weed and his collaborators,[15] to cause a great and sudden rise in cerebrospinal fluid pressure Is it not possible that some of the symptoms which may follow the use of large amounts of drug solutions improperly adjusted in this respect and rapidly injected, especially under pathologic conditions of the central nervous system, could be attributed to sudden changes in cerebrospinal fluid pressure?

To sum up, it appears that a considerable amount of evidence has accumulated in recent years which indicates that the nicely adjusted equilibriums of the blood and those of the easily accessible tissues may be temporarily upset by intravenous medication, and this disturbance may give rise to undesirable symptoms and even cause death

These symptoms are due to various causes, some of which have already been clearly recognized In many cases, untoward reactions can be avoided by introducing the drug solution at a slow rate, which permits the protective mechanism of the blood and tissues to operate *efficiently*, whereas, *if the injection rate is too fast*, this mechanism breaks down, and symptoms appear as visible results of the disturbance of the chemical or physical equilibrium of the blood and tissues

Under certain pathologic conditions, this equilibrium is more easily disturbed I shall only refer to the increased possibility of producing reactions in case of diminished functioning of the excretory organs It is a common practice to test kidney function before and during a course of arsphenamin or its substitutes, for obvious reasons

In special cases, previous treatment with a drug which produces a cumulative effect has also to be taken into account In a case of malignant malaria which is treated intensively with quinin by mouth, it is decidedly dangerous to give the intravenous dose of quinin ordinarily recommended for this purpose without first allowing the patient to dispose of the drug previously given, and this is equally true of the arsenical treatment of syphilis, and of the intravenous use of strophanthin in cases which are under treatment with digitalis by mouth

Having seen that intravenous medication is not necessarily superior therapeutically to other modes of drug administration and having pointed out the numerous possibilities of injury to the patient inherent in this method, we should strive to simplify the technic of the administration of drugs wherever possible, in order to avoid the necessity of the injection of the medicament directly into the circulation The subcutaneous injection of morphin and similar drugs is an exceedingly simple procedure, which very often is left to the attending nurse Would it not be a great step forward if such drugs as arsphenamin or its substitutes could be given subcutaneously?

During the last year, in collaboration with Miss Dyer, Dr Johnson and Mr Thompson, I have studied such a preparation experimentally, and so far it meets all the essential requirements It is prepared from arsphenamin, formaldehyd and sodium bisulphite, its aqueous solutions are very stable and do not increase in toxicity on standing for twenty-four hours or on vigorous shaking Its parasiticidal effect is extremely constant, and it does not cause any local reactions if injected hypodermically The chemotherapeutic index or, in other words, the ratio between the curative and the maximum tolerated dose is as good as in the case of arsphenamin The drug is now being tested clinically, and, should our hopes be fulfilled, I believe that it will have a considerable effect on the practical problem of the control of syphilis, for it stands to reason that such a preparation would make it possible for physicians who have not the required experience with intravenous arsphenamin treatment to give the treatment in this simple manner, if necessary under the general supervision of an experienced syphilologist, as advocated recently by Stokes

DISEASE CONTROL AND PREVENTION

I believe that it should be emphasized in this connection that intravenous medication, of necessity, places decided restrictions on the treatment as well as on the prevention of certain diseases, on account of the more or less difficult technic inherent in this method Take, for instance, the problem of the control and eradication of syphilis, it surely stands to reason that a simple technic of treatment, such as the subcutaneous injection, would make it possible to put a larger number of syphilitics under the controlling influence of the arsenicals, and this would unquestionably help in checking the spread of this disease, and it might also assist in its eradication

Again, the practicability of the prevention of malaria by means of the oral administration of quinin rests exclusively on the fact that it is possible to produce a prophylactic effect by taking quinin tablets by mouth, and I doubt whether anybody would claim that the prevention of this disease could be made a feasible proposition if quinin had to be injected intravenously for this purpose Therefore, every effort should be made to render the administration of such drugs as simple and safe as possible, without, however, sacrificing their therapeutic efficiency Intravenous medication to my mind, will never serve this purpose, and will always have a more or less restricted field of usefulness

---

THE REAL THINGS IN MEDICINE*

HUBERT A ROYSTER, A B, M D
RALEIGH, N C

The minimum requirements for a career in medicine are a preliminary education, four years in a medical school, and a license to practice While these requirements are indispensable, they are by no means sufficient Three higher attributes stand out as real elements that make for a successful physician, without these, real success in medicine is impossible brains culture and character

BRAINS

Brains are the alpha and omega of the man of medicine We all recall the artist who, when asked what he mixed his paints with, replied "With brains, sir" Not long ago when I was on the way to talk to college students on medicine as a profession, the wife of one of the faculty said "Tell them that the one thing they ought to have is brains" She had made my speech To begin the study of medicine without two good cerebral hemispheres thickly covered with a deep cortical layer is to invite failure No encouragement should be extended to those about to enter the profession of medicine or to those already in to continue, unless they are supplied abundantly with gray matter The misfits in medicine, as well as in other occupations, are due largely to a lack of understanding There are some in the cornfield who ought to be in medicine there are some in medicine who ought to be in the cornfield

The study of medicine bestows no more brains and adds not one cubit to the mental stature It provides only a few more implements of the mind to be used for good or for ill Unless the roots are deeply planted in the soil of real learning, the study of any science narrowly pursued takes away from the natural resources of the mind more than it puts in In other words, a finely endowed intellect is needed to carry on in the realm of science, to withstand its temptations toward the illogical, to keep clear headed in the midst of fact and fancy

Such endowment comes not from science itself, it issues permanently from a mind nurtured in the ways of thinking The handmaiden of brains, essential for the physician, is common sense, which is simply the ability to put brains to good account In the words of Holmes, 'Science is a first-rate piece of furniture for a man's upper chamber if he has common sense on the ground floor But if a man hasn't got plenty of good common sense, the more science he has the worse for his patient"

* President's address read before the Medical Society of the State of North Carolina Winston Salem April 25 1922

CULTURE

Make no mistake about culture Culture is refinement accuracy, poise, resourcefulness, it is not effeminacy, weakness, conventionalism, impracticability We have been getting too far away from the humanities, from classical education, from academic scholarship, if you please In the quest of science—and there is no nobler pursuit—we have set up utilitarian courses, called premedical and certainly premeditated, for the purpose of reducing to a minimum all those things which do not bear directly on the matter in hand, and swelling to a maximum those that are concerned in the material things of medicine In this we have left out the very bed rocks of learning the capacity to interpret the phenomena and the power to express the findings If the average trained laboratory worker in our country today has any weakness, it is his inability to convey his ideas, to put down what he has done, to express his results in terms clear and terse Generally his work surpasses his words And it is not the misfortune of the individual, but of the plan which essays to substitute scientific research for sound scholarship, to get the one without the other, when we may have both It is the common failing of the later generation of medical men that they do not write so lucidly or think so accurately as those just before them There are, of course, numerous and notable exceptions But the observation is probably correct and its explanation lies in the small stress placed on actual scholarship required of one entering the profession of medicine

We are living in an age of inaccuracy We are inaccurate in thought, in speech, in spelling, in writing We know a great deal, but do we know anything very well? Short cuts and practical preparation are the order of the day Language, the only medium through which thoughts are given out, has been almost forgotten Will it be considered very old fashioned if I should suggest that the neglect of the languages, and particularly the banishment of Greek may be responsible for our loose thinking and our lack of scholarship? The value of Greek for the medical student might be a theme for a discourse in itself If you should go over the evidence, you would be surprised to find how much medicine owes to the Greek language, what a very large number of our words referring to diseases, operations and organs are derived from the Greek—fully as many as from Latin And many of those coming through the Latin were taken originally from Greek "We suspect, too, that our men of science who are supposed to be opposed to 'so much Greek must study that language secretly or they assuredly could not name the tools of their own trade"[1] The chief advantage of the study of Greek is a training in accuracy, in the expression of nice shades of meaning, the very essence of a cultivated mind engaged in scientific thought We cannot divorce science and culture, we cannot go on rearing a race of seekers after truth who are not trained thinkers, we cannot fail to perceive that the education of a candidate for a learned profession means for us, as it has meant for all the older nations, a thorough grounding in the ancient and honorable arts and classics before we approached the special study needed for our dignified calling That way trod our great fathers, who outstripped us with the means at their disposal, that way lies our hope of elevation, of bringing back the well rounded medical man and adding to him the marvelous scientific attainments of the present age My thought was expressed by Thomas L Stedman,[2] in these words "Some day the pendulum will swing the other way and a new renaissance will once more join culture to knowledge to make the perfect physician"

CHARACTER

Detracting not one whit from the appeal for better mental equipment it appears even more timely to emphasize the greater need for moral qualification in the physician By this no reference is meant to righteousness or to worlds to come, to religion or to denominationalism, but only to the possession of a sound moral sense The character of a physician is his most priceless property It is what he stands for and whom he stands with, it is his attitude toward life, it is "what God sees him do in the dark" Truth is the goal, it develops character, and character tells in one's work Too many are entering the medical profession without good working consciences, without a keen appreciation of the difference between right and wrong, too many are coming into an honored and honorable calling with low standards of trade and traffic in their souls, too many get in who are not gentlemen to begin with and cannot be made gentlemen to end with Today the young physician too frequently feels compelled to ask his associates, 'What do I get out of it?" when he might better ask himself, "What am I putting into it?" Greatly to be desired is a stronger effort to train the moral perception of medical students They must be inspired toward a high-minded estate In the speech and bearing of graduates of certain medical schools can be recognized just exactly the outlook on life and the regard for our profession held by their teachers It is an unconscious percolation The fine sense of intuitive right-thinking and truth-loving can shine through both precept and example Morals cannot be legislated into people, but ideals can be educated into them

PREPARATION FOR THE PRACTICE OF MEDICINE

My tribute to science is the greater because of my contention for broader preparation before embarking in its service I heartily join with Moses Harvey in saying that 'science is teaching man to know and reverence the truth and to believe that only so far as he knows and loves it can he live worthily on earth, and vindicate the dignity of his spirit" Medicine is both a science and an art, it has to do both with knowing and with doing It is not an exact science—more's the credit, for exact sciences are inert and uninteresting But the one big asset for the medical man is the acquisition of the scientific attitude in his student days Every physician should remain a student the whole of his natural life A pitiable sight is the practitioner who was known as a 'good student" but who, after five years more or less, has degenerated into a routinist, never reviewing his former knowledge or adding to his original store Such a man, though perhaps skilled in so-called practical affairs, forgets more and more medicine each year, until finally it is difficult for him to keep up He begins to decry theory and to extol practice, he thinks only of results and never of causes, he speaks magnificently of "common sense" and letting Nature take its course," but rarely uses the one or permits the other

The trouble with this type of person is that he has never acquired the scientific spirit He fell short in the

1 London Saturday Review Aug 16 1913

2 Stedman T L A Practical Medical Dictionary New York William Wood & Co vii

early approach and missed the mental hole The eager student loves learning for its own sake and believes that no knowledge is useless, if it is correlated He understands that science is organized knowledge The scientific attitude means that nothing must be accepted unless it is known, that nothing can be known until it is approved, that everything shall be met in the spirit of hesitant belief This smacks of pessimism, and one poet at least has been led to exclaim

> O, star-eyed science! Hast thou wandered there,
> To waft us home the message of despair?

But nothing could be more unjust It is not despairing to search for the truth The challenge is, "How much do you know?" and "How can you prove it?" The doubting Thomas has a place here

What has no place in science is the *post hoc, ergo propter hoc* habit of mind It is the most dangerous of all doctrines for the medical man It is the rankest empiricism and furnishes the platform for all quacks and impostors "Whereas I was blind, now I see" is an insidious appeal to effects in utter disregard of the means—the cry of the charlatan Montaigne wrote that when a man is sick and gets well, he cannot say whether it was because of the remedies used, the lapse of time, or his grandmother's prayers It requires a powerful mental effort to get away from the belief that whatever happens after an event is always on account of it, but we must get away from this belief or we shall not retain our clear thinking

After all, it is the acquisition of knowledge which is enticing and inspiring, not merely the possession of it "If I held truth captive in my hand," says Malebranche, "I would let it fly that I might again pursue and capture it" And it is well to remember that not all the new is scientific, nor all the old empiric Science teaches us to unlearn many things each day and to relearn as many the next, for there is scarcely anything new except what has been forgotten

GROUP PRACTICE

A turn in the affairs of medicine is just before us Whether that turn will be toward new and untried fields or along some old and well-worn paths, the future —the near future—will determine The struggle is on between medicine as practiced by the private physician in the time-honored relation, and the practice by groups in a collective fashion No matter what may be the arguments on the one side or on the other, the situation will work itself out precisely in accordance with the desires of the public, the results of methods in use and the attitude of physicians

Owing to the multiplicity of technical detail and the accumulating mass of new discoveries in modern science, it is now more than ever true that no man diagnoseth to himself It was never true that any one man, looking at the patient through the peephole of his slender specialty, could compass a complete diagnosis, or that a cursory inspection in the old way by the ordinary practitioner would round out a survey of the case But always there has been a demand for the man who could find out everything there was to know about his patient, whether or not he himself could carry out all the detailed investigations and therapeutic indications The main reason for requiring assistance in the diagnosis of disease is the need for particular apparatus, in the use of which some are skilled, to elucidate findings not brought out by the general physical examination Thus grew up specialism and thus were developed instruments of precision But there never has been, and never will be, anything to take the place of cultivated brains and trained special senses This dual instrument, ready for instant and proper use, will be found as the principal equipment in the office of the real physician Hear a layman's view [3]

> The real pest among reputable physicians is the young man who expects his patients to pay for his needlessly high overhead expenses He may be known by his spacious and elaborate offices and waiting rooms, buttoned door boys sleek secretaries, fluttering office nurses and powder monkeys of both sexes and an all pervading shimmer of white enamel, mechanical novelties and glittering metal work Not infrequently the young practitioner who indulges in all these fripperies is trying to put over a poor piece by costly stage effects He sometimes forgets, and his patients still oftener fail to realize that what he really has for sale resides in his own cranium and that mere style, atmosphere and scenery are poor substitutes for knowledge, experience and technical proficiency

Unguided by intellect, instruments of precision become instruments of confusion, for they are not infallible and are wofully subject to the human equation Rightly used and rigidly interpreted, they mean much in proving a diagnosis, regarded as the only means in arriving at conclusions or depended on as unfailing agents, they are but disappointments Great pity should be felt for the inexperienced beginner who expects his microscope, his hemocytometer, his cystoscope, his chemical reagents and his metabolimeter to solve all the mysteries of diagnosis and to spell accurately the name of the disease If I should see any such, I would say "Let us first take a look at the patient, use our minds in obtaining his story, perform a laying-on of hands, after which we will ask for the aid of scientific apparatus which may either confirm or reject our observations And if the laboratory findings do not agree with the clinical signs, then so much the worse for the laboratory"

And what will become of our specialism? Where will it end? Will there be need for its regulation and control? Undoubtedly the existence of specialties is the proof of their necessity, and their development has been the crowning achievement of modern medicine But increasing subdivisions of specialism give us pause, so much so that by reaction we are beholding a newer specialist—the general practitioner He is in a class by himself, left in charge of those who are actually sick, with the issues of life and death on his hands, both early and late He is the keystone of the medical arch, without his support the whole fabric would fall, family after family are depending on him for counsel, relying on his judgment in every crisis Of what use are specialists unless there is the intermediary to say when they are needed? And since the general practitioner has by distinction become a specialist and expected to know a little about everything, why should not the professed specialist be required to know something of general medicine? One finds oneself somewhat in agreement with the recently suggested proposal that examining boards may require five years in general practice before allowing the privilege of going into a specialty How else may be curbed the tendency to divide the body into compartments for seclusive attention without a working knowledge of the whole system? These questions also will furnish their own answers

3 Saturday Evening Post

Many are rushing into group medicine as a solution of the whole matter Such practice brings to bear upon each case the combined study of a number of specialists, who, examining the patient individually, finally come together for establishing a complete diagnosis, or leave it to one member of the group to pronounce the judgment Work in groups has come to stay, for it is inevitable that men will associate for mutual help and encouragement Team work is the modern slogan, and it is the way to win the game But if the group discounts the individual and the individual forgets the patient, we have, not group medicine, but gang medicine, and their product is syndicated science, than which nothing could be more unscientific One very notable group clinic and several others of lesser fame and more recent date have served to popularize the combined method of practice, and diagnostic groups are springing up all over the land There are some with only two men in them (reminding us of the close corporations in which one partner is the president and treasurer, and the other, vice president and secretary) and others containing scores of men, there is the peripatetic clinic, in which taxicab fare is a considerable item, there are those conducted under one roof either of a separate institution or on one floor in an office building, there is the community hospital with its broad choice of consultants and naturally a subgrouping among these While there is much to be said in favor of any form of associated effort certain fallacies and dangers lurk in group practice Primarily it is well to recall that "a chain is no stronger than its weakest link," and unless the men on the team are of equal capacity in their several branches, the resultant report will be onesided There is danger, too, of everybody's business being nobody's business, so that the diagnosis produced may be a compound of the average forces of a factory, ground out piecemeal An impersonal mark is likely to attach to all such methods to rob the process of any human touch and to afford the greater chance of error, especially if the interpreter for the group sees the patient only for a short sitting on the last day of the ordeal Of necessity, the head of an important group is compelled to be a genius in his sphere, and all groups which have succeeded scientifically have had such heads

Free and frequent discussion has waged over the group question and its allied problems My feeling is that the group idea is one of the most useful modes of service in medicine But no group should be iron clad or unwieldy, its tendency to send out machine-made work should be changed into that of a hand-picked product, it should stop straining at gnats and swallowing camels, and learn that the group was made for the patient not the patient for the group Just as strongly should we realize that the practice of medicine will never—and should never—get away from the personal relation of patient and physician, and that always we shall depend for our health and our happiness on the daily visits of the physician from house to house,

> Battling with custom, prejudice disease
> As once the son of Zeus with death and hell

ADJUSTMENT TO CHANGING CONDITIONS

A spirit of uncertainty pervades our rank and file The existence of a subconscious fear that something or somebody will take away pristine rights, privileges and emoluments cannot be doubted Nor can it be denied that this fear is natural and justified by appearances What with welfare boards, full-time instructors in health, community service vital statistics laws, narcotic restrictions, prenatal clinics and the like, physicians have begun to feel that they are "preached to" overmuch, that they are "regulated" beyond endurance, and that their confines are being invaded Such expressions are heard in different quarters from time to time Much as we may sympathize with them, the truth is that the fear which they denote is unfounded We shall not lose anything unless we divest ourselves of it, we shall not have anything taken away from us, unless we prove unworthy to keep it, we shall not fail to receive any reward unless we sidestep the labor and the waiting necessary to secure it The only harm that can come to us is the harm we may do ourselves by sins of omission and commission The upsetting questions most of us are asking ourselves are What are we going to do about it? where will the encroachments cease? how shall we adjust ourselves to the inevitable conditions? I will tell you what we are going to do We are going to change to progress We shall go forward, we will meet and master every disturbing difficulty

I have appealed to the fellows of the various component societies to keep in mind the county as the unit of organization and to remember that, for our common interest, attendance is the keynote, and cooperation the watchword, I emphasized the importance of the district societies and approved of plans to conduct their meetings according to a definite program, regarding them as miniature state societies, I sought to dignify the position of councilor, to exalt the duties of this officer, representing as he does in his district the power and influence of the parent organization Finally, each member was urged to feel that the whole structure of organized medicine in state and nation hinged upon his own local status

CONCLUSION

I have an ideal to express for this society First, I would have it conform in every particular to the specifications set forth in Article II of the constitution adopted in 1903, which stated that "the purposes of this society shall be to federate and bring into one compact organization the entire medical profession of the state with a view to the extension of medical knowledge and to the advancement of medical science, to the elevation of the standard of medical education and to the enactment of just medical laws, to the promotion of friendly intercourse among physicians, and to the guarding and fostering of their material interests, and to the enlightenment and direction of public opinion in regard to the great problems of state medicine so that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of disease, and in prolonging and adding comfort to life" I would have this society embody these principles in the conscience of its every member, especially recalling the significance of the order in which the principles are presented, I would have it a place where righteousness reigns and no mean thing may live, I would make it a guild and not a trade union, I would keep it a haven where politics doth not enter and where selfish exploitation doth not corrupt, I would wish every one to think of not what the society is to give him, but what he is to give the society, I would want it a communion where freedom rules, where each fellow may have the aspiration and the opportunity to develop what is in him, but I would also carry its standard so high that we may

draw all men up to it and never for one moment trail its colors in the wretched dust of the unqualified and the unfit

We have every reason to feel encouraged My note is one of optimism If only we may glorify brains as the consummate need, if we reverence culture as a means of grace, if we set character above circumstance, then indeed shall we grow in capacity, refinement and virtue, assuming our rightful stations as devotees of a learned profession and champions of the real things in medicine We cannot fail, we cannot lag behind, if we serve these purposes May we not all stamp deep down in our minds and hearts the cheering message of our first president, the immortal Strudwick, who seventy-two years ago, gave voice to these lofty words

Neither the apathy of friends, the cold neglect and deep injustice of legislation, nor pampered quackery and empiricism can stay its onward course True medical science will like the majestic oak, withstand the shock and storm of every opposition It has been beautifully compared to a star, whose light, though now and then obscured by a passing cloud will shine on forever and ever in the firmament of Heaven

SIGNIFICANCE OF THE EXTRINSIC MUSCULATURE OF THE LARYNX

ITS RELATIONSHIP TO CERTAIN DISORDERS OF THE VOICE *

ELMER L KENYON AB, MD
CHICAGO

During the twenty-four centuries of historical knowledge of the developments in laryngeal physiology long periods, even of centuries, have elapsed during which no advancement in knowledge of the laryngeal function is known to have been recorded And it may not be without a useful purpose to note here that evidence is not wanting to cause one to wonder whether the laryngologist may not now be passing through one of these listless, or self-satisfied, periods with respect to laryngeal physiology An examination of numerous recent laryngeal textbooks and general physiologies seems to warrant such a fear One turns over the accounts of the physiology of the larynx in textbook after textbook without encountering any reference at all to physiologic knowledge of the larynx of the first importance, knowledge already nearly or quite a half century old Such neglect of the very bases of laryngeal knowledge can but serve to retard progress in certain phases of laryngeal therapy

If we are to understand the function of the larynx, it is first necessary to understand what the larynx is, both anatomically and physiologically The anatomic definition is arbitrary and limits the meaning of the term to the laryngeal box itself, including the epiglottis But a physiologic definition admits of no such arbitrary limitation The physiologic larynx must be defined as the entire physiologic mechanism on which the movements of the vocal cords depend

The laryngeal box is not only a suspended organ, movable upward and downward (through a range of about 3 cm) and in all other directions, excepting directly forward, to an important though limited degree, but it is movable only with, and as a part of, the hyoid bone, and the base of the tongue, and even of the lower jaw and floor of the mouth Particularly, the larynx, hyoid and base of the tongue cannot but be considered as a physiologic entity The larynx is suspended from the hyoid bone, the hyoid from the base of the tongue, the tongue from the lower jaw and the skull All three are intimately involved in a complicated musculature whose action alters their relationship to each other and to the fixed bony structure of sternum, spinal column and skull The component parts of this musculature are so numerous and the musculature is so complicated that a complete understanding of the combined movements requires much more investigation than has been undertaken up to this time But one fact is not hard to make out, namely, that all parts move together and in harmony to produce even the simplest attempt at phonation by the vocal cords They constitute definite factors in vocal cord physiology and all must be considered as belonging to the physiologic larynx

The first definite statement which I have found in the literature, conveying the thought that extrinsic muscular action is *always* an accompaniment of vocalization, is that made by John Wyllie,[1] in 1886 In discussing the mechanism of pitch production he says, "The position of the larynx varies with every note"

Reliable studies of the relationship of the extrinsic muscular action to the movements of vocal cords were made by Brucke,[2] in 1856 von Meyer,[3] in 1884, and John Howard,[4] in 1886, as well as by others

Nature approaches the problem of vocal cord action in no partial or haphazard spirit She approaches it rather with all the needs of vocal and musical physiology well in mind The demonstration of this truth lies in the fact that no central nervous plan of laryngeal action has been provided excepting that which compels the coordinating action of all the complex musculature of the larynx, both intrinsic and extrinsic We, as human beings, are not afforded a nervous control of the intrinsic muscular mechanism alone The nervous centers of vocalization which we may employ are only those which control the fifty or sixty distinct muscles, intrinsic and extrinsic, all of which must function for the simplest vocal act

The fact that combined action of the intrinsic and extrinsic muscular systems of the larynx is necessary for vocalization is further demonstrated by their instinctive united employment in producing the laryngeally produced crying sounds of the babe as he enters the world

Only by harmonizing these two great physiologic facts, the production of voice by the adjustment and vibration of the vocal cords, immediately due to the action of the intrinsic muscles, and the constant coincident extrinsic movements of the laryngeal musculature, is it possible to understand the physiology of the larynx

The immediate basis of vocalization lies in the manner of adjustment of the vocal cords to each other Definite adjustments of the cords for pitch production

* Read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Wyllie John *Disorders of Speech* 1886 p 475
2 Brucke Grundzüge der Physiologie und Systematik der Sprachlaute Vienna 1856
3 Von Meyer G H The Organs of Speech New York 1884
4 Howard John The Physiologic Basis of Artistic Singing Boston 1886
5 The motor centers for the speech function control at the same time the function of chest contraction and expansion If the muscles of the chest were included in the foregoing estimate it would be found that the action of approximately 100 muscles was required for the production of any manner of vocalization

through a range of about two octaves is required At the same time, definite adjustment of the vocal cords for the production of overtones suited to each voiced sound (if not also to each voiceless sound) must be provided When one realizes that the mechanism of adjustment for each voiced sound must be able to maintain itself through a long range of pitch elevation and depression, one may begin to comprehend the complexity of the required vocal cord adjustments They must be almost infinite in number Differences of tension of thickness, of adaptation of parts, of manner of vibration, must succeed one another endlessly None excepting a human mechanism could begin to have such complexity and diversity of action Each muscle, intrinsic and extrinsic, must play its related part, ever changing in action as the need changes, cooperating with a more or less strength of action, much as each instrument of a large and finely governed orchestra must adapt its action to the instrumental purpose of the whole

If one now also conceives of the other aspect of the production of speech and song, that of enforcing through resonance the sounds created in the larynx, and if he realizes that a part of the extrinsic musculature which is concerned with vocal cord adjustment is employed also for resonantial adjustments, one is in a position to realize the full complexity of this function The object of resonance adjustment is to so shape the movable walls of the resonance spaces as to adapt them, in size and form, to best reinforce the overtones already definitely produced in the larynx Thus, the base of the tongue and the hyoid musculature is ever conforming its action to the needs of the vocal cord adjustments, at the same time, never forgetting its relationship to resonantial adjustments

Certain larger principles of action of the extrinsic musculature of the larynx may be expressed thus

1 The extrinsic musculature may be roughly conceived as determining the larger relationships between thyroid and cricoid cartilages, and, thus, between thyroid and arytenoids, while the intrinsic musculature determines the finer adjustments of the vocal cords themselves

2 Each plan of adjustment between cricoid and thyroid alters the relationship of each of these cartilages to its next neighbors and requires new muscular adjustments to meet this alteration, and so on to the next neighbor, until the fixed bony structures have been reached Each muscle of the entire system must thus enter into the plan for any particular vocal cord adjustment

3 The entire suspended mechanism must be steadied with respect to each element in the series, and all must be steadied against the fixed bony structures

4 The question of resonance spaces for the various sounds of the language, as well as for musical purposes, must ever be given attention, in part by many of the muscles that require adjustment to the needs of action of the vocal cords themselves

The aphonic voice (which appears to correspond with the whispered voice) is also produced by the combined action of the entire laryngeal physiologic musculature Brucke was the first to point out that the whispered voice had its origin in the larynx While the exact action of the intrinsic structures of the larynx for the whispered voice is less clear than that for the loud voice (which also is largely a matter of surmise) it is evident, at any rate, that, while the mechanism of adduction is more or less in action, the mechanism which tenses the vocal cords is not in action The sound that is produced in the larynx in whispering is that of air passing over vocal cords, usually at any rate partly adducted, but not accurately stressed

The extrinsic musculature is likewise in action for the whispered voice, in general corresponding to the action of this musculature in the production of the loud voice, but in certain details differing from it The most striking difference in the action of the extrinsic musculature is its intensity of action (as determined by palpation) in the production of the loud voice as compared with its light action in the whispered voice But another striking difference is the uniformly high position of the thyrohyoid region in the production of the ordinary whispered voice, as compared with the low position in the corresponding loud voice

The high position of the thyrohyoid region required for the production of the higher pitched sounds, as compared with lower pitched sounds, whether loud or whispered is a matter of common knowledge Its explanation has received considerable attention and doubtless requires much more Its chief effect seems to be to tilt the thyroid cartilage on the cricoid, thus increasing the distance between the two ends of the vocal cords [4]

Normal adduction of the vocal bands is both neurologically and physiologically a very different procedure from abduction Physiologically, adduction demands action not only of the adductor intrinsic musculature but also of the entire extrinsic musculature Neurologically, it demands the innervation not only of the recurrent and superior laryngeal nerves, supplying the intrinsic musculature, but also of all the nerves supplying the fifty and more extrinsic muscles [6]

On the other hand, abduction consists simply in the relinquishment of the adductor activity, and the outward movement of the cords under action of intrinsic muscles alone Abduction depends, then, solely on the recurrent laryngeal nerve for its innervation

In explaining some practical diagnostic and therapeutic uses which a knowledge of the extrinsic musculature of the larynx affords, it may be said that these uses are founded mostly on two facts (1) that any large abnormal activity of the extrinsic musculature is determinable by palpation, and (2) that general determination of the management of this musculature is partly under control of the will

The pathologic aphonic voice may, as all laryngologists know, result from two main causes (1) local intrinsic conditions which prevent the approximation or else prevent the tensing of the vocal cords, although the general physiology of adduction be otherwise operating normally, and (2) failure of the cerebral centers for the loud voice to function In either case, the quality of the tone becomes whispered, or aphonic

Much confusion may be avoided in making the differentiation between these two pathologic conditions, if we bear in mind that the aphonic voice from central causes may be readily and definitely diagnosed by palpation of the thyrohyoid-base-of-tongue region, while the patient is phonating In case of aphonia from central causes, one may thus readily learn that

6 Not to speak of the nerves supplying the compressive muscles of the chest which must also act in harmony with the adductor mechanism

the mechanism for the loud voice is not functioning, but is being replaced by the mechanism for the whispered voice, while, if the cause of the aphonia is due solely to local intrinsic laryngeal causes, the extrinsic mechanism for the loud voice will be found by palpation to be operating, although the voice is whispered. One, of course, must be on his guard against the possibility of both causes, local laryngeal and cerebral, being in operation at the same time.

The falsetto voice of puberty, which is dependent on psychologic misconception, or disturbance, consists in the maintenance, by sheer muscular wrongness of action and overaction, of a strained speaking voice higher in pitch than can be normally produced by that particular vocal apparatus. The condition may usually be diagnosed by the thin, strained, monotonous, excessively high pitched quality, in connection with the history. But for confirmation and clarification of the diagnosis, especially if a doubt exists, and also for purposes of treatment, the external musculature of the phonating larynx should always be palpated. In the production of the normal voice, this mechanism acts with a free upward and downward action of the thyrohyoid structures, dependent on the sounds being produced, and the pitch of their production. But, in the habit tensed falsetto voice, these structures are held constantly and rigidly against the highly raised base of the tongue. The entire physiologic musculature is thereby compelled to operate under the handicap of a muscular mechanism steadily and rigidly overacting to produce a false high pitch. This faulty mode of action is readily diagnosed by intelligent extrinsic palpation.

The correction of the falsely produced voice in this disorder is dependent on the education and training of the sufferer to direct normally the physiologic muscular mechanism. In early cases, this is usually relatively easy. In cases of long standing, with the resulting weakness of insufficiently used muscles, and the fixedness of long habit, the return of the voice to normal requires both time and vocal knowledge. In any case, the consideration of the extrinsic musculature serves best as a basis for the training required for correction. The patient is taught to compare by palpation the action of the normal larynx with that of his own. With this knowledge as a basis, he is taught the art of lowering the position of the larynx while talking, as a concrete necessity for the lowering of the pitch.

In still another class of disorders of the voice, dependent on emotional causes (and not as yet, so far as I know, given a description or classification in the literature), one meets with a similar tendency to strained upward action of the elevators of the larynx, and here also, from both a diagnostic and a therapeutic standpoint, a specific knowledge of the extrinsic physiologic laryngeal musculature is important.

Finally, in dysphonia spastica, similar phenomena in the external musculature are observed, but in a more severe and uncontrollable form than in any manifestation of a similar disturbance. The moment such a patient starts to talk, a intense uncontrollable overaction of the elevators of the larynx takes place, constituting the dominating musculature feature of the disturbance. A concrete understanding, through palpation, of the faulty action of the extrinsic musculature has much the same diagnostic and therapeutic use and importance as in the habit-produced falsetto voice. I have recently succeeded in bringing about recovery in a case of this character (where recovery is very rare), through a plan of training, founded largely on teaching the patient how to control the extrinsic muscular mechanism.

The finer control of the voice, especially for artistic purposes, is dependent on three primary factors: (1) the maintenance, by trained action of the chest musculature, of a controlled and adequate air pressure against the vocal cords, (2) the trained coordination of the entire laryngeal musculature, extrinsic and intrinsic, to adjust the vocal cords to receive accurately and adequately the air pressure from the lungs, and (3) the accompanying adjustment of the same and related musculatures to so shape resonance spaces that they shall give proper resonance values to the sound vibrations produced by the vocal cords. Strength of muscle, accuracy of action and trained control, all to a definite end, are the needs. And the muscles thus employed are extrinsic as well as intrinsic. Delicate harmony of action of the entire vocal musculature is required. Consequently, relatively delicate disturbances even at a distance from the larynx itself, if they occur in the region of the extrinsic musculature, may disarrange the voice. For example, disturbed sensations confuse the speaker or singer, in his attempt to make the required delicate muscular adjustments. Adherent secretion in the pharynx and nasopharynx may seriously impair the vocal control.

Any manner of interference with muscle normality anywhere in the entire physiologic larynx may confuse the vocal procedure. For example, inflammatory edema of the pharynx, nasopharynx, base of tongue, or tonsils, by invading the muscle structure or by pressure on muscle, may serve to disarrange the physiologic laryngeal action.

SUMMARY AND CONCLUSIONS

1. The physiologic larynx includes all muscles, extrinsic as well as intrinsic, on whose movement vocal cord action depends.

2. The laryngeal box, the hyoid and the base of the tongue are closely involved in all vocal action.

3. The base of the tongue region especially is concerned not only with laryngeal action, but also, at the same time, with the shaping of reasonance spaces.

4. This complete complicated musculature has for its purposes (1) the production of endless differences in the manner of vibration of the vocal cords, and (2) the shaping of accurate resonance spaces for the reenforcement of vibrations produced in the larynx.

5. The action of the extrinsic musculature is discernible to an important degree by palpation of the thyrohyoid region.

6. Diagnosis of aphonia from cerebral causes is readily made by such palpation.

7. In the habit-produced falsetto voice, the high tension voice resulting from emotional causes, and in dysphonia spastica, a knowledge of the external musculature is important from both a diagnostic and therapeutic standpoint.

8. Physiologic normality of the voice, and especially of the artistic voice, is dependent on normally acting and cooperating individual muscles within the entire physiologic laryngeal mechanism, and abnormality of voice may result from disturbed sensation or disturbed action of muscles anywhere within this territory.

104 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR. CHARLES G STIVERS, Los Angeles It is time to correlate and coordinate all of the scattered knowledge on the vocal functions into a more cohesive whole, that investigators may know where to look for the latest advances and enjoy that moral support which is essential to all workers in the field of human betterment The need for voice specialists is being expressed by our own members and by the laity—singers, actors, teachers of vocal expression and others, who feel from sad and costly experience with so called "vocal professors" and near-specialists, the need for the adequately trained voice specialist I recently heard a prominent oto-laryngologist say that the time would come when we would have as accurate an estimate of voice ability as is now possible in estimating the loss of hearing and to do so calls for a standard of sound The treatment of the falsetto voice of puberty resolves itself into a reconstruction in the patient's mind of his conception of how his voice should be produced It is really a psychologic approach and it affects a readjustment in the patient's mind, so that his voice becomes placed where it should be in the adult register

DR. LOUIS K GUGGENHEIM, St Louis I should like to ask Dr Kenyon just how he differentiates central from peripheral involvement by putting his hand on the patient's neck As I understand it he attributes the falsetto voice of puberty to the emotional state occurring at that period I believe it has been definitely proved that the falsetto voice of puberty is the result of definite changes in the tissues of the larynx chief among which changes is an edema This edema does not permit the full vibration of the cords but merely the vibration of the edge of the cords

DR JACQUES HOLINGER Chicago There is an answer to Dr Guggenheim as to the central cause of the difficulty of swallowing In bulbar paralysis the only symptom is difficulty in swallowing and, maybe, of phonation This may be recognized by watching the larynx during the act of swallowing or phonation or by putting a finger on it The larynx moves very little or not at all in cases of paralysis You have practically a diagnosis at first hand Bulbar paralysis in old people is not very rare, but I could not find in any textbooks that epidemic cerebrospinal meningitis in children should start with bulbar paralysis Permit me to give you a history I was called to see a girl of 11 who had been sick four days A brother 9 years old had been sick for several weeks with a cold' and was just recovering No diagnosis was made The girl talked indistinctly and had some difficulty in swallowing but sat up in bed and played She had an anxious expression and her temperature was 100 F I asked the child to phonate placing my finger on her throat She had a peculiar, monotonous voice In this, as also in swallowing some water, the larynx was not raised The water went into the larynx and had to be coughed up I suggested a lumbar puncture The suspicion of cerebrospinal meningitis was confirmed Flexner's serum was given but three days later she became unconscious and died I repeat that, at the time I first saw her there was no other symptom except the difficulty in swallowing and phonation It was very apropos that Dr Kenyon took this occasion to draw attention to this whole complex of throat symptoms They are not very frequent but when they are observed, they always indicate some serious central lesion They are very easily overlooked or misinterpreted

DR DENNIS J MCDONALD, New York I should like the author in closing to stress particularly the falsetto voice We all know there is a maldevelopment of the larynx which produces a thinning of the voice There is also a condition in the female in which the voice runs from D above the line a whole octave treatment for which by a great many of our teachers practically ruins the voice Many of these cases, I think are due to strain

DR ELMER L KENYON, Chicago That there can be no organic changes in the structure of the larynx at the time of treatment in most of these cases of high pitch maintained after puberty is perfectly clear, because under training treatment which is adequate, a voice high and strained comes to normal pitch and quality very rapidly I have no doubt there are exceptions, cases in which structural changes in the larynx have had some influence in bringing about an erroneous habit of producing a high pitch Indeed, a considerable portion of such children have had persistent "colds" during the puberty period, when the voice should have been changing The child whose voice is being trained for a singing voice and who is not taught at puberty that the voice must change in pitch and quality may struggle to maintain the childish vocal characteristics until a wrong habit has been formed Answering Dr Guggenheim's question as to the technic of the determination of the aphonic voice by palpation it is extremely simple if one only possesses a clear knowledge of how these extrinsic laryngeal structures act under palpation in the normal person He must know by palpation the manner of action and especially the vigor of muscular effort required to produce the normal (*a*) loud and the (*b*) whispered voice The loud voice requires muscular vigor of action causing vibration, the whispered voice clearly requires less vigor and less definiteness of muscular action The pathologic aphonic voice is apparently nothing else than the normal whispered voice substituted for the loud voice These differentiations are easily determined by one who studies the action of the extrinsic musculature under palpation As to Dr Stiver's suggestion that the falsetto voice is basically a matter of psychology, I perfectly agree Treatment is a matter of changing the person's attitude of mind with reference to his voice, it is a matter of teaching him that he handles his voice wrongly, and teaching him how he must handle it The use of this knowledge of the manner in which the extrinsic musculature acts under normal and abnormal conditions is an important detail in enlightening the person with the falsetto voice with respect to the fact that his attitude toward his voice production is wrong

---

OTALGIA AND MASTOIDALGIA NOT INDICATIONS FOR OPERATION ON THE MASTOID PROCESS

REPORT OF THREE CASES *

HAROLD I LILLIE, M D
ROCHESTER, MINN

Otalgia and mastoidalgia, pain in the ear and in the mastoid region, referred in origin and not due to inflammation or new growths, have been encountered in our practice in cases in which operation on the mastoid had been either advised or performed It was quite apparent that the results, so far as relief of the patients' discomfort was concerned, had not come up to their expectations

The conditions causing this referred type of pain do not appear to be generally understood Wilson says, "In the ear, with its nerve supply from many sources, pain not only suggests the region particularly involved in the inflammatory process, but also makes a constant demand upon the physician to deal with referred pain and to interpret its significance" A careful examination of the mechanism of the ear with a head mirror and reflected light will eliminate the idea that inflammation causes the pain in the ear and mastoid, particularly if adjunct information is derived from a careful study of stereoroentgenograms of the mastoid, and from laboratory examinations, including the leukocyte count, and so forth

* From the Section on Otolaryngology and Rhinology Mayo Clinic
* Read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

It is quite true that the descriptions of otalgia and mastoidalgia in textbooks leave much to be desired A few paragraphs (not chapters), deal very sparingly, in well chosen words, with a subject worthy of much greater detail, a knowledge of which would be of great benefit to physicians and patients For those interested in a careful, detailed study of the sensory nervous mechanism of the ear and mastoid, Wilson's comprehensive article,[1] "Pain in the Ear and Its Diagnostic Significance," will be of interest Wilson says that, in the majority of cases, the pain is referred along the third division of the fifth nerve, less often along the second, and rarely along the first, that the most common seat is in the auriculotemporal nerve of the first division, and that, at times, the pain is referred to a posterior area, where no difficulty is found in associating it with the great auricular nerve

Recently, Sluder[2] has described the painful syndromes associated with disturbance of the sphenopalatine ganglion He deserves great credit for calling our attention to this syndrome, and, as a result, we have encountered fewer cases of this type in which the diagnosis cannot be made I have no doubt that the syndrome exists in his classic description I have observed it in several cases, but my observation has led me to believe it is not necessary that the entire syndrome, as described in the textbook, should be present before the origin of the pain may be diagnosed Frazier[3] has made a comprehensive classification of facial neuralgia It is probable that the type of painful syndrome under discussion would be classified in his fourth, or miscellaneous group, or possibly in his fifth group, in which are the cases of psychoneurosis or psychalgia

The three cases I shall report did not present the complete lower-half headache syndrome, and no direct causal factor for the discomfort was discernible, although careful investigation of the usual causes of reflex pain in the ear was made and each was eliminated

REPORT OF CASES

Case 1.—Miss M S, aged 17, was referred to the ear, nose and throat section of the Mayo Clinic in March, 1921, complaining of pain in the right ear and mastoid The trouble began six years before with severe pain in the right ear, without fever She was taken to a hospital, where a mastoid operation was performed within two hours of onset There was no discharge from the ear or mastoid, and the operative wound healed promptly Pain and tenderness, definitely worse every three or four months, had persisted during exacerbation, all the symptoms appeared worse at night Further operation on the mastoid and removal of the appendix had been advised to relieve the condition The tonsils had been removed

Examination of the ear, nose and throat was negative The right tympanic membrane was denser than the left, but the function of both ears was quite normal The right mastoid tip was tender Roentgenograms revealed no particular evidence of inflammation Roentgenograms of the teeth revealed that the third molars were unerupted, but not impacted The general physical examination and the neurologic examination were negative, but a diagnosis of migraine was made

The sphenopalatine ganglion region was cocainized, and the patient was immediately relieved The change in her facial expression was gratifying Subsequently, on several occasions phenol (carbolic acid) in liquid petrolatum was used in the epipharynx, and the patient remained free from the discomfort

Case 2.—Miss L B, aged 21, came to the Mayo Clinic in February, 1921, complaining of pain in the right ear and mastoid The trouble had begun in August, 1920 There had been no discharge Paracentesis had been performed, and the patient had been relieved of the pain for several weeks This procedure had been repeated In December 1920, the pain became so severe that sleep was disturbed Operation on the mastoid had been contemplated, but because there had been no fever and no increase in leukocytes it was delayed From the patient's friends, it was learned that she had been very precocious in her school work and was regarded as an unusually brilliant student She had never taken part in the social activities enjoyed by other girls

The patient did not present the facies of one who suffered severely The ears, nose and throat were not unusual, the sphenoid ostium on the right could readily be entered The right ear and mastoid showed no signs of inflammation, although the mastoid seemed slightly sensitive to touch The general physical examination was negative except for an adolescent goiter Roentgenograms of the teeth, and the neurologic and eye examinations were negative A diagnosis of migraine was made

The sphenopalatine ganglion region was cocainized and the pain in the ear was definitely relieved for about an hour The application of silver nitrate and phenol in liquid petrolatum seemed to have little effect Finally, March 31, 1921 injection of the sphenopalatine ganglion with alcohol relieved the patient The relief was not immediate, but was complete in a weeks time

The patient returned to the clinic in July, 1921, with a frontal headache, but pain had not returned in the ear and mastoid

Case 3.—Mrs C B V, aged 42, was examined in the Mayo Clinic in August, 1920 and was found to have gallbladder trouble Operation was performed and she was relieved of the symptoms She had had headache since adolescence especially before the menstrual period Her one pregnancy had terminated at three months

Clinical and laboratory investigations proved to be negative except that roentgenograms of the chest revealed an old intralobar pleurisy The patient was seen again in December 1920, and examination revealed no further positive findings

In April, 1921, the patient was referred to the ear, nose and throat section complaining of paroxysmal pain behind the right ear, sometimes also in the throat, for which she had been advised (elsewhere) to have a mastoid operation

Examination revealed apparently negative tonsils and a low grade granular pharyngitis The septum of the nose was deflected, with considerable obstruction on the left side The membrane was undergoing a secondary physiologic atrophy The right side of the nose appeared normal The canals of the ears and tympanic membranes were normal, as was function There was no definite causal factor discovered, although the intranasal and pharyngeal condition may have been contributory

The right sphenopalatine ganglion region was cocainized, and 10 per cent silver nitrate was applied The pain in the ear and mastoid was relieved and there has been no recurrence The patient was instructed with regard to the care of the nasopharynx and this, with the assurance that operative interference was not indicated, may have been a factor in the permanence of the cure

COMMENT

These patients did not present definite etiologic or causal factors for the sphenopalatine syndrome, all could be grouped definitely as nervous individuals, all were relieved of symptoms by treatment directed to the sphenopalatine ganglion Operation on the mastoid region previously had not relieved them of their symptoms I have no explanation for the temporary relief

of the otalgia by paracentesis It seems that, before operation on the mastoid is advised, all conditions which might cause this referred type of discomfort should be investigated

ABSTRACT OF DISCUSSION

DR GREENFIELD SLUDER, St Louis During the past year we have made some observations in the clinic at Washington University as to the control of earache through the nasal ganglion or Meckel's ganglion In a number of observations and experiments we found that a large part of these cases have been controllable with cocain through the nasal ganglion The exception to that would be any condition in which one has reason to believe that cocain is not absorbed In the clinic, and in my own practice, we have found that the pain of otitis media, suppurating under pressure, can be controlled by cocainization of the nasal ganglion We have had some cases in which the landmarks on the drum were more or less obliterated, accompanied by tinnitus in which the pain was stopped and the tinnitus with it by anesthetizing the nasal ganglion Dr Lillie spoke of separate symptoms saying that the entire syndrome is not necessary During the year we have also determined that pain in the lower jaw from the surgical removal of teeth can also be controlled through the nasal ganglion and there is no anatomic explanation of how that may be The paper is interesting as to why the diagnosis of migraine should have been made

DR NORVAL H PIERCE, Chicago We older otologists believe that nonmflammatory otalgia is due to disease of the teeth in 85 per cent of cases, and as I grow older I have no reason for changing that belief In otalgia, of unknown origin we should always have a roentgenogram taken for unerupted teeth Dr Sluder's work in this direction is most interesting but the fact that otalgia can be relieved by cocainization of the region of the sphenopalatine ganglion does not establish the cause of the otalgia It merely blocks the nerve path between the point of irritation and the place to which the pain is referred

DR HARRY L. POLLOCK, Chicago We all have seen cases of impacted molars causing otalgia Three patients were operated on for mastoiditis before they came to us, and we discovered the impacted molars the removal of which relieved the symptoms completely But there are cases in which as far as we are able to determine, there are no underlying pathologic conditions which may cause these symptoms in which the pain is just back of the tip of the mastoid That is always constant in these cases The typical syndrome includes pain over the eye back of the ear in the throat and sometimes in the arm, but in very few cases do we get all these branches of the ganglion at one time The characteristic pain however is just a few centimeters back of the mastoid In many of these cases we find a low grade sphenoiditis causing the pain, and if we clear up the sinuses the trouble and the pain will disappear In many cases the pain comes on postoperatively and we think it is the result of the scar But in those cases in which the application of cocain would relieve the symptoms we are sure to get good results from the injection of the sphenopalatine ganglion They can be reinjected without danger In those cases in which this typical pain back of the ear is present and the application of cocain to the foramen does not relieve it, the injection will not do any good

DR LOUIS K GUGGENHEIM St Louis I shall report a case which may relieve Dr Pierce's doubt and also add a symptom violent throbbing in the ear This patient had no teeth She was 70 years of age and came to me two weeks after an attack of influenza At that time she was perfectly well except for violent pain and throbbing in the left ear This pain was in the region of the tympanic cavity and also in the mastoid and there was marked tenderness on pressure It was difficult to insert a speculum because the canal was so sensitive I found the drum membrane and canal perfectly normal in appearance, the nose and throat were negative For the moment I did not think of the sphenopalatine ganglion I gave the patient a prescription for codein and told her to take a dose every three hours Her daughter gave it to her every hour, without relief She came next day, very much depressed because the pain and throbbing had persisted I then thought of the nasal ganglion and applied 5 per cent cocain in that region Shortly after the speculum could be inserted without pain The patient slept all night without codein and returned the next morning entirely relieved As far as I know she has never had any pain or throbbing since that time

DR WILLIAM B CHAMBERLAIN, Cleveland I performed mastoid operations in two of these cases before Dr Sluder's work on the sphenopalatine ganglion appeared, otherwise I should certainly have tried cocainization In one case, a man aged 30 the roentgenogram was negative, examination of the mastoid and middle ear was negative The pain promptly disappeared after the operation, and he has remained free from pain ever since Needless to say, the mastoid was negative when I opened it The other case was in a girl aged 16 I made all the usual tests, and found the mastoid and the middle ear negative I performed a mastoid operation opened the mastoid thoroughly, and found it absolutely normal The interesting thing about this case is that the mastoid never healed, although it was normal, and of course absolutely aseptic technic was followed She ultimately fell into the hands of a surgeon who, fortunately, was a friend of mine He also tried everything to get this mastoid to heal and finally made a skin graft The mastoid, as far as my knowledge goes, has never healed, and the pain is still persisting I have never had opportunity to try out the cocainization of the sphenopalatine ganglion Another case, in which the pain was localized 2 inches behind the ear, was found to be due to an impacted tooth On removal of the tooth the pain was relieved

DR IVOR G CLARK, Columbus, Ohio In certain of the cases of mastoidalgia without definite pathology the pain in the mastoid is said to be greatly relieved by mastoidectomy I recall a paper by Dr Ayers in which he reported that it relieved several of these patients

DR. HARRY N MAYER, St Louis There is no discussion as far as I am concerned on the point that these headaches can be controlled by cocainization of the sphenopalatine ganglion I should like to suggest that in these cases the diet be looked into carefully to find out what these patients are eating—what they are doing that is not normal It has been my experience that some of these are acidosis cases and sodium bicarbonate and milk of magnesia has helped me effect a cure in some of these lower half headaches that did not respond to the application of cocain to the ganglion

DR. JACQUES HOLINGER, Chicago In several patients suffering from pain in the ear for many weeks we found, after long observations small pimples on the skin and surroundings of the mastoid, which on careful examination proved to be regular herpes zoster efflorescences Herpes zoster in that region is not so very rare, and causes the physician much difficulty of diagnosis and the patient persistent and prolonged pain The membrane and the function are found normal The pain was not increased on deep pressure on the process In two cases there was distinct relief after a mastoid operation These herpes vesicles are easily overlooked Herpes zoster may occur in other regions pertaining to our specialty in addition to the mastoid One patient suffered fearfully in the region of the frontal sinus Intranasal treatments did not help We recognized the real nature of the disease only after the whole head had been shaved, and the patient prepared for a frontal sinus operation according to Killian Large confluent herpetic areas were found sharply limited at the middle line I had treated the same woman two years previous for an acute frontal sinusitis The operation took place eight or ten years ago, she had no complaints since I see her sisters often

DR H I LILLIE, Rochester Minn In answer to Dr Sluder's question about the diagnosis of migraine, that was

made from the neurologist's standpoint, it was not our diagnosis These cases were chosen because none of the usual causes were found in this particular group That is, we had a large group of otalgias and mastoidalgias in which the contributory factors were easily found, but this was another group In that respect I may say that we used every differential diagnosis measure we knew of or could learn of, and we took pains to eliminate all the usual, and some of the unusual, causes for this syndrome

EXPERIENCE WITH CHAULMOOGRA OIL DERIVATIVES IN TREATMENT OF LEPROSY *

HOWARD MORROW, M D
ERNEST L WALKER, S D
AND
HIRAM E MILLER, M D
SAN FRANCISCO

The recent encouraging reports [1] on the treatment of leprosy with the esters of chaulmoogra acid in the Hawaiian Islands induced us to give the leper patients at the San Francisco Hospital the benefits of this remedy The extensive chemotherapeutic studies of Walker and Sweeney [2] at the Hooper Foundation of the University of California furthered our interest in the subject Only by their active cooperation has this work been made possible There have been from twenty to twenty-five patients with leprosy at the San Francisco Hospital for many years When we began treating these cases, we did not anticipate the publication of our findings The results, however, have been so at variance with our expectations and the impression obtained from the literature, that we feel some record should be made of them

EARLY USE OF CHAULMOOGRA OIL

Chaulmoogra oil has long been recognized as the best remedy in the treatment of leprosy Old Buddhist records in India of ten or more centuries ago refer to the improvement in infected persons after eating the raw chaulmoogra seeds In modern times, Dyer,[3] Heiser,[4] Hopkins,[5] Connell [6] and Hollman [7] have reported improvement and even cures due to the administration of the whole oil by mouth over a long period of time Marked gastric disturbances, and the length of time required to obtain results, made this mode of treatment unsatisfactory

To overcome these disadvantages, the mixture of chaulmoogra oil with other substances to make it suitable for subcutaneous or intramuscular injection was attempted The formula proposed by Mercado and Heiser,[7] consisting of chaulmoogra oil, 60 c c , camphorated oil, 60 c c , and resorcin, 4 gm , has been used extensively Heiser [8] reports the cure of twenty-eight patients by the use of this formula Hopkins,[5] McCoy and Hollman,[9] Armellini,[10] Bercovitz,[11] Coghill,[12] Hall,[13] Cadbury,[14] Connell,[6] Hollman and Dean,[1] and others report cures or improvement in cases after the use of this and other combinations

In 1916, Sir Leonard Rogers,[15] in India, reported the preparation of soluble salts of fractions of the fatty acids of chaulmoogra oil and their use intramuscularly and intravenously He made three preparations of the chaulmoogric acids containing fractions of the lower, the medium and the higher melting points The first preparation he called, arbitrarily, sodium gynocardate, the second, sodium hydnocarpate, as it contained a preponderance of hydnocarpic acid, and the third preparation, sodium chaulmoograte, as it contained more chaulmoogric acid than the other preparations The latter preparation formed sodium salts too insoluble for use unless combined with other substances After experimentation, he decided that the sodium hydnocarpate was more active than the sodium gynocardate It was found [16] that sodium hydnocarpate could be prepared more readily and in larger quantities from hydnocarpus oil than from chaulmoogra oil Rogers,[17] Cadbury,[14] Carthew,[18] Muir,[19] Peacock,[20] Connell,[6] Neve,[21] and others report the use of sodium gynocardate subcutaneously and intravenously with very good results Rogers [22] and Muir [23] report even better results with the use of sodium hydnocarpate

Rogers [24] tested the action of other oils with a large content of unsaturated fatty acids, namely, cod liver oil linseed oil Japanese sardine oil, and soya bean oil He found the cod liver oil preparation, called by him sodium morrhuate, to be most effective Advanced cases, treated with it, cleared entirely, and some patients who had ceased to improve with other preparations recovered completely when given sodium morrhuate intramuscularly or intravenously Rogers concluded that the preparation of these different oils may be used to advantage in the treatment of leprosy If a patient ceased to respond to one oil, the preparation of another oil should be substituted

Harper of India reports excellent results in the treatment of leprosy by intravenous injections of a mixture of chaulmoogra oil, sulphuric ether and iodin Muir [26] also reports good results by this method of treatment, but he believes that better results are obtained by the intramuscular or intravenous administration of a formula consisting of ethyl esters of the fatty acids of hydnocarpus wightiana, 1 c c , pure creosote 1 c c , camphor 1 gm , and olive oil, 2 5 c c

At the present time, Muir [26] is giving small doses of the ethyl esters of chaulmoogra acids intravenously at frequent intervals, with encouraging results

The ethyl and other esters of chaulmoogric acids were first prepared by Power and his collaborators in

26 Muir Handbook of Leprosy Cuttack 1921

1904, during their extended investigation[27] of the chemistry of chaulmoogra oil at the Wellcome Chemical Research Laboratories in London from 1904 to 1907.

Notwithstanding the previous preparation of the esters by Power and the ancient use of chaulmoogra oil in leprosy, Ludwig Taub of Elberfeld, Germany, obtained patent rights in Germany in 1909 for the preparation of esters of chaulmoogra acids and their use in therapeutics. This patent right was assigned to a German chemical company, which put the ethyl esters on the market under the trade name of "antileprol." A little later, patent rights were also obtained in Great Britain and the United States. Following the war, and the confiscation of German patent rights, the alien property custodian sold the rights of this patent in the United States to the Winthrop Chemical Company of New York, which is preparing and distributing the ethyl esters of chaulmoogra acids under the trade name of "chaulmestrol."

In 1919, Hollman and Dean[1] reported the preparation and use by intramuscular injection of the ethyl esters of fractions of the fatty acids of chaulmoogra oil for the treatment of leprosy in Hawaii. These acids were separated into fractions by fractional crystallization, and these fractions converted into their ethyl esters. Four fractions in all were used. Groups of cases were treated with each fraction. It was decided that the therapeutic agent in chaulmoogra oil was distributed through all four fractions. This work was later carried on by McDonald and Dean, and is at present under the supervision of Dr. H. E. Hasseltine of the United States Public Health Service.

In 1919, Hollman and Dean[1] reported the treatment of twenty-six cases for less than two years, eight (30 per cent.) becoming bacteriologically negative in this time. In 1920, McDonald[1] reported the paroling of forty-eight cases, and in 1921,[1] ninety-four more cases were added, making a total of 150 cases.

These patients had been treated with weekly injections of the mixed ethyl esters of the acids of chaulmoogra oil, with 2 per cent. of iodin in chemical combination. This was supplemented by capsules containing the fatty acids of chaulmoogra oil with 2.5 per cent. of iodin chemically combined, given by mouth three times a day. In 1921, McDonald[1] reported series of cases treated without iodin and without chaulmoogra oil capsules. He concludes that "the oral administration is by no means necessary," and "the role of the iodin is at most a minor one."

This extended and varied empiric use of chaulmoogra oil and its derivatives in the therapeutics of leprosy was put on a scientific basis by the investigations of Walker and Sweeney,[2] at the Hooper Foundation for Medical Research of the University of California, in 1920. It was demonstrated experimentally that chaulmoogra oil contains substances having a high bactericidal activity in vitro. This bactericidal activity was found to reside in the fatty acids of the chaulmoogric series, and to be a function of the carbon ring structure which is peculiar to the chaulmoogric acids. The bactericidal action of these cyclic fatty acids was shown to be specific against the acid-fast groups of bacteria, and to be inactive toward all other bacteria. Furthermore, it was demonstrated that other unsaturated fatty acids, notwithstanding the therapeutic claims of Rogers and his colleagues, did not possess the specific bactericidal activity of the chaulmoogric acids. From the results of this experimental investigation, it was concluded that the empiric use of chaulmoogra oil and its derivatives in leprosy was justified, and that its therapeutic effect was due to the bactericidal action of the chaulmoogric acids on *Bacillus lepræ*.

TREATMENT OF LEPERS AT THE SAN FRANCISCO HOSPITAL

In August, 1920, we began treatment of the lepers at the San Francisco Hospital, and they were under treatment up to March, 1922, when they were transferred to the national leprosarium at Carville, La.

Of a total of twenty-one cases, there were ten of the nodular type, six of the maculo-anesthetic type, and five of the mixed type. One had shown manifestations of the disease for two months, one for thirteen years, and the others for periods intermediate between these two extremes, the average duration of the disease was four and one-half years. Most of the cases were far advanced. The average period of isolation before beginning treatment was three years.

SUMMARY OF CASES TREATED

Case	Name	Age	Years	Type of Disease	Duration	Severity	Duration Treatment	Average Dose Cc	Condition
1	F. C.	22		Nodular	6 mo.	Moderate	3 mo.	3	Unimproved
2	W. H.	27		Nodular	5½ yr.	Moderate	3 mo.	3	Unimproved
3	L. C.	28		Mixed	5½ yr.	Moderate	2 mo.	3	Unimproved
4	T.	41		Nodular	6 yr.	Advanced	10 mo.	3	Unimproved
5	A. A.	34		Nodular	1 yr.	Moderate	3 mo.	3	Slight imp.
6	L. Y.	27		Maculo-anesthetic	3½ yr.	Moderate	5 mo.	3	Unimproved
7	M.	24		Mixed	3 yr.	Moderate	8 mo.	3.5	Slight imp.
8	G. H.	33		Nodular	3 yr.	Moderate	8 mo.	3	Unimproved
9	D.	37		Nodular	10 yr.	Advanced	12 mo.	3	Worse
10	S.	27		Nodular	9 yr.	Advanced	18 mo.	4	Worse
11	W. K.	24		Mixed	2 yr.	Moderate	17 mo.	4	Much imp.
12	Y. S.	45		Nodular	13 yr.	Advanced	9 mo.	3.5	Unimproved
13	T. L.	36		Mixed	4¼ yr.	Moderate	2¼ mo.	3	Unimproved
14	S. A.	53		Nodular	5 yr.	Advanced	13 mo.	3.5	Worse
15	J. F.	15		Mixed	2 yr. +	Advanced	5 mo.	1	Died during treatment unimp.
16	E. L. B.	71		Nodular	12 yr.	Moderate	11 mo.	4	Died pneumonia unimproved
17	F. W.	19		Maculo-anesthetic	3 yr.	Moderate	14 mo.	3.5	Slight imp.
18	G.	22		Maculo-anesthetic	2 mo.	Mild	3 mo.	4	Absconded unimp.
19	J.	29		Maculo-anesthetic	6 mo.	Mild	2½ mo.	3.5	Absconded unimp.
20	F.	4		Maculo-anesthetic	6 mo.	Mild	8 mo.	4	Unimproved
21	M.	40		Maculo-anesthetic	2 yr.	Moderate	4 mo.	3.5	Much imp.

We employed chiefly the ethyl esters of the total fatty acids of chaulmoogra oil in our treatment. The injections were made intragluteally at weekly intervals, and the dosage was varied according to the weight of the patient and the amount of local and constitutional reaction after the preceding injection. The injections were not supplemented by chaulmoogra oil orally, or by the combination of iodin with the drug.

Laboratory investigations of the chemotherapeutics of chaulmoogra oil and its derivatives, which are being conducted by one of us simultaneously with the treatment of these patients, disclosed that two other esters, the butyl and propyl esters, produced much less local reaction and pain than the ethyl esters or any of a large series of derivatives prepared and tested. Therefore, these two new esters were substituted for the ethyl ester in the later treatment of our patients, and two lepers were treated exclusively with these esters. The clinical results confirmed the relative absence of local reaction obtained in the animal tests, and the

therapeutic action appeared to be as good as that obtained with the ethyl esters

These twenty-one patients were under treatment for a period of from three to eighteen months, with an average of eight months Of these patients, a boy, aged 15 years, with advanced leprosy, died of the disease, one man, aged 71, died of pneumonia-leprosy

Fig 1 (Case 8)—No improvement after eight months treatment

unimproved, three patients in advanced stages became definitely worse, nine showed no improvement, two patients with cases of moderate severity were markedly improved, three with cases of moderate severity were slightly improved, and two patients with the disease in an early stage absconded after three months' treatment

None of these patients became bacteriologically negative during treatment but the nasal discharge in one case (Case 11) became negative after more than a year of treatment The accompanying table, case reports and reproductions of photographs illustrate the results obtained

TREATMENT AT KALIHI AND AT MOLOKAI

In consequence of the slow progress of most of these cases after treatment for fifteen months, it was decided to check up our results by a personal study of the treatment of lepers with the ethyl esters of chaulmoogric acids in the Hawaiian Islands During December, 1921, one of us had the opportunity to see all the patients at Kalihi Hospital, Honolulu, and practically all the patients at the Molokai Leper Settlement

There are 176 patients with lepra at Kalihi under the supervision of Dr H E Hasseltine of the United States Public Health Service These patients present all types of leprosy, from the earliest forms of maculoanesthetic to advanced nodular On account of all the very early cases of lepra in the Territory of Hawaii being segregated in Kalihi, that hospital is an ideal place for experimentation with the derivatives of chaulmoogra oil

The various preparations used in treatment are made at the University of Hawaii under the supervision of Dr A L Dean At present, both at Kalihi and at Molokai, the preparations are used without the addition of iodin The injections are given once a week, and until recently all injections were given into the buttock Since the early part of January, 1922, Dr Hasseltine has been giving a few patients small doses of the ethyl esters intravenously every few days The latter method has the advantage of being painless

Between 1918 and July, 1921, 150 patients were paroled from Kalihi, of this number, ten at least have died, a few have gone to other parts of the islands, and twenty (8 per cent) have returned to Kalihi for further treatment as the result of recurrence of active symptoms of leprosy It is likely that more of the paroled patients will show activity of the disease and will need further treatment

The present system of paroling patients and giving them weekly injections of the ethyl esters for a further period of two years is a good one It allows the patients to work, and with the continued medication there will be fewer recurrences, and many more patients are likely to be permanently cured

During the six months previous to January, 1922, there were but six patients paroled This small number of paroles indicates that the present authorities are using greater caution to prevent the discharge of arrested cases which are later liable to show exacerbations of leprosy There are many patients with an advanced stage of leprosy at Kalihi, probably fifty of whom are incurable with our present method of treatment, and many of these should be sent to Molokai

The settlement of Molokai contains 452 patients, and during 1921 more than 300 received treatment with the ethyl esters As no patients with leprosy have been sent to Molokai since 1919, it is quite evident that very few early cases are to be seen there, and of the 300 receiving treatment, few, if any, show indications of an early parole Dr William Goodhue, the physician in charge of Molokai Settlement, is conscientious in giving the injections, and hopes to see many of the milder cases cured

Fig 2 (Case 9)—Lesions more extensive after twelve months treatment

From conversation with Dr Heiser, Dr Trotter and many others who have had extensive experience in the treatment of leprosy, it seems to be the unanimous opinion that the present treatment with the esters is by far the best of any chaulmoogra oil treatments so far advanced From bacteriologic studies and from clinical symptoms, it seems probable that the present system of treatment will cure the early cases, especially in young subjects The advanced cases certainly improve in time, and it is possible that many of these will be cured after years of treatment Some of the advanced cases show little or no improvement after many months of treatment, and a very small percentage seem to do poorly under treatment

In our cases of leprosy treated in San Francisco, the discouraging results are undoubtedly due to the age

of many of the patients and the advanced stage of leprosy in most of them In the few early cases we have treated, we are satisfied that the present remedy is of great value, and from statistics gathered we are also of the opinion that the injections must be kept up for at least three years in the milder cases and much longer in the advanced ones

Fig 3 (Case 10) —Appearance of patient before treatment

Fig 4 (Case 10) —After eighteen months treatment lesions somewhat larger

Isolation of all advanced cases of leprosy in one leprosarium in Louisiana is an excellent plan Under government control and supervision these patients will receive much better treatment than when they were scattered in isolated county hospitals throughout the United States We shall watch with much interest the results of treatment in this national leprosarium, and particularly the effect of further treatment in our individual cases

REPORT OF CASES

CASE 1—F C, a man, aged 22 born in China, who had leprosy of the nodular type, of six months' duration, was treated three months with an average dosage of 3 c c There were large nodules on the brow and many small nodules on the cheeks, neck, chin and ears There was marked tumefaction of the lobes of the ears The trunk was normal except for a few pigmented macular areas on the back There were a few similar areas on the forearms and arms, and many miliary semiconfluent nodular areas around the wrists Tumefaction and pigmentation of the hands were well marked There was no muscle atrophy Compulsory treatment was discontinued after three months The leprosy was unimproved

CASE 2—W H, a man, aged 27 born in Canton, China, had leprosy of the nodular type, of five and one-half years' duration Treatment was given for three months with an average dosage of 3 c c There were alopecia and tumefaction of the brows, semiconfluent and confluent nodules on the nose cheeks, chin and ears, diffuse, ill-defined macular mottling over the shoulders, arms and forearms, and tumefaction of the backs of the hands There was no muscle atrophy or sensory changes Compulsory treatment was discontinued after three months The leprosy was unimproved

CASE 3—L C, a man, aged 28, born in China, had leprosy of the mixed type of five and one-half years duration The symptoms began six months before entrance The patient was under treatment for a period of two months, with an average dosage of 3 c c There was diffuse but not marked thickening of the forehead, brows nose and cheeks The ears were enlarged, especially in the lobes There was a geographic macular eruption on the neck, a coin-sized, well defined macular eruption on the trunk, anterior and posterior, diffuse macular areas on the arms and forearms multiple miliary nodules on the wrists and tumefaction of the hands a diffuse, leprous thickening of the right palm The ulnar nerves were moderately enlarged, there was thenar and hypothenar atrophy, especially of the right hand There were confluent nodules over the right elbow tip simulating xanthoma There were geographic areas on each thigh and nodules on the right buttocks The patient took treatment under compulsion, and discontinued it after two months No improvement was noted

CASE 4—T, a man, aged 41, born in Greece, had leprosy of the nodular type of five years' duration The patient was under treatment for a period of ten months The average dosage was 3 c c each week There was worm eaten alopecia of the scalp of six years' duration, simulating syphilis The eyes were normal, the trunk, thighs and arms clear, the cheeks shiny and red, with many telangiectases and comedones Small nodules and stains were scattered over the face The brows and lashes were gone The ears were enlarged and wrinkled The hands and forearms were nodular There was passive congestion in the hands, the normal lines of the palms were accentuated On the legs, around the knees, were deep, dark scars There were ulcers on each calf There were nodules and hyperkeratosis of the soles The condition in March, 1922, was more advanced

CASE 5—A A, a man, aged 34, born in India, had leprosy of the nodular type, of one year's duration Treatment was given for three months The average dosage was 3 c c There was alopecia of the brows There was thickening with scattered small nodules over the face, cheeks and chin The nose was broadened and flattened The trunk was practically clear There was marked tumefaction of the hands and feet, and considerable ulceration and secondary infection on the feet In March, 1922, all the areas were slightly improved The patient's general health was improved

Fig 5 (Case 10) —Back of patient before treatment

CASE 6—L Y, a man, aged 27, a Chinese had leprosy of the maculo-anesthetic type, of three and one-half years' duration

The patient was under treatment for a period of five months The average dosage was 3 c c The brows, nose and ears were normal There were confluent and diffuse macules on the face and neck A few chicken-egg sized anesthetic rings were noted on the chest The hands were distinctly claw-shaped, and all the muscles were atrophied The arms and thighs were covered with diffuse anesthetic, geographic areas Compulsory treatment was discontinued after five months, with the leprosy unimproved

CASE 7—M, a man, aged 24, born in Hawaii with leprosy of the mixed type, of three years' duration, was given treatment eight months The average dosage was 3 5 c c There were about a dozen discrete and comparatively flat nodules on the forehead, cheeks and chin confluent on the right cheek There was faint tumefaction of the ears There was a diffuse, confluent and semiconfluent macular eruption on the trunk and thighs Tumefaction was noted on the backs of both hands A few small nodules were located on the wrists and forearms There was no disturbed sensation or muscular atrophy Compulsory treatment was discontinued after eight months The nodules on the face were smaller The macular areas on the body were less distinct

CASE 8—G H, a man, aged 33, a Japanese, with leprosy of the nodular type, of three years' duration, received treatment for eight months The average dosage was 3 c c There were about two dozen small, flat nodules on the cheeks, lips and chin The ears were large, nodular and pendulous There was a faint, miliary, papular rash over the trunk and thighs There was tumefaction over the back of the hands The palms were dry, the normal lines increased After eight months' treatment, the patient complained of general malaise and severe pains all over the body a few hours after each injection The injections were discontinued The leprosy was unimproved

CASE 9—D, a man aged 37, an American, with leprosy of the nodular type, of ten years' duration, was given treatment for twelve months The average dosage was 3 c c There were discrete and confluent nodules over the entire face The nose and ears were ulcerated There was total alopecia of the brows The patient was blind in both eyes There was a diffuse, lichenoid, leprous dermatitis from the scapulae to the buttocks A similar condition existed on the buttocks with scattered nodules throughout There were crenated skin and lichenoid dermatitis on the thighs A diffuse and marked tumefaction was present on the backs of the hands and fingers In March, 1922, the condition of the lesions was more advanced

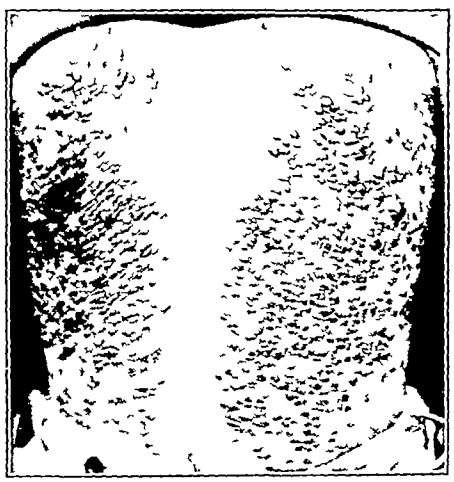

Fig 6 (Case 10)—After eighteen months treatment individual lesions smaller, but much more numerous

CASE 10—S, a man, aged 27, a Portuguese, with leprosy of the nodular type, of five years' duration, was treated eighteen months The average dosage was 4 c c Nodules from the size of a pea to that of a pigeon's egg covered the face Some lesions were almost pendulous A few ill-defined nodules were on the tongue and hard palate There were semipendulous and semiconfluent nodules over the hands and forearms, small nodules over the palms, and scattered pea to lima bean sized semipendulous nodules over the trunk. There was no muscle atrophy In March, 1922, the lesions were somewhat larger and more extensive

Fig 7 (Case 11)—Before treatment

Fig 8 (Case 11)—After seventeen months treatment most of nodules remaining are fibrous

CASE 11—W K a man, aged 24, with leprosy of the mixed type of two years' duration, was treated seventeen months The average dosage was 4 c c Pea-sized nodules were scattered over the forehead, cheeks, nose and ears Some areas were soft and some fibrous A few small nodules were scattered on the forearms There were geographic, cyanotic macules on the trunk, a chronic lichenoid leprid of the thighs, and solid edema of the backs of the hands The ulnar nerves were enlarged There was contracture of the little and ring fingers The nasal secretions contained many lepra bacilli These disappeared after one year's treatment In March, 1922, many nodules had disappeared, leaving pigmentation The remaining nodules were fibrous and apparently inactive

CASE 12—Y S, a man, aged 45 years, a Chinese with leprosy of the nodular type, of thirteen years' duration, was treated nine months The average dosage was 3 5 c c There were confluent, pea-sized, subcutaneous nodules over the entire face The nose was flattened and partially destroyed There were ulcerations on the nose, lips and cheeks There was almost complete alopecia of the brows The skin of the trunk was dry and scaly, with hyperpigmentation over the lower back There was edema of the backs of the hands and the feet Compulsory treatment was discontinued after nine months The leprosy was unimproved

CASE 13—T L, a man, aged 36, a Chinese, with leprosy of the mixed type, of four and one-half years' duration, was treated two and one-half months The average dosage was 3 c c A few faint indistinct nodules were seen on the upper lids There was considerable atrophy of the skin of the face, apparently the result of the absorption of leprous lesions Small cutaneous and subcutaneous nodules were grouped on both forearms There were pigmentation and crenated skin on the backs of the hands and contracture and atrophy of all the fingers on the right hand associated with marked anesthesia There was very little contracture or atrophy of the left hand The condition, after two and one-half months of compulsory treatment, was unimproved

CASE 14—S A a man, aged 53, an American, who had contracted the nodular type of the disease in the Philippines, five years before, was given treatment thirteen months The

average dosage was 3.5 c.c. The forehead was wrinkled and hypertrophied. There were about two dozen small nodules on the cheeks, chin and lips. The left eye had been removed two and one-half years before because of corneal involvement. The entire right eye was blurred, the pupil was irregular from synechiae. The entire body had a faint, wrinkled, pigmented, scaly appearance. The condition of the hands was similar, but more advanced. Very little if any, atrophy was present. In March, 1922, the patient was totally blind. The nodules on the face were larger. The general health of the patient was very poor.

CASE 15.—J. F., a boy, aged 15 years, a German, born in Honolulu, with leprosy of the mixed type, of probably two years' duration, was treated five months. The average dosage was 1 c.c. The patient weighed 50 pounds (22.7 kg.). There was total alopecia of the brows. The nose, ears, lips, cheeks and chin had been partially destroyed by ulcerating nodules. There were dry, faint, mottled and macular areas over the trunk and the extremities. There were tumefaction of the backs of the hands and contracture of the little fingers on both hands. The patient's general condition was much improved after two months' treatment, it became gradually worse however, and he died of the disease after five months' treatment.

CASE 16.—E. L. B., a man, aged 71 years, an American with leprosy of the nodular type of twelve years' duration, was treated eleven months. The average dosage was 4 c.c. The patient was blind in both eyes. The skin on the face was atrophic from absorption of nodules. There was a diffuse, leprous, lichenoid dermatitis over the back, abdomen and the sides of the body, a faint, diffuse, gyrate mottling over the chest and the thighs and crenated skin on the forearms. The backs of the hands were dry, wrinkled, crenated and bluish. There was no muscle atrophy. The patient died of pneumonia after eleven months of treatment, with the leprosy unimproved.

CASE 17.—F. W., a man, aged 19, a Chinese, with leprosy of the maculo-anesthetic type, of three years' duration, was treated fourteen months. The average dosage was 3.5 c.c. There was elephantiasis of the upper and the lower lip. On the face, neck and upper part of the back there were faint, ill-defined, macular areas. The toes and fingers were markedly contracted with considerable atrophy. Both ulnar nerves were definitely enlarged and nodular. The hands and areas on the forearms were anesthetic. In March, 1922, the macular areas were disappearing, otherwise the condition was unchanged.

FIG. 9 (CASE 12).—No improvement after nine months' treatment.

CASE 18.—G., a man, aged 22, born in the Philippines, with leprosy of the nerve type, of two months' duration, was treated for three months. The average dosage was 4 c.c. each week. The right ulnar nerve was about the size of a little finger. The right little finger was contracted. The side of the wrist and palm innervated by the ulnar nerve showed a brownish pigmentation with accentuation of the normal lines. This entire area was anesthetic. The patient absconded after three months' treatment with the leprosy unimproved.

CASE 19.—J., a man, aged 29, born in the Philippines, with leprosy of the nerve type, of six months' duration, was treated two and one-half months. The average dosage was 3.5 c.c. each week. Hyperpigmented and depigmented areas were scattered over the body. Half a dozen dollar sized rings were scattered over the buttocks and the back. There was slight tumefaction of the backs of the hands, with an accentuation of the normal markings on the palms. A similar

FIG. 10 (CASE 15).—Boy, aged 15, died of disease after five months' treatment.

condition prevailed on the soles. There were small ulcers on the great toes. The patient absconded after three and one-half months' treatment, with the leprosy unimproved.

CASE 20.—E., a man, aged 47, an American, with leprosy of the maculo-anesthetic type, had spent some time in Brazil sixteen years before. The duration of the symptoms was six months, the duration of treatment, eight months. The average dosage was 4 c.c. A palm-sized fawn-colored, anesthetic macular area was situated just above the left internal malleolus. After seven months' treatment erythematous macular anesthetic areas appeared on the upper lip and the right cheek. A few months after beginning treatment, the area on the leg was barely visible, at present however, it is about the same as at the time when the patient was first seen. After eight months of treatment, he complained of general malaise with pains in the muscles and joints that were so severe that they prevented him from working. Treatment was discontinued for two months.

CASE 21.—M., a man, aged 45, an Englishman, probably contracted the disease in South Africa. The duration of symptoms was two years. The disease was of the maculo-anesthetic type. He was under treatment for a period of four months. The average dosage was 3.5 c.c. Erythematous, macular areas were situated on the left chin, left temple and left ear. The left posterior lumbar region was covered with an extensive, erythematous, macular eruption. There was a small macular area on the right anterior wrist. The macular areas were all anesthetic to pin pricks, heat and cold. After one month's treatment the areas on the back and wrist became pigmented, and sensation began to return. At present, after four months' treatment, the pigmented areas are fading, and the skin is returning to its normal state. The areas on the face are involuting more slowly. There is general malaise, with pains in the joints and muscles of such severity that the patient is confined to bed for three or four days after each injection. Treatments were discontinued for three or four weeks. The patient was given sodium cacodylate injections during this rest period.

135 Stockton Street

ABSTRACT OF DISCUSSION

DR WILLIAM T CORLETT, Cleveland The paper is fair and comprehensive Its conclusions, however, may be a little too optimistic, but optimism, next to the actual curative agent, is the stimulus that the leper needs Since the parole system was adopted in the Hawaiian Islands in 1918 or 1919, the leper himself has received a new lease of life That the community is more endangered is another question He has felt that it is possible for him to become rid of the malady, which is a valuable curative asset in any disease As to the treatment of leprosy with the ethyl esters So far as I can ascertain, they bring out no beneficial properties not possessed by the old chaulmoogra oil itself—when the patient can take chaulmoogra oil But the crude oil is often irritating to the stomach, and many patients cannot take it. In such instances the intramuscular, or better, the intravenous, administration of the ethyl esters is a decided advantage The separation of the ethyl esters made available in 1904, or soon after, must be, therefore, considered a step in advance A few weeks ago when I left Honolulu, Dr Hasseltine, the marine and public health officer, was giving, when possible, the ethyl esters intravenously, and this to my mind will prove to be the future treatment for leprosy The use of the ethyl esters intramuscularly, into the buttocks, is painful, much more so than the same method of giving mercury Even when patients are willing to submit to it, there are disadvantages I recall two cases in which extensive abscesses followed this procedure, while the introduction into the veins is painless If the ethyl esters can be rendered sufficiently innocuous to be introduced safely into the veins, it would be the best treatment of leprosy so far as relates to the ethyl esters or the newer derivatives of chaulmoogra oil

DR R M WILSON, Korea I have 800 patients with leprosy under my care I have trained our lepers to do their medical work and use the microscope, as well as other laboratory work, and I am enthusiastic about chaulmoogra oil I believe that chaulmoogra oil is as good as the ethyl esters because it contains many things the ethyl esters do not We have been using chaulmoogra oil, 1 per cent, and for six months we have been using the ethyl esters but the ethyl esters have not affected the old cases treated by chaulmoogra oil Either the ethyl esters or chaulmoogra oil in a new case will show quite marked results in six months' time I think that in the cases shown this morning we could hardly hope to see much improvement, because the cases are so advanced The great hope is in the younger cases, particularly the children, who respond more readily We find in some cases that improvement takes place under hypodermic injections before the internal treatment is effective In our institution we have the industrial work pretty well established, these patients do brick and tile work, and they prefer to take the capsules internally and that seems to hold them in check Many cases are not entirely healed, but they are held in check I have 300 patients on the ethyl esters in Peking and 200 on chaulmoogra oil, and hope to report in a year's time which gives the best results These lepers come in literally crawling in the dust, feeling that they are dead dogs, and then when they come to realize that we can do something for them they are the happiest group you can find I am very enthusiastic about the ethyl esters, and believe there is no doubt that we can get splendid results in the early cases

DR I L MCGLASSON, San Antonio, Texas In San Antonio we have about thirty cases of leprosy, not that number under treatment, but that is about the number we have proved This paper is a wonderful article on the class they have attempted to treat, but I believe that the problem in leprosy is the same as in tuberculosis and cancer—there are cases we cannot touch I think that it is unfair to draw conclusions from the old and hopeless cases It is the early case in which we can do the most good I am going to advance another opinion, and that is that many cases are not recognized They occur not in the poorer class but in the better classes, and yet they are lepers The class in which we get the best results, in my experience, consists of early cases, when the patients are in fine shape physically and mentally I think the point is well taken by Dr Corlett as to the time when they will return A certain percentage will recur, which indicates that we have stopped treatment early We have no means of knowing when they can be discharged as cured and when they can stop treatment Whether this is the best treatment or not, we are on the right track to get a treatment which can offer something if we get the cases in time My experience is that in the + and ++ Wassermann reactions that cannot be substantiated clinically, if one will investigate the nose and the skin, one will probably find some evidence of leprosy Let us keep an open mind on this The cases in California were far advanced, and it would take a long time before they could be influenced by the ethyl esters or chaulmoogra oil, but in the early cases I am sure that a great deal can be accomplished, and many patients cured

DR ERNEST D CHIPMAN, San Francisco The cases reported were old, but I know from personal conversation with Dr Morrow that they have taken the cases as they found them and that they thoroughly believe in the efficacy of the treatment in early cases Dr Corlett, and I think Dr Wilson also, expressed the view that a very important feature in leprosy is the moral effect produced by the introduction of a treatment that gives the patients some hope I have had an opportunity of visiting the hospitals in Honolulu twice during the last few years, and have been much impressed with the apparent happiness with which patients faced their hospitalization Whereas in former times they made every effort to conceal the disease, they now come voluntarily for treatment

DR FLOYD STEWART, St Louis I had the pleasure of treating many of these patients with Dr Isadore Dyer of New Orleans Dr Dyer first began using potassium chlorate, sodium salicylate and strychnin He reported a case as a probable cure because all the lesions cleared up The patient was dismissed from the Charity Hospital outclinic, and was not taken to the leper colony At that time it was purely voluntary, there were no laws to transport these people, and this patient, a negro, returned to work, but in about eighteen months he came back for further treatment At that time Dr Dyer took up another treatment, called the "antivenin" treatment He purchased this serum from the Calmette Laboratory at Lille, France, and it gave remarkably good results at first Following this case we had several that showed improvement for a certain length of time, and then retrogressed Dr Dyer discussed the use of the antivenin serum, not on account of the cost, which he had defrayed himself, but because of the poor final results Then he took up this new treatment with chaulmoogra oil He was rather enthusiastic about the results he was obtaining I hope that Dr Morrow's results are encouraging enough for him to persist in treating these cases, and that he will succeed in curing the mild cases at least, for it is quite evident that when physicians and patients are enthusiastic about a remedy, better results will be obtained

DR EDWARD A OLIVER, Chicago We have had about seven of these cases under treatment in the Cook County Hospital and have been very enthusiastic about the ethyl esters Six were of the nodular type and one of the maculo-anesthetic type We first started on chaulmoogra oil, and then when we received the ethyl esters we used them There was no patient who did not improve, but they were only moderately advanced cases One patient was a Serbian, and he improved very rapidly, all of the lesions disappearing One man we have paroled now Every one of these patients improved mentally, physically and in every other way under the ethyl ester treatment

DR. HIRAM E MILLER, San Francisco In presenting this paper we had only hoped to moderate the impression that advanced cases of leprosy were being readily cured by the injection of ethyl esters over a comparatively short length of time However, I would like to emphasize the fact that we feel that early cases in young persons may be cured with the present methods of treatment

PHARYNGEAL INSUFFLATION ANESTHESIA*

ALBERT H MILLER, M D
PROVIDENCE, R I

In any system of ether administration by inhalation, a percentage of ether vapor is added to the tidal respiratory air and is carried to the pulmonary alveoli during inspiration On expiration, a part of the ether vapor is expired and wasted, the proportion of waste depending on the point in the respiratory tract to which the ether vapor has been delivered The points of delivery of the ether vapor in inhalation anesthesia, arranged in order of their efficiency are the bifurcation of the trachea, as in tracheal insufflation, the oropharynx, as in pharyngeal insufflation, and the nasal and oral orifices, as in the usual methods of anesthesia

ADVANTAGES OF PHARYNGEAL INSUFFLATION ANESTHESIA

When compared with the delivery of ether vapor to other points in the respiratory tract, pharyngeal insufflation has manifest advantages The introduction of the pharyngeal tube is a simple matter, takes little time and does not require a deep initial anesthesia After the introduction of the tube, the surgeon has a clear field for operations on the face, head, neck, chest and upper air passages No inhaler nor mask covers the mouth and nose The operation is not hindered by proximity of the anesthetist or of his appliances The constant flow of air into the pharynx provides for the requirements of respiration, and permits covering the face with sheets and towels without interfering with the respiration

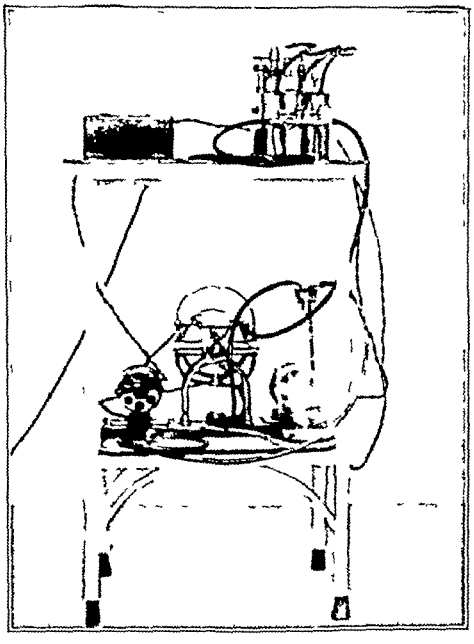

Fig 1—Apparatus for pharyngeal insufflation anesthesia Above rheostat for controlling speed of motor constant temperature ether vaporizer Below motor and air pump bottle connected with suction apparatus

APPARATUS

The essentials for satisfactory pharyngeal insufflation are an apparatus for delivering a current of air, capable of regulation up to 10 liters per minute, a vaporizer which will mix with the air current a constant percentage of ether vapor and which can be perfectly controlled as to the ether vapor percentage delivered, and nasal and oral tubes for delivering the ether vapor air mixture to the orophrayn x

Means for providing the current of air for pharyngeal insufflation are an air pump actuated by an electric motor, the speed of which is controlled by a delicate rheostat, or a tank of compressed air controlled by a reducing valve, or a foot pump If no means for controlling the speed of the electric air pump is provided, the foot pump should be chosen, as the rate of flow of the air can be roughly controlled by the speed at which the foot pump is worked The object of this apparatus is to keep the air in motion and not to produce positive pressure

The mixture of ether vapor and air is formed by injecting liquid ether regularly, in small amounts, into the air current, by atomizing or aspirating liquid ether into the air current, or by passing the air current over the surface of liquid ether in a container In the last of these methods, which is the one most commonly used, the rate of vaporization depends on the temperature of the liquid ether in the container As evaporation goes on, the liquid ether constantly becomes colder, with resulting diminution in the rate of vaporization and in the anesthetic dosage If the ether container is placed in a warm water bath of uncertain temperature, the result is uncertain, and may be either an overdose or an underdose of the anesthetic

The constant temperature ether vaporizer is designed to overcome the uncertainty as to ether dosage resulting from variations in temperature By means of an electric heater and thermostat, the liquid ether is kept at a constant temperature of 32 C (90 F) With a constant current of air passing across the surface of the ether, the percentage of ether vapor with air will also be constant An arrangement of valves attached to the vaporizer allows the entire current of air, or any fraction of the entire amount, to pass over the liquid ether, the remainder flowing directly through a by-pass By varying the percentage of the air current which is allowed to pass through the ether chamber, any strength of ether vapor in air, from zero to the capacity of the apparatus, may be obtained, and will be delivered constantly as long as the air current is maintained, the position of the valves is unaltered and ether remains in the container

The diameter of the ether container is 3 inches (7 5 cm), and the evaporating surface measures 45 6 square centimeters

With the thermostat set for 32 C (90 F), and the electric air pump delivering 5 13 liters of air per minute, the ether vapor strength is 60 per cent by weight and 29 per cent by volume, or 220 millimeters ether vapor tension The method of computation follows

Period, ten minutes

Volume of air, 51 3 liters, by direct measurement

One liter of air at room temperature, 20 C (68 F) weighs 1 205 gm Weight of air $51\ 3 \times 1\ 205 = 62\ 8165$ gm

Weight of ether vaporized, 38 27115 gm, by subtraction from total amount

Percentage of ether to air by weight, $38\ 27115 - 62\ 8165 = 60$

Formula for reducing percentage by weight to percentage by volume $X = \frac{32\ P}{32 + 83(1\ 00 - P)}$, when X is the percentage by volume expressed as a decimal, and P is the percentage by weight expressed as a decimal

Substituting 0 60 for P in this equation

$$X = \frac{32 \times 0\ 60}{32 + 83(1\ 00 - 0\ 60)} = 0\ 29$$

Twenty-nine per cent of 760 = 220, the ether vapor tension in millimeters of mercury

* Read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

The nasal tube is curved to fit the cheek, with the tip bent to enter the nasal orifice To the tip is attached a rubber tube about 5 inches (12 5 cm) long and one-quarter inch (6 mm) in diameter The oral tube is bent to fit the cheek, with the tip bent to enter the mouth, and has a similar rubber tube attached Since a single tube is sufficient, there is no advantage in the

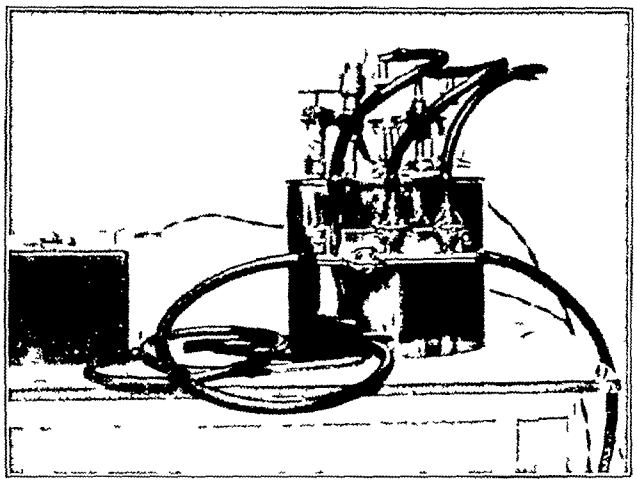

Fig 2—Constant temperature ether vaporizer water bath kept at a constant temperature by an electric heater and thermostat Woulfe bottle partly filled with ether valves mounted on water bath inlet to right outlet to left When all valves are in horizontal position as shown the air current passes through the by pass and carries no ether vapor This starting position cannot readily be mistaken

use of double tubes The rubber tip of either the nasal or oral tube reaches to a point in the oropharynx opposite the tonsils

TECHNIC OF ADMINISTRATION

Before the anesthesia is begun, the pump is started and set to deliver a current of air of from 6 to 10 liters per minute If the amount of air delivered is not sufficient to provide for the entire respiratory need, a more concentrated ether vapor will be required to compensate for the dilution of the mixture Until the introduction of the nasal or oral tube, the entire air current passes through the by-pass and carries no ether vapor The initial anesthesia is secured in the customary manner and need be only deep enough to permit the introduction of the tube without resistance from the patient The tube is lubricated and is slipped gently into the nostril or into the mouth over the tongue The tube may be held in place by a strip of adhesive plaster across the cheek Whether the nasal or oral tube shall be chosen depends on the nature of the operation to be performed For operations on the nose or nasal passages, the oral tube is chosen In most other cases, the nasal tube is used, as it does not readily become dislodged For the tonsil and adenoid operation, the nasal tube is introduced, and it is removed when the adenoid operation is to be commenced

After the tube has been introduced, a steadily increasing percentage of the air current is made to pass through the ether chamber until the entire current is passing over the ether The depth of anesthesia is controlled by regulating, with the valves, the percentage of the air current which is allowed to pass through the ether chamber and not through the by-pass After studying the patient's reaction to the anesthetic for a few minutes, the anesthetist may move away from the patient He can judge the depth of anesthesia by the character of the respiration, the state of muscular relaxation, the movements of the extremities, especially of the fingers and toes, and the respiratory reaction on suddenly slightly increasing the ether vapor percentage As the anesthetist may not be able to control the jaw without interfering with the operation, an artificial air way is introduced, if indicated

In draping the patient for the operation, interference with the respiration from sheets or towels may be neglected, as the constant current of air entering the pharynx is sufficient for the respiratory need The operation proceeds without interference due to proximity of the anesthetist or his appliances to the operative field The principal care of the anesthetist, aside from maintaining the proper depth of anesthesia, is to see that respiration is not mechanically interfered with by the surgeon or assistant

OBJECTIONS TO PHARYNGEAL INSUFFLATION ANESTHESIA

Theoretical objections which are raised to this form of anesthesia are based on an increased pressure in the pharynx, and the danger of postoperative pulmonary complications due to this increased pressure The first of these objections can be readily answered by connecting a manometer in series with the tube which joins the vaporizer to the nasal or oral tube While the apparatus is in use, the manometer registers no pressure whatever except when a lightly anesthetized patient attempts to swallow, when a pressure of 10 or 12 millimeters is momentarily indicated One having a knowledge of the structure of the pharynx would be able to foretell this result As the pharynx has five principal openings, it would not be sensible to suppose that an air current entering one of these openings could increase the intrapharyngeal pressure while the four other orifices remained open

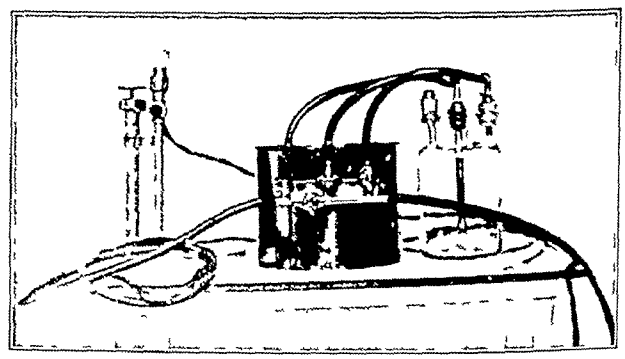

Fig 3—Constant temperature ether vaporizer from left to right electric heater and thermostat water bath Woulfe bottle inlet to right outlet to left tube in center opening dips into ether When first and third valves mounted on water bath are in the vertical position all of the air current passes through the ether container When the valve to the left is in the horizontal position and the one on the right is vertical as shown less than half of the air current passes through the container As the left valve is turned from this position to vertical the percentage of ether vapor is increased With the left and central valves vertical and the right horizontal the air current bubbles through the liquid ether and the ether percentage is considerably increased

To determine the effect of pharyngeal insufflation in producing postoperative pulmonary complications, it is necessary to compare the results in this form of anesthesia with the results of other methods For this purpose, I have tabulated 1,000 recent consecutive personal cases These 1,000 operations were followed by twelve pulmonary complications, one case of pulmonary

embolism resulting fatally The percentage of pulmonary complications is 1 2 and the mortality from these complications is 0 1 per cent Pharyngeal insufflation was used in 188 of these 1,000 cases, with two postoperative pulmonary complications Both of these patients developed a cough without fever, and both recovered The percentage of pulmonary complications in these 188 cases was 1 06, with no mortality This experience is corroborated by the records of institutions which have used pharyngeal insufflation extensively, without any increase in the proportion of pulmonary complications It is probable that, so far as the anesthetic has any effect in the production of pulmonary complications, these unfortunate results depend on the depth of anesthesia rather than on the method employed, and that, following a light degree of anesthesia, these complications rarely occur

CASES SUITABLE FOR PHARYNGEAL INSUFFLATION

In the 1,000 cases tabulated, pharyngeal insufflation was employed 188 times or in 27 per cent The accompanying table indicates the nature of the operations and the results

NATURE OF OPERATIONS AND RESULTS

Operation	Number of Cases	Results *
Tonsil and adenoid	112	
Goiter	16	Two died of hyperthyroidism one in ten hours one in three days one developed cough without fever
Nasal septum	11	One developed cough without fever
Breast	9	
Mastoid	8	Two died from meningitis one in six days one in thirty three days
Sinus	4	
Brain	4	
Maxilla	4	
Cervical glands	4	
Kidney	4	
Esophageal diverticulum	2	
Laryngeal tumor	1	
Spinal cord	1	
Tongue	1	
Nose	1	
Ear	1	
Eye	1	
Other operations	4	
Total	188	

* Satisfactory except as noted

CONCLUSIONS

Pharyngeal insufflation anesthesia is chosen for all of the operations in which the ordinary methods interfere with the work of the surgeon In these cases, it is essential to efficient surgical work The apparatus should be carefully chosen and intelligently used Pulmonary complications following the use of pharyngeal insufflation are not due to the method, occurring with no greater frequency than after other forms of anesthesia

131 Waterman Street

ABSTRACT OF DISCUSSION

DR JOSEPH C BECK, Chicago Even if the instrument the author recommends is better, I believe the Beck-Mueller apparatus should not be discarded I find no difficulty of any kind since using the motor-driven apparatus that was perfected by Dr Mueller The only thing I cannot agree with is to have the mouth wide open when the anesthetic is given This anesthesia is not used at all in our clinic since we have adopted synergistic anesthesia There is a combination of ether, olive oil and paraldehyd the subcutaneous injection of morphin, ⅛ grain each hour, probably in combination with a 25 per cent solution of magnesium sulphate This anesthesia serves for all purposes in our line of work, and only in children have we thus far used anything but this rectal anesthesia, because we have not proved it to our satisfaction Dr Herb recommends paregoric instead of morphin My objection to the motor-driven apparatus is the horrible smell of ether through the house, and the irritation which it causes, and then the noise it makes

DR EDWIN MCGINNIS, Chicago I want to ask whether in using this motor-driven apparatus you can grade the amount of ether coming out of the end of the tube The disadvantage of the Beck-Mueller apparatus in laryngeal surgery is that there is too much ether If in this apparatus the control is better, if it will deliver a reduced amount of ether I should say that it would be an advantage

DR ALBERT H MILLER, Providence, R I I would apologize to Dr Beck for not having shown his very good apparatus, but I announced at the first that the forms of apparatus to be shown were selected only as types The new apparatus shown does deliver a regular, measured dosage of ether vapor The dosage can be regulated by varying the percentage of air which is allowed to pass through the ether chamber The maximum capacity of the apparatus is greater than is usually required I think that we have in this apparatus an extremely delicate, scientific sort of instrument which will maintain an exact degree of anesthesia for an indefinite period We have found that in addition to the tonsil and septum operations, cases of goiter, diverticulum of the esophagus, tumor of the larynx, and other difficult cases which are often done under local anesthesia with great discomfort to the patient for lack of such a delicate apparatus can be done perfectly by means of this apparatus and for this reason I wish to introduce it

EXPERIMENTAL STUDIES ON THE ETIOLOGY OF ENCEPHALITIS

REPORT OF FINDINGS IN ONE CASE*

EDWARD C ROSENOW, M D
ROCHESTER, MINN

It has been my privilege to study the etiology of encephalitis during the past three years through the cooperation of Dr Shelden and his associates of the Section on Neurology of the Mayo Clinic From the outset of this study it was considered possible that the disease might be caused by a filtrable virus or by bacteria of more ordinary morphology but with peculiar neurotropic properties The methods employed were such as to test both possibilities Altogether, forty cases, representing different clinical types of the disease, have been studied A large number of animals have been injected, the microscopic study of sections is not yet completed and other details in the mass of experimental data are awaiting final analysis

In order to illustrate in general the scope of the work and the results obtained, I shall report at this time in some detail the findings in one case

Mrs P E aged 53 years, first seen March 25, 1921, complained chiefly of a nervous breakdown, the symptoms of which began in January 1921, when, after a period of hard work and worry she suddenly felt weak and tired, and developed noticeable trembling all over her body This trembling lasted for about a week and from that time on she had been either in bed or sitting in a chair most of the time Her daughter said that her mother had been irrational for some time

At the time of the first examination she was markedly excited She had numerous hallucinations marked anxiety, both motor and psychic restlessness, a rapid pulse, and slight increase in temperature Physical examination revealed badly

* From the Division of Experimental Bacteriology Mayo Foundation
*Read before the Section on Nervous and Mental Diseases at the Seventy Third Annual Session of the American Medical Association, St Louis May, 1922

infected teeth, hyperemic mucous membrane in the nasopharynx, and slightly enlarged heart She could move her legs, although the muscles were very weak Sensations were apparently normal, except for numbness over the dorsum of the left foot The knee jerks were normal The pupillary reflexes and fundi were negative The urine contained a small amount of albumin and pus Examinations of the blood, including the Wassermann reaction, were negative

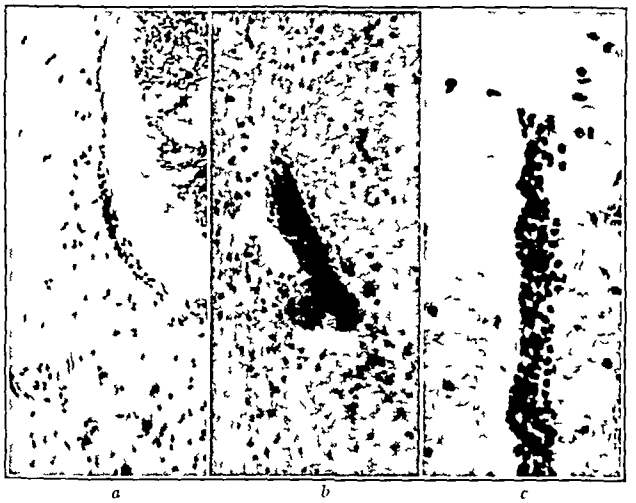

Fig 1 —Localized adventitial and perivascular round cell infiltrations in the base of the brain of the patient hematoxylin and eosin *a* and *b* × 100 *c* × 200

March 28 the patient was admitted to Stanley Hospital where she continued to have hallucinations of hearing and sight She soon became lethargic and stuporous, and developed external ocular palsies and general twitchings of the muscles especially of the lower extremities and the abdominal wall During her illness in the hospital the leukocyte counts were 6,900 and 8,100, the hemoglobin was 75 per cent The Wassermann reactions on the blood and spinal fluid were negative, and the Nonne on the latter was positive The spinal fluid was clear and contained one lymphocyte On the ninth day the pulse became very rapid and irregular, and the temperature rose The patient died rather suddenly in profound coma on the night of the tenth day One injection of the antiencephalitis serum was given shortly before death without effect

Necropsy revealed encephalitis senile atrophy of the ovaries, small cervical polyp, and marked sepsis of upper and lower teeth The convolutions of the brain stood out prominently and were extensively injected On section of one half of the brain a golden raised area measuring 1 5 cm in diameter was found in the region of the pons, otherwise the brain presented no gross abnormalities The abdominal viscera, the lungs and the heart disclosed moderate cloudy swelling, but no other changes

Histologic examination of the kidneys revealed an occasional glomerulus replaced by a hyaline scar, and thickening of Bowman's capsules, with hyaline changes in some of them The walls of the blood vessels were slightly thickened Histologic examination of sections of the brain revealed no noteworthy lesions except those in the basal ganglions A number of sections from these areas revealed moderate perivascular infiltration, localized adventitial round-cell infiltration of the larger blood vessels (Fig 1) areas of hemorrhage, usually around the blood vessels, moderate degeneration of the ganglion cells, and neurophagocytosis (Fig 2) Sections of the golden area, which resembled grossly a resorbing area of hemorrhage, revealed a striking phagocytosis of brownish pigment granules by the nerve ganglion cells (Fig 3) Prolonged search of sections of the base of the brain stained by the Giemsa and Gram-Weigert methods revealed undoubted diplococci varying much in size and shape (Fig 4 *a b, c* and *c'*) In some instances large, swollen diplococci seemed to be breaking into a variable number of small forms (Fig 4 *c*) These were found in the lesions or immediately adjacent to them In sections of the cerebral cortex and medulla, which showed no changes, the demonstration of micro-organisms was not accomplished

Cultures of emulsions of the base of the brain yielded a pure growth of the green-producing streptococcus A similar streptococcus was isolated from the apexes of the infected teeth after death, and from the pyorrhea pockets and the blood during life Cultures from the blood after death yielded a pure growth of the hemolytic streptococcus Cultures from the cerebral cortex the medulla the cervical cord and the spinal fluid were negative

EXPERIMENTS

Injections into animals were made with (1) the sediment of the defibrinated blood obtained during life, (2) the pure culture of hemolytic streptococcus obtained from the blood after death, (3) nasopharyngeal washings in salt solution, (4) filtrates of the nasopharyngeal washings, (5) salt solution suspensions of pus aspirated from pyorrhea pockets, (6) cultures from the apical infection of an incisor removed in a sterile manner at necropsy, (7) emulsions and filtrates of the central nervous system, (8) the spinal fluid, and (9) cultures from a lesion in the base of the brain

The sediment from the defibrinated blood was injected intracerebrally into two rabbits Both remained well The culture from the blood after death which yielded a pure growth of hemolytic streptococcus was injected intracerebrally into three rabbits, two receiving 0 1 c c, and one 0 1 c c of a 1 10 dilution All died of meningitis within twenty four hours and countless numbers of hemolytic streptococci were found in the turbid spinal fluid

A suspension in salt solution of the nasopharyngeal washings was injected intracerebally (0 2 c c) into one rabbit, the animal died within twenty-four hours Necropsy revealed a large area of hemorrhage at the point of injection, hemorrhages between the cerebellum and medulla and slightly turbid spinal fluid The cultures became contaminated and were lost

The filtrate of the nasopharyngeal washings was injected intracerebrally (1 5 c c) into each of two rabbits Both remained well One was chloroformed one week after

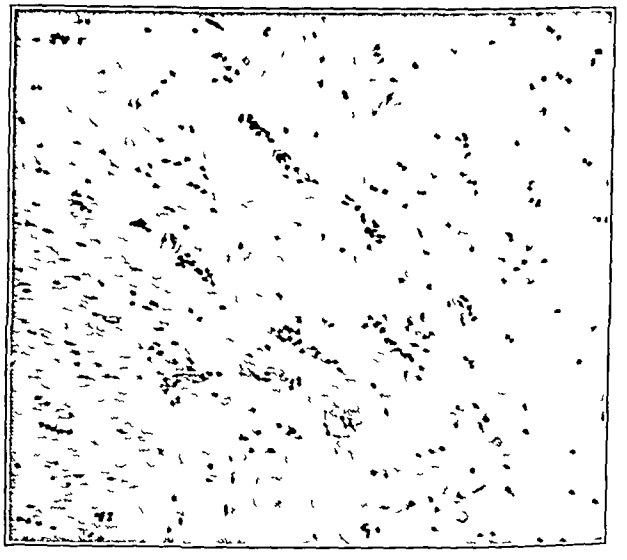

Fig 2 —Collections of round cells and neurophagocytosis in the pons hematoxylin and eosin × 100

inoculation, and the findings in the brain and cord were negative A rabbit inoculated intracerebrally with an emulsion of the brain of this rabbit remained well

A salt solution suspension of the pus from pyorrhea pockets was injected (0 2 c c) into one rabbit The animal became comatose, developed twitchings of muscles and occasional spasms of the abdominal muscles and extremities, and died twenty-four hours after the injection apparently from respiratory failure Cultures from the brain on blood-agar

plates yielded countless numbers of colonies of green-producing streptococci Those from the blood were negative

One tenth cubic centimeter of a subculture of the brain of this rabbit in the tenth generation was injected intravenously into one rabbit, which remained well

The primary culture in glucose-brain broth from the infected incisor, which on plating yielded many colonies of green-producing streptococci and a few colonies of staphylococci,

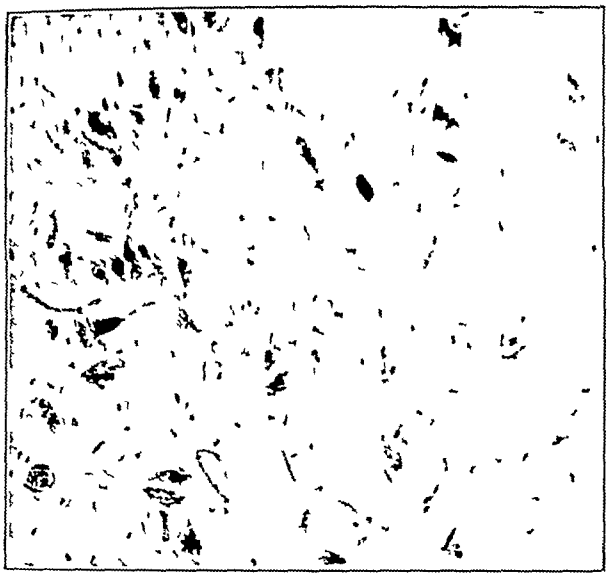

Fig 3—Pigmentation of ganglion cells in lesion showing brownish discoloration hematoxylin and eosin × 100

was injected intracerebrally into two rabbits one receiving 0 1 c c, the other 0 1 c c of a 1 10 dilution Both died within forty eight hours The brain of one yielded a pure culture of the green producing streptococcus, the brain of the other yielded this organism and a few colonies of staphylococci Inoculation from a single colony of the green-producing streptococcus of the fresh growth on a blood-agar plate was made into glucose brain broth This was rapidly transferred, and a five hour culture in the tenth culture generation was used to soak a strip of gauze, with which the nose of one rabbit was packed, and to inject intracerebrally one rabbit (R 2523), with 0 1 c c, of a 1 100 dilution The rabbit whose nose was packed remained well for forty-eight hours, when the pack was removed On the third day it sat quietly in the cage, respirations were increased, it was irritable and tremulous, and disinclined to hop On the fourth day it developed ascending paralysis, from which it died The spinal fluid was turbid the medulla and the cervical cord contained small hemorrhages, the vessels of the cerebrum were congested, but there were no hemorrhages There was no exudate surrounding the olfactory lobes Cultures of the blood were sterile, those from the brain and the spinal cord yielded the streptococcus Sections of the brain showed marked leukocytic infiltration around the vessels of the meninges, and infiltration of the pia over the base of the brain and the cervical cord Gram-positive diplococci were found in the lesions, but not elsewhere The findings in the rabbit injected intracerebrally were as follows

Rabbit 2523, weighing 1,390 gm, was injected, April 13 1921 April 14, at 7 a m it appeared well at noon it seemed well but was somewhat drowsy, and at 2 p m it sat quietly as if half asleep At 9 p m, it still appeared sleepy, and slightly tremulous in hopping April 15, at 7 a m, there was marked tremor of the anterior part of the body, this became worse when the animal hopped At noon it had developed peculiar motions of the head, synchronous with a vertical nystagmus At 7 p m, it sat quietly in the cage, respirations were slow, the left eyelid drooped, and the upper eyelids twitched rhythmically, this was peculiar as the right eyelid moved quickly downward the left moved upward and vice versa The animal responded slowly to stimuli, and when it hopped a coarse tremor and occasional twitchings of the muscles of the anterior part of the body were noted April 16 the animal was undoubtedly better, though it was still sleepy, and ataxic in hopping, the peculiar rhythmic movements of the eyelids had disappeared April 18, the animal was less sleepy and less ataxic April 20, the lethargic symptoms had become worse The animal hopped slowly and stiffly, and only when goaded Response to stimuli was delayed April 21, at 9 a m, it sat as if asleep It could be aroused but responded slowly, and immediately after being prodded it apparently fell asleep in the characteristic attitude, the head held somewhat forward the ears erect and in tension and the eyes half closed At 11 30 a m, the somnolence was marked The animal was photographed sitting up, lying on its side, and on its back, sound asleep in each position (Fig 5) The next day at 6 45 a m, it sat quietly in the cage, apparently fast asleep Slight or moderate stimulation failed to arouse it If it was pushed to one side and lost its balance it would right itself and assume its characteristic position When forced to hop it did so very slowly and immediately went to sleep At 9 30 p m, the condition was unchanged April 28 the animal was undoubtedly less lethargic, it responded more promptly to stimuli, its head tilted to the left April 30 the lethargy had largely disappeared, but the animal held its head markedly to the left May 5, it appeared wide awake, was alert and ate normally The tilting of the head had become more marked so that it was held in an almost horizonal plane There was a tendency to fall to the left May 18 the condition was unchanged May 20, snuffles developed and severe infection of the right eye May 22, the animal was found dead There were no gross lesions in the brain or the cord The nostrils contained mucopus Cultures from the blood and the brain were completely overgrown by a spreading gram negative bacillus Sections of the brain showed several areas of round-cell infiltration in the corpus striatum along the blood vessels (Fig 6), and central portion of the cerebellum near the juncture of the pons There were no lesions in the choroid plexus, meninges, medulla or cervical cord

Approximately a 20 per cent emulsion from the base of the brain and lesion in the pons was injected intracerebrally directly in doses of 1 c c into three rabbits and 1 5 c c into one monkey Two of the rabbits and the monkey

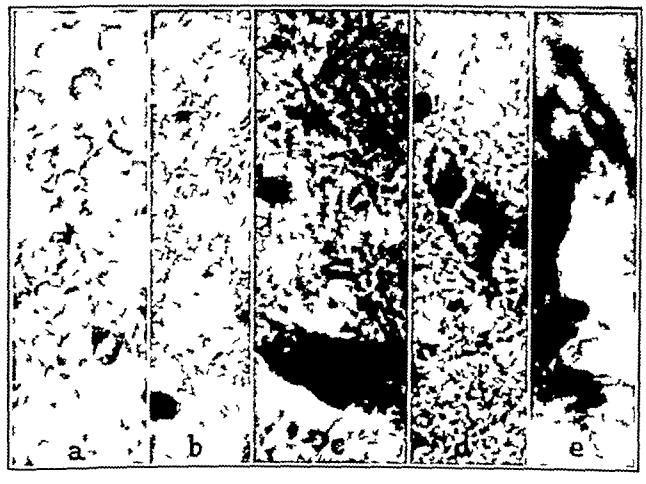

Fig 4—Diplococci in lesions in the basal ganglions *a* area of hemorrhage in the pons Gram Weigert × 1 000) *b* and *c* smears from pons after preservation in 50 per cent glycerol Giemsa × 1 000 *d* and *e* areas adjacent to perivascular infiltration in the pons, Gram Weigert × 1 000

remained well, and sections of the brain and cord eighteen and twenty-one days after injection, respectively, revealed no changes One rabbit died the eleventh day No gross lesions were found in the brain or the cord The peritoneal cavity contained a fine fibrinous film and a moderate quantity of clear fluid Cultures from the blood and the brain, and from the filtrate of the brain in glucose-brain broth and in ascites

tissue fluid remained negative The emulsion of the brain of this rabbit was injected intracerebrally into one rabbit and the filtrate of the brain emulsion into two rabbits All remained well for eleven days They were chloroformed Sections of the brain and the cord were normal The emulsion of the brain of the rabbit injected with the brain emulsion was injected into two rabbits, and the filtrate into one Again all three rabbits remained well

A pure culture of the green-producing streptococcus was isolated from the emulsion of the brownish lesion at the base of the brain of the patient This culture was rapidly transferred in warm glucose-brain broth, from three to six subcultures being made every twenty-four hours for forty-six culture generations When in the tenth subculture, 0 1 c c was injected intravenously into one rabbit (R 2524) and 0 1 c c of a 1 100 dilution intracerebrally into another rabbit (R 2526), and the nose of one (R 2521) was packed with gauze soaked in the fresh undiluted culture The rabbit injected intravenously did not develop symptoms, and was chloroformed eleven days after inoculation The cultures from the brain and the blood were negative Sections revealed moderate round-cell infiltration immediately surrounding the left lateral ventricle (Fig 7) The rabbit injected intracerebrally with the diluted culture acted peculiarly at 7 o'clock the morning after the day of injection It stretched its head far forward slowly, and when forced to hop it often bumped its nose into the side of the cage At 12 m, its condition was about the same, at intervals it still acted peculiarly as if mentally deranged The respirations were increased, and tremor of the anterior part of the body had developed At 4 p m it continued to act in a singular manner, pushed its nose into the side of the cage and under its mates, and at intervals turned its head sharply to the right It had developed twitchings of the right eyelids In the morning of the second day after injection it was found dead The vessels of the meninges were markedly congested Cultures from the brain yielded a pure growth of the green-producing streptococcus, those from the blood remained sterile

Rabbit 2521, weighing 2000 gm, whose nose was packed, April 13, had developed purulent discharge from the right nostril the following day, but otherwise it appeared well when the pack was removed April 15, at 7 a m, the animal was tremulous and hyperesthetic, and the hind extremities

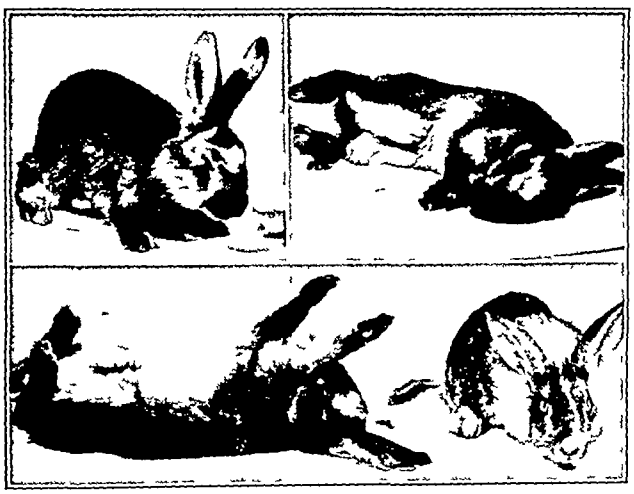

Fig 5—Rabbit 2523 showing marked lethargy with normal control

were definitely weak At 3 p m, the respirations were increased, and horizontal nystagmus with twitchings of the eyelids was noted There were peculiar tic-like movements of the head, with a tendency to retraction, but no spasms At 3 30 p m, the animal lay quietly, with almost complete paralysis of the hind extremities, and chorea-like movements of the head, which was tilted somewhat to the left The horizontal nystagmus continued and was synchronous with respirations At 6 p m, the animal was restless It made repeated violent efforts to get on its feet and to hop, but was unable to do so on account of weakness in the extremities It threw its head from side to side, and nystagmus was more marked At 7 p m, the condition was unchanged The following day its respirations were slow, it was extremely weak, and the fore and hind extremities were completely paralyzed At 10 30 a m, it was found dead

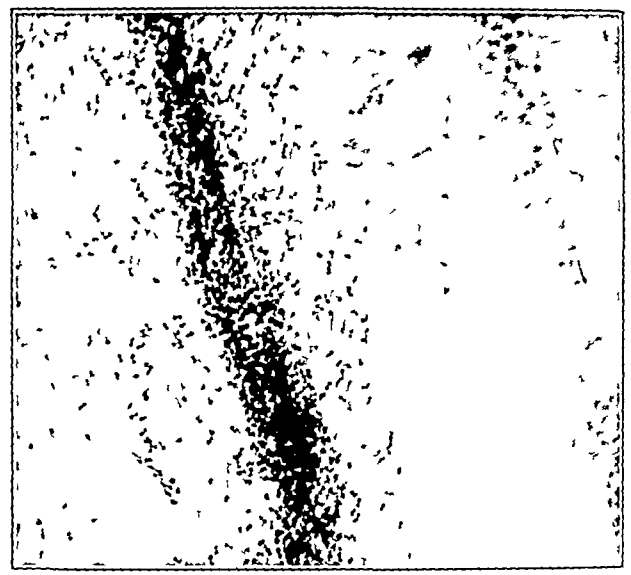

Fig 6—Section of cerebrum of rabbit shown in Figure 5 area of round cell infiltration along a blood vessel in the corpus striatum hematoxylin and eosin × 100

At necropsy, numerous hemorrhages were found in the medulla and throughout the length of the cord, which were most marked in the lumbar enlargement The cerebrospinal fluid was somewhat turbid The pia covering the pons, cerebellum and medulla was edematous Smears revealed leukocytes mononuclear cells and streptococci Cultures from the brain yielded large numbers of green-producing streptococci, those from the blood yielded a few colonies of the same organism in pure culture Sections of the brain showed marked perivascular and moderate diffuse leukocytic infiltration in the meninges, and perivascular infiltration in the cerebrum, especially marked at the base

The fresh five-hour culture from the base of the brain in the forty-sixth culture generation was injected intracerebrally into two rabbits, one receiving 0 1 c c, the other 0 1 c c of a 1 100 dilution Both died within forty-eight hours of meningitis, and cultures from the brain yielded countless numbers of the organism injected in pure form

One other rabbit was injected intracerebrally with 0 1 c c of a 1 100 dilution of the same culture after it was incubated at room temperature for forty-eight hours and exposed to direct sunlight for one hour The plating of this culture at the time of injection still showed countless numbers of the green-producing streptococcus, but the animal remained well

Besides the foregoing experiments protection experiments with the monovalent antiencephalitis serum (H 18) were undertaken in rabbits and mice Assuming that the spinal fluid and filtrate of brain emulsion would prove infectious, two sets of rabbits (six each) were injected intracerebrally with 1 5 c c each of the spinal fluid and the filtrate of the brain emulsion treated as follows

Two rabbits were injected with the spinal fluid incubated for two hours with equal parts of salt solution, two with the spinal fluid treated with equal parts of normal horse serum, and two with the spinal fluid treated with equal parts of immune horse serum In the second set, six rabbits were injected with the filtrate of the brain emulsion treated in the

same way with salt solution, normal horse serum, and immune horse serum, respectively Of the twelve rabbits injected, all remained well except one, which died of intercurrent infection (snuffles) four days after inoculation Cultures from the brain and blood yielded gram negative bacilli, sections of the brain were negative

The protection experiments in mice were undertaken with the strain isolated from the apex of the infected incisor after one animal passage, and with the culture from the base of the brain of the patient, both being in the tenth culture generation Five hour cultures of these strains in glucose-brain broth were injected intraperitoneally in doses from 1 5 to 0.25 cc, as indicated in Table 1 In each series, one set

TABLE 1—SUMMARY OF PROTECTION EXPERIMENTS IN MICE

	Strain Isolated from the Infected Tooth			Strain Isolated from the Brain		
Dose in Cc	Series Untreated	Series Treated with Normal Horse Serum	Series Treated with Antiencephalitis Serum	Series Untreated	Series Treated with Normal Horse Serum	Series Treated with Antiencephalitis Serum
1 5	Death	Death	Death	Death	Death	Death
1 0	Death	Death	Survived	Death	Death	Survived
0 5	Survived	Survived	Survived	Death	Survived	Survived
0 25	Death	Survived	Survived	Death	Survived	Survived

of mice was used as controls One set was given subcutaneously 0 2 cc of normal horse serum at the time of the intraperitoneal injection, and one set 0 2 cc of antiencephalitis serum (H 18) All but one of the untreated mice in the two series died The normal horse serum appeared to have slight protective effect The four animals injected with the two smaller doses survived The antiencephalitis serum had more marked protective power Only two of the eight mice, those receiving the largest dose, succumbed Of the thirteen mice that died, death occurred within forty-eight hours in nine, three died on the third day, and one on the fifth

The strains from the tooth and the brain produced small, sometimes umbilicated, nonadherent, greenish colonies on

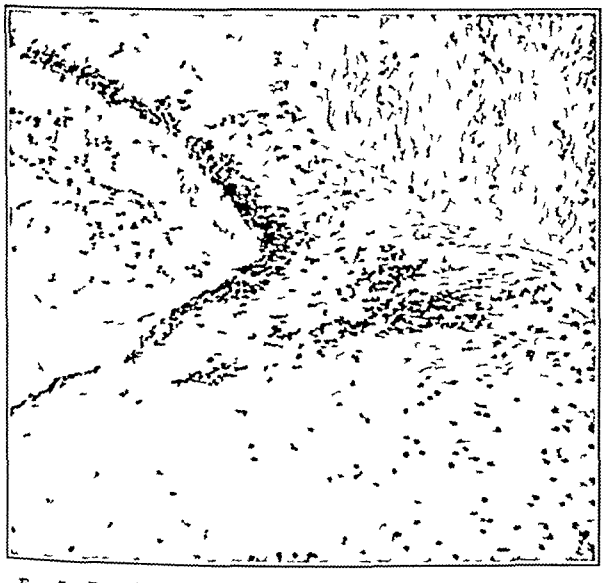

Fig 7—Round cell infiltration adjacent to lateral ventricle in rabbit (R 2524) injected intravenously with the culture from the brain after ten subcultures hematoxylin and eosin × 100

blood agar plates, and a diffuse growth in glucose-brain broth The organisms varied greatly in size, depending on the age of the culture and on the medium (Fig 8) Large, swollen, elongated cocci and diplococci often appeared to be dividing longitudinally and transversely The organisms grown in ascites tissue fluid were smaller and more regular in size than those in glucose-brain broth The fermentation powers of the two strains were identical Glucose, lactose, maltose and saccharose were fermented, inulin, mannite and salicin were not Both strains were insoluble in bile

AGGLUTINATION EXPERIMENTS

The agglutination experiments are summarized in Table 2 The antigens used were fresh cultures in

antigen, and the agglutination recorded within ten minutes The poliomyelitis, encephalitis, and influenza immune serums were prepared in horses by repeated injections of green-producing streptococci isolated in these respective diseases Partial agglutination of the primary culture from three possible infection atriums, gum abscess, pyorrhea pockets and nasopharynx, occurred in the antiencephalitis serum in the first two (Experiments 1 and 2), but not in the last (Experiment 3) The primary culture and the third culture

generation of the filtrate of the nasopharyngeal washings were agglutinated by the antipoliomyelitis and the antiencephalitis serums, and slightly by the antiinfluenza serum (Experiments 4 and 5). Similar results were obtained with the strain isolated from the blood during life (Experiments 6 and 7). Experiments 8 to 12 indicate the results obtained with the streptococcus isolated from the brain under different conditions. It was agglutinated specifically by the antipoliomyelitis and the antiencephalitis serums as isolated (Experiment 8), and after forty-eight rapidly made subcultures (Experiments 9 and 10). After sixty-five rapidly made subcultures there was a shifting of agglutination to Type II antipneumococcus serum (Experiment 11), and after many subcultures nearly a year later (Experiment 12) it was agglutinated by all the serums. Experiments 13 to 20 indicate similar results obtained with the strain isolated from the infected tooth. Specific agglutination occurred in either or both the antipoliomyelitis and antiencephalitis serums as isolated, and after many rapid transfers (Experiments 13 to 19), but not after prolonged cultivation (Experiment 20). Both strains appear to have become saprophytized after long residence on artificial mediums, as they were agglutinated by all the serums.

SUMMARY

The etiologic relationship of the foci of infection and of the green-producing streptococcus to the encephalitis in this patient seems to be established. The organism was isolated from the infected teeth, from the filtrate of the nasal washings, from the blood during life, from an emulsion of the base of the brain after death, and from the filtrate of the brain emulsion. It was demonstrated in the lesions after prolonged search (Fig. 4), and proved to be absent elsewhere. The microscopic changes in the brain were typical of this disease (Figs. 1 and 2). The streptococcus from the infected teeth, from the blood, and from the base of the brain was identical in morphology, cultural characteristics, and in immunologic properties (Table 2). The strains, isolated from one infected tooth and from the brain, possessed well marked neurotropic properties. The chief symptoms of the patient, such as lethargy, weakness of the extremities, oculomotor disturbances, spasms and tremors of muscles, and apparent mental derangement, were produced by intravenous and intracerebral inoculation of small doses, and by packing the nose with gauze soaked in the culture, even after many subcultures. The lesions of the brain and the cord of the animals were also characteristic. The organism was isolated from the brain and the spinal fluid, and demonstrated in the lesions in the animals showing symptoms and those examined relatively soon after inoculation. In those that recovered and were chloroformed long after injection, the demonstration of the organism was often impossible.

In a series of similar experiments with material from normal throats, the streptococcus having these peculiar properties was not found. Of the fourteen rabbits injected intracerebrally with salt solution suspensions of nasopharyngeal swabs from fourteen normal persons, five died of meningitis within forty-eight hours. In four green-producing streptococci, and staphylococci, and in one hemolytic streptococci were isolated. The green-producing streptococci were not agglutinated by the antiencephalitis serum, and sections of brain and cord showed only leukocytic infiltration of the meninges. Nine remained well and were chloroformed for examination in from ten to nineteen days after injection. Cultures of the brain, the spinal fluid, and the blood were negative, and sections of the brain and the cord revealed no changes.

The hemolytic streptococcus isolated from the blood of the patient after death produced suppurative meningitis when injected intracerebrally. The negative results following intracerebral injections in twenty-six rabbits and one monkey, of brain emulsions, filtrates of brain emulsions, filtrates of nasal washings, sediments of the dehemoglobinated blood, from which the characteristic streptococcus was isolated, of spinal fluid, and brain emulsions and filtrates of animals which were injected with these and did not develop symptoms, may be interpreted as proving that a filtrable virus, as usually understood, was absent in this case, and that the infecting power of the relatively few streptococci in these materials was insufficient to overcome the resistance of the animals.

The agglutination and protection experiments with the monovalent antiencephalitis serum prove the close relationship of the streptococcus from this case to the one isolated from the case of typical epidemic (lethargic) encephalitis with which this serum was prepared.

The similarity in cultural characteristics and immunologic properties of most of the strains isolated from the different cases studied has been demonstrated. Mice and rabbits have been protected with this serum against the heterologous strains. Moreover, encouraging results have been obtained in a number of patients to whom it was possible to administer the serum soon after the onset of symptoms of encephalitis. These and other findings will be reported in detail elsewhere.

ABSTRACT OF DISCUSSION

DR. LEWIS J. POLLOCK, Chicago: I should like to ask Dr. Rosenow, first, as to whether the perivascular infiltrations noted in the brain were present to any marked degree in other organs of the body, and, second, whether any particular part of the brain showed a specific vulnerability to the pathology produced by this diplococcus.

DR. E. C. ROSENOW, Rochester, Minn.: There was marked evidence of the tendency of this organism to localize in the basal ganglions of the brain. This occurred not only on intracerebral inoculation, but also following intravenous inoculation and following the packing of the nose with gauze soaked in the culture. The sections of other organs showed no perivascular infiltrations and no other noteworthy lesions, aside from moderate cloudy swelling.

The Swedish Race Institute.—During the first year of the working of this state supported institution at Upsala, Sweden, the research was restricted to a single province, but it is proposed to extend the work throughout the whole country, compiling data on heredity from the standpoints of physiology and pathology. A museum is planned, as well as experimental research. The commission in charge has seven members, including Dr. Lundborg, the director. The staff consists of the archives custodian, a medical assistant, a genealogist, an anthropologist and a photographer. The settled character of most of the population in Sweden and the way in which the generations succeed each other in the same rural district renders Sweden peculiarly favorable for research on heredity. Lundborg has published in the *Svenska Lakaresallskapets Handlingar* a number of studies on racial and culture problems in the light of medical biology.

CARE OF THE BLADDER IN PREGNANCY, LABOR AND THE PUERPERIUM *

H. W. SHUTTER, M.D.
MILWAUKEE

The intimate relationship both anatomically and functionally between the bladder and the female generative organs is largely overlooked in our management of the parturient woman. When we remember that, for the most part, the female bladder has its blood, lymphatic and nerve supplies in common with the generative organs, we are in a position to realize that the changes of pregnancy in the uterus and vagina must largely be duplicated in the bladder. Congestion, edema, increased vessel caliber, hypertrophy of the mucosa and muscle coats, increased capacity and altered form are all changes which the bladder shares with the pregnant uterus.

THE BLADDER IN PREGNANCY

Pelvic congestion and the direct pressure of the enlarged uterus, as yet a pelvic organ, account for most of the bladder symptoms of the first trimester. Increased vascularity of the bladder wall can be noted with the cystoscope as early as the sixth week. The trigon is naturally the first area to show this change. Radeaux[1] showed that sixty-three out of a series of 124 pregnant women had bladder symptoms at some time during the nine months. Twenty-six of the sixty-three had symptoms in the first trimester. Frequency, dysuria, bladder pain and hemorrhage are the complaints in the order of frequency.

As the uterus increases its anteroposterior diameter the space available for bladder expansion in that direction is diminished. The result is a pocketing of the bladder at the sides. With the woman on her feet and the uterus in anteversion, the fundus presses the bladder walls downward and forward against the symphysis. Dysuria is often the result, especially in a woman forced to be continually on her feet. Rest in bed will relieve these patients.

Urinary frequency, when not associated with infection, usually disappears when the bladder rises out of the pelvis. Bladder hemorrhage occurring at or after the end of the first trimester can usually be demonstrated as coming from varices in the wall. There are a few cases of retention reported developing in early pregnancy in women neurologically and serologically negative with uteri apparently in normal position. One such case which I saw cleared up when the woman aborted spontaneously.

Malpositions of the pregnant uterus, particularly prolapse and retroversion, produce the most serious complications of the first trimester. retention, overdistention, cystitis and possibly slough of the bladder mucosa. The degree of retroversion regulates usually the type and time of onset of bladder symptoms. If the cervix is thrown against the symphysis or into the region of the trigon, symptoms develop early. Dysuria, inability to urinate, the incontinence of retention and the discomfort and pain of distention are the early symptoms. If reposition of the uterus is accomplished at this time, bladder infection may not develop. Occasionally it is necessary to open the abdomen in order to replace the uterus. High fever, rapid pulse, malaise, abdominal and kidney tenderness, vomiting, delirium and shock are reported in the graver cases. Sudden withdrawal of the entire bladder content has been followed by hemorrhage and shock. The use of a trocar is occasionally necessary to empty the bladder. As the condition in the advanced cases is a gangrenous cystitis, the production of a vesicovaginal fistula admits the passage of the slough, resulting frequently in recovery. Deaths have been reported from hemorrhage, shock, bladder rupture, peritonitis and resulting kidney involvement.

Pelvic congestion and edema associated with mild retention and moderate malposition of the pregnant uterus predispose to bladder infections which appear in the latter part of the first trimester and later throughout pregnancy. We now know, however, that there is no justification for the diagnosis of cystitis in pregnancy unless the kidney pelves have been excluded. Torsion of the ureter due to uterine dextroversion and urinary retention are now believed to be the chief factors in the production of pyelitis in pregnancy. Weibel[2] had difficulty in catheterizing the ureters of forty-six out of 100 pregnant women. The same author believes that the staphylococcus and streptococcus infections of the renal pelvis are of the ascending type and that infection with *B. coli* occurs only in the presence of urinary and intestinal stasis. Research has shown that infection of the kidney may enter through several paths. Embarrassment of bladder function, due to the increased size of the uterus, predisposes to urinary infection in the latter two thirds of pregnancy. Frequency and burning urination should always direct one's attention to the urinary system when unilateral pain, either abdominal or dorsal, is a complication of pregnancy. One is never justified in operating for acute abdominal conditions until the kidney pelves and the bladder are proved negative. Tenderness in the costovertebral angle is not constant in pyelitis. It is surprising how quickly pain is relieved in the ordinary case, once the patient is off her feet. Milk diet, free catharsis, posture, acid sodium phosphate and hexamethylenamin bring relief in most cases. Catheter drainage, while necessary in the graver cases, is advocated largely by the urologic surgeons. If the condition is so serious as to make the induction of premature labor necessary, one can be sure that the termination of labor alone will not cure the condition. Every case of pyelitis must be carefully followed after labor.

In the last months of pregnancy, owing to the pressure of the presenting part against the bladder and urethra, one meets patients complaining of frequency, incontinence and occasional ischuria. These symptoms naturally appear earlier in primiparas. Occasionally, pyelitis develops or reappears at this time. The actual bladder space has been largely obliterated, and the organ sacculates at the sides, the so-called saddle bag bladder. Residual urine is present in many of these patients. One frequently notes, while performing a cesarean section, that, owing to the altered contour of the bladder, the preliminary catheterization has been incomplete.

THE BLADDER DURING LABOR

The onset of labor finds only the upper portion of the bladder in the abdomen. As the cervix dilates and

2. Weibel: Arch. f. Gynak. **99, 100**, 1913.

the lower segment retracts, the vesical walls are carried upward Late in labor the urethra has been shown to be definitely elongated The bladder base is lower in the female than in the male, and its tense, ligamentous attachments predispose it to traumas in the expulsive stage The woman with a contracted pelvic outlet in the anteroposterior diameter, or a generally contracted pelvis, is predisposed likewise to injury of the supporting structures of the bladder and urethra

Reflexly, as well as by actual obstruction, the full bladder delays dilatation of the cervix and expulsion of both fetus and placenta The tendency to allow women to labor with considerable quantities of urine in the vesical cavity predisposes to separation of the pubovesical ligaments and subsequent relaxation of the vaginal wall, cystocele and urethrocele Owing to the stretching of the interureteral ligament at the end of pregnancy, the ureter orifices tend to remain open, and the stress and strain of labor, with the increased bladder pressure during the expulsive efforts, may light up old infections of the kidney pelvis and bladder

Skene [3] and Emmett,[4] who in their day saw large numbers of bladder injuries, have left us many vivid descriptions Emmett said that injuries to the urethra were far more common than third degree tears Both authors showed that the majority of injuries in the first stage occurred above the trigon, those of the expulsive stage were located at or below that structure Winckel, from necropsy material, and Ruge [5] and Stoeckel,[6] with the cystoscope, showed that the bladder and urethra receive injury in practically every labor Laceration, edema, contusion and hemorrhage were most common and pronounced in the bladder of the primiparous woman Long labor, instrumentation, contracted pelvis and dry labor predispose to trauma Ruge showed that the postpartum difficulties with the bladder occurred in direct proportion to the amount and severity of the injury to the bladder wall All cases in which hemorrhage in the wall of the bladder was demonstrable with the cystoscope required catheterization Injuries to the ligamentous bladder attachments are probably more common than those demonstrable in the wall "The crying need of obstetrics," says one authority, "is a method of detecting these injuries before fascial retraction and atrophy set in"

Formerly, vesicovaginal fistulas were not uncommon as a complication of labor Skene and Emmett both showed that necrosis through the prolonged pressure of labor was the most common cause of this complication With more modern methods at our disposal, this is probably not true Whenever possible, rents in the bladder wall are repaired at once If the lesion is due to devitalization and necrosis, it will not appear for a number of days and its repair is attempted some time later

Peterson and Williams have shown that fistula is not an uncommon sequel of vaginal cesarean section and pubiotomy Vaginal cesarean section in the last few weeks of pregnancy is particularly liable to result in injury to the bladder As the bladder rests more to the right than to the left, pubiotomy is preferably done on the left side Cases have been reported in which the bladder has been caught between the separated ends of the pubic bone, following pubiotomy Constant pressure against the hips usually prevents this Separation of the bladder attachments by the rotation of forceps or craniotomy is often accompanied by infection in and about the bladder Bladder stones are occasionally reported as having obstructed labor The larger stones were formerly treated by the production of a vesicovaginal fistula With hospital facilities available, abdominal cesarean section would seem a better method of treatment

The most common measures for the protection of the bladder in labor are, briefly, as follows

1 Careful prenatal observation and diagnosis will give us an idea of the presence of old bladder lesions and infection, the presence of probable disproportion, and the possibility of interference being necessary at delivery

2 Preservation of the membranes is conducive to shorter labors, better cervical dilatation and more complete retraction and bladder elevation

3 Nurses and interns must be taught to keep the bladder and rectum of the parturient woman empty Every operative delivery is preceded by careful catheterization

4 Episiotomy releases the head posteriorly, takes off the pressure under the symphysis, and frequently spares the forceps

5 Interference, whether it be forceps, extraction or craniotomy, should not be carried out in the presence of an undilated cervix

6 The use of a flat retractor between the head and the bladder, advocated by Pomeroy, is of value when traction is necessary

7 In dealing with posterior positions of the occiput, rotation with the forceps is dangerous One cannot injure the bladder by manual methods of rotation

THE BLADDER AFTER LABOR

The most common bladder complication of the puerperium is overdistention and ischuria Holste [7] catheterized thirty puerperal women daily for a week after labor Catheterization was performed immediately after voiding, and the urine obtained was measured Twenty-four hours after delivery he found a residual urine averaging 107 c c in the primiparas and 58 c c in the multiparas This gradually diminished At the end of a week it averaged only 14 c c in the primiparas and 7 5 c c in the multiparas He concluded that usually puerperal women do not empty the bladder completely In 1912, Steuernagel [8] measured the capacity of the female bladder at the various periods of pregnancy, labor and the puerperium He showed that there is a steady increase in capacity after the fifth month In the nonpregnant the bladder usually, as the patient says, "feels full" when 200 or 250 c c of sterile boric acid solution is introduced The woman at term, Steuernagel found, did not develop this desire to urinate until 350 c c of the solution had been introduced Under slight pressure she could tolerate 800 c c of solution in the bladder, as against 500 c c in the nonpregnant The striking thing about these researches was that the patients from twenty-four to forty-eight hours postpartum did not develop desire until about 1,000 c c was in the bladder Under pressure they tolerated 2,000 c c , in other

words, the capacity of the puerperal bladder was four times that of the nonpregnant

In 1921, Walker[9] of Baltimore published an article giving the bladder pressure in millimeters of mercury in healthy males, at rest This he did by attaching a blood pressure machine indirectly to a catheter He found that when no expulsive efforts were made the manometer rose to 12 or 16 mm of mercury, according to the amount of urine or sterile solution in the bladder If more than 400 c c was introduced, the pressure fell slightly Following this idea, we found that the pressure in healthy females was slightly less than in males With this in mind, several puerperal women, unable to void, were catheterized and the bladder pressure measured On the whole, they showed pressures averaging from 2 to 6 mm , or from one-fourth to one-third below that of the nonpregnant woman with a corresponding amount in the bladder This work is still fragmentary, and will be reported in detail later It is mentioned only as a phase in the subject of residual urine and retention

All of us have noticed, I think, that the more extensive the repair work done after labor, the more likely the patient is to require catheterization This is not surprising when one remembers that the pudic nerve supplying the perineum and vulva leaves the cord at about the same level as the nerves supplying the hypogastric plexus The presence of large vaginal clots, a poorly contracted uterus, or an overfilled rectum favors retention and ischuria Olshausen believed that catheterization after labor is necessary largely because of the elongated kinked urethra Scanzoni and Winckel believed retention due to the inability of the bladder muscle to act Schroeder says that the sensation of distention is less effective in the puerperal woman Contracture or edema of the bladder neck, often considered a factor in these cases, is certainly seldom noted on passing the catheter Reflexes set up by the pain experienced when urine comes in contact with injuries of the urethra or vulva have been cited as a cause of retention Hysteria, posture, primiparity and decreased abdominal pressure are all factors in this condition Postpartum sepsis produces retention appearing several days after labor from causes similar to those producing intestinal paresis in these cases As a poorly contracted uterus predisposes to retention, so does retention tend to prevent firm contraction of the uterus Careful consideration of retention convinces one that there is no single etiologic factor in any given case

Pathogenic bacteria deliberately injected into healthy bladders have failed to produce infection in the absence of injury or residual urine "When catheterization," says Curtis,[10] "is performed for indications other than the relief from retained urine, subsequent infection is a rarity On the other hand, catheterization to relieve a distended bladder is followed by infection in spite of the greatest care" Postpartum accumulations of urine invite cystitis Authors disagree on the prevalence of pathogenic bacteria in the bladder of the female Unpublished work now being done in one of the larger clinics will probably show that pathogenic bacteria are present in the bladders of a considerable percentage of women in labor The normal changes of pregnancy in the bladder therefore, plus the injuries of labor, provide all the factors necessary for the production of infection What, then, is to be our course in preventing and combating puerperal overdistention, ischuria and cystitis?

The bladder should be emptied before the woman leaves the delivery table

As soon after labor as is reasonable, she should be urged to void If necessary, she may be propped up in bed to accomplish this

Overdistention should not be allowed to develop If the woman cannot be made to void, and in one's opinion the bladder is full, she should be catheterized

The care of the bladder should not be left to an inexperienced attendant

Strychnin, ergot and pituitary extract are sometimes of value in stimulating the bladder muscle, especially when augmented by the increased intra-abdominal pressure of the erect posture

A hot enema, the electric current and suggestion are often effective

Hexamethylenamin, in combination with acid sodium phosphate, should be given by mouth in most cases in which catheterization has been necessary

After each catheterization, a dram of 20 per cent argyrol should be left in the bladder

If pus appears in a urine previously clean, daily irrigations of warm sterile boric acid solution usually clear the condition rapidly

Barnes,[11] Skene and Chamberlain[12] all showed many years ago that once a patient is catheterized, even though she later voids spontaneously, the procedure should be repeated at least once daily until bladder tone has returned and residual urine has disappeared That failure to do this is the most common cause of our so-called catheter cystitis has been shown by Taussig, Dudley,[13] Curtis and Sampson[14] Once catheterization is necessary, its repetition for the prevention of a large alkaline accumulation is a conservative procedure

Urinary incontinence following labor has no single cause Usually one suspects the incontinence of retention Skene described overstretching of the bladder neck due to pressure of the presenting part as a cause of puerperal incontinence Temporary paralysis and lacerations of the urethra, sphincter and bladder wall must be considered in each case If incontinence occurs soon after labor, one may suspect traumatic fistula or sphincter relaxation The incontinence associated with sepsis, and the incontinence of fistula from pressure necrosis, are delayed in appearance The treatment of each case varies with the origin Strychnin and electrotherapy may be of value in paralysis and overstretching of the sphincter Lesions of the bladder wall are repaired at once, if found at or soon after labor

Injuries to the pelvic portion of the ureters are not infrequent Long, dry, tedious labors, the presence of disproportion, poor retraction and operative interference predispose to these injuries Involvement of the ureter in inflammatory exudates is sometimes seen The older gynecologists described the pathology and symptomatology of this condition in detail Tenderness over the ureter, and temperature falling with the appearance of pus and blood in the urine, are the common findings of importance Catharsis, bladder

irrigations and forced fluids are indicated in the medical treatment If drainage of the kidney pelvis by catheterization seems advisable, it should be done by an expert, bearing in mind the possibility of perforation

Pyelitis or pyelonephritis as a complication of the puerperium is closely associated with the presence of a residual urine and the possibilities of poor kidney drainage The infection at this time is frequently more active and persistent than when occurring in midpregnancy Patients suffering from pyelitis at some time previous to labor may light up the infection in the puerperium [15] Wallich [15] advises frequent catheterization for the woman who is delivered during an acute attack of pyelitis, the idea being to keep the infected urine off the vulva Smith [16] found the colon bacillus in twenty-two out of twenty-three postpartum urinary infections Forced fluids, milk diet, free catharsis, the bland oils and alkalization or acidification of the urine, according to the type of infecting organism, are indicated Drainage of the kidney pelvis may be necessary

One should be on guard against urethrocele, cystocele, rectocele and prolapse after labors when there is any possibility that the bladder attachments or the tissues of the musculomembranous diaphragm about the cervix have been injured Immediate repair of the perineal and other ascertainable injuries should be done after labor These patients should not be allowed to return to active life as soon as the normal parturient They must be taught to keep the bladder and rectum empty, thus preventing overstretching of the weakened tissues Detailed instructions are given as to the daily use of long, hot vaginal douches, which aid in restoring tissue tone Frequently a pessary, worn for a short time, will prevent permanent trouble When successful repair of the bladder supports or fistula has been performed with difficulty, cesarean section is without doubt justified in subsequent pregnancy We believe that recent years have shown a diminution in the amount of damage done to the bladder and pelvic tissues during labor When forceps and extraction have not been employed without regard to the condition of the cervix and the soft parts, follow-up work reveals very little serious damage to the bladder and its supports In no part of our obstetric practice will a little care, patience and personal attention be more richly rewarded than in the consideration of the bladder complications

ABSTRACT OF DISCUSSION

DR. ARTHUR H CURTIS Chicago The cardinal principle which underlies the care of the healthy bladder should be the avoidance of residual stagnant urine This is not only true of the bladder during labor and the puerperium, but is doubly more important after operation on the pelvic organs In my experience, one of the most important causes of the pyelitis of pregnancy is ascending infection from stagnant bladder urine I am convinced also that passage of the catheter has been unjustly blamed as the cause of so-called postoperative catheter cystitis, whereas the condition is really due to ascending infection from stagnant bladder urine We have established this rule If it is necessary to catheterize a patient several times, because of inability to empty the bladder, a catheter is passed once each day to relieve the bladder of the residual urine Ordinarily, before the catheter is withdrawn, we instil a small amount of weak silver nitrate solution, we also give a urinary antiseptic by mouth The point I wish to emphasize particularly is that it is the stagnant residual urine that causes the trouble Formerly we used the procedure in common practice—that of passing the catheter when the patient had distress, and as soon as she developed the power of spontaneous micturition, we discontinued the use of the catheter Here is the great mistake It is not the passage of the catheter but it is discontinuing the use of the catheter before the patient can learn completely to empty the bladder which causes the trouble Formerly, one out of every fifteen or twenty patients came back after operation with urinary tract infection After establishing the simple procedure of avoiding residual urine in all patients whom it has been necessary to catheterize repeatedly, we absolutely rid our service of these urinary tract infections I have recently gone over the histories, and in more than a thousand cases there has been almost complete freedom from urinary tract infection

DR JOHN GARDINER, Toledo, Ohio Yesterday Dr Neel stressed the fact that actual fascial flaps must be dissected loose and free to get the proper support for the repair of cystocele And Dr Spalding brought out, as a pertinent point, the result of excessive dilation of the fascial support of the uterus, and called attention, by way of a warning, to the injudicious use of the Voorhees bag, which, by dilating and stretching, may tear the unstretched fascia supporting the uterus And further, Dr Ward clearly pointed out the result of laceration of the posterior pelvic support which, after being torn, allows an insidious falling of the posterior culdesac and a hernia follows These are very important points in the consideration of the pelvic fascia From the obstetric standpoint, there is the fetal ovoid about 10 cm in diameter and about 30 cm long Not only is there a dilatation but also a progressive grinding downward and expulsion of the ovoid through the birth canal This muscular canal can be dilated at most about 3 cm in the nonparous woman During labor it must withstand the insult of a sphere 10 cm in diameter which is being driven down through it and at the same time being forced to accommodate itself to the irregular protuberances of the glove fitting bony birth canal Thus we have the mechanics of labor The bladder is bound to suffer more or less I have been greatly interested in the condition of the bladder, and some years ago worked out to my own satisfaction the point that the bladder and its supports were prone to be injured I used a rubber bag as a bladder, oiled it and oiled a fetus and arranged the parts as in labor As pressure was exerted on the bag, partially distended, it would rise up and as the pressure increased the lower part of the bag was pulled up When the bag was empty, it was pushed down as the fetus descended I found, clinically that there is another factor involved in the safety of the bladder A great deal depends on the formation of the symphysis pubis If the symphysis is an acute angle, the bladder usually ascends easily and is unharmed, if the symphysis is flat, it is very ominous for the bladder, if it is even convex, the bladder and urethra seemed at times to slip aside and be more or less protected I concluded from these facts that the analogy is the same during labor if the bladder is partly distended We are immediately befuddled when we are trying to bring the surgical technic in its entirety over into the obstetric technic The advice in abdominal work that patients must be catheterized is absolutely good In labor however, a different condition is being dealt with I am not making a plea that there be a distended bladder during delivery, but I would prefer that there be a full bladder rather than an entirely empty one during labor Many women are delivered, and no one has any idea as to the condition of the bladder, and no bad results have occurred If there is a distention that interferes with labor, some of the urine must be withdrawn, but by leaving some urine in the bladder, I feel that there will be less injury to the bladder and its supports However, I believe that the flat, smooth symphysis is a malformation, and the bladder and its supports during labor are in a very disadvantageous position

DR H W SHUTTER, Milwaukee I cannot agree with Dr Gardiner in leaving a small amount of urine in the bladder

15 Wallich V Pyelonephritis en suites de couches thesis Paris 1904

during delivery I cannot see its advantage, and, as most of us are unable to tell within several ounces just how much urine a bladder contains, there is a distinct possibility of harm Lack of time prevented my reading that portion of the paper considering the traumatic lesions of the bladder supports There are a number of measures that can be instituted soon after labor when the bladder has been torn loose from its attachments or when we anticipate rectocele Good care in the few weeks following delivery makes these accidents to a considerable extent preventable Overstretching of the supporting structures is prevented by keeping the bladder empty and the routine use of daily enemas Long hot douches taken daily help these women restore tone to the pelvic tissues Dr Curtis told me that every case of pyelitis complicating pregnancy that has come under his observation shows a residual urine on catheterization after voiding This coincides with the finding of the colon bacillus in twenty two out of twenty three cases of urinary infection in pregnancy reported by Dr F H Smith In other words, urinary infection is a matter of stasis and residual urine in virtually all these cases

PRIMARY CLOSURE OF WOUND WITHOUT DRAINAGE IN USUAL COMPOUND FRACTURE OF LEG*

T TURNER THOMAS, M D
PHILADELPHIA

The most common site of compound fracture is the leg, because of the unusually scanty covering of the fragments The ideal treatment is that which prevents suppuration and converts the compound into a simple fracture This has been accomplished rarely in civil life under favorable circumstances and occasionally, during the recent war, under most difficult conditions These successful results were due partly to good treatment but chiefly to the particular nature of the causal accident or injury In civil life, with which alone I am concerned, there is a marked difference in the prognosis of a case in which the fracture has been made compound by the protrusion through the skin of the sharp end of a tibial fragment and one in which a heavy, contaminated object has produced the fracture and the wound over it, thus devitalizing the neighboring soft tissues and carrying into the wound dirt and other foreign bodies Therefore, the classification of the compound fractures into those due to indirect and those due to direct violence is a very important one In my opinion, the most important question connected with compound fractures is, To which of these two varieties does each case belong? There seems to be little tendency to make this distinction, probably because of the difficulty in doing so, and the reference to it is only occasional It would seem that because we cannot establish the occurrence of the more benign indirect violence with penetration of the skin by the clean fragment, we assume the opposite conditions, that is, direct violence with more or less consequent devitalization of the soft tissues and the carrying of infection into the wound As a consequence the treatment of the great majority of cases is assumed to require free drainage I have assumed the contrary cause to be operative in the usual case

The most important evidence that the skin wound is produced by the protrusion of a fragment is its small size in almost every instance Sometimes it is very small because it is made by the pointed end of a sharp fragment and very rarely is it larger than could be accounted for by the protrusion of the entire transverse surface of the shaft of the bone If the wound were usually the result of the impact of some outside object, it would vary in size much more than it does, that is, we should more frequently find larger wounds with more irregularly lacerated margins, contused skin and subcutaneous tissues and abrasions of the adjacent skin surfaces What directed my attention particularly to the size of the wounds was a previously conceived theory concerning the mechanism of most fractures and dislocations

In 1919 I[1] offered the theory that most fractures and dislocations, which occur frequently in man, a biped, and rarely in quadripeds, are due to the ordinary fall which is common in man because he is a biped and rare in the quadrupeds Reasons were also offered for assuming that the fall on the hand was responsible for nearly all fractures and dislocations of the upper extremity and for the typical deformities characteristic of them Without attempting to follow out the exact mechanisms of them, I have, for some years, been assuming that in the lower extremity most fractures and dislocations are the result of indirect violence from a fall and that consequently most compound fractures are probably made compound by the protrusion of the fragment through the skin and not by the direct impact of some outside injuring object This would account for the usual small size of the wound, the usual absence of contusion of the soft tissues about the wound and abrasions of the adjacent skin surfaces Even when the history shows clearly that the compound fracture was due to the fall of a heavy object on the leg, one cannot say that the fracture and the skin wound over it were caused by the direct impact of this object It is quite as likely that the falling object struck the leg at some point distant from the site of the resulting fracture and skin wound and that consequently these were due to an indirect application of the force with protrusion of the fragment and a clean wound

It will, of course, be apparent that if indirect violence and protrusion of the fragment produce the compound fracture the only sources of infection to be considered are those resulting from contact of the protruding fragment and the surfaces of the wound with adjacent objects, such as clothing and soil The size of the wound cavity will be dependent on the extent of the separation of the two or more fragments from the adjacent tissues by the fracturing force which not only broke the bone or bones but also separated them from one another to a greater or lesser degree, according to the amount of force applied The inference here is that while the cavity may be a large one it is clean for the most part and its walls have suffered little devitalization

TREATMENT

Two therapeutic requirements present themselves (1) restoration and maintenance of the normal relations of the fragments to one another, and (2) the combating of any infection which has gained admission to the wound and the prevention of the introduction of any more To meet the first, I have employed the operative method with direct fixation of the fragments and one nonoperative method, the extension cast To meet the second requirement, I have provided as

1 Thomas T T Ann Surg 70 359 (Sept) 1919

irrigations and forced fluids are indicated in the medical treatment If drainage of the kidney pelvis by catheterization seems advisable, it should be done by an expert, bearing in mind the possibility of perforation

Pyelitis or pyelonephritis as a complication of the puerperium is closely associated with the presence of a residual urine and the possibilities of poor kidney drainage The infection at this time is frequently more active and persistent than when occurring in midpregnancy Patients suffering from pyelitis at some time previous to labor may light up the infection in the puerperium [15] Wallich [16] advises frequent catheterization for the woman who is delivered during an acute attack of pyelitis the idea being to keep the infected urine off the vulva Smith [16] found the colon bacillus in twenty-two out of twenty-three postpartum urinary infections Forced fluids, milk diet, free catharsis, the bland oils and alkalization or acidification of the urine, according to the type of infecting organism, are indicated Drainage of the kidney pelvis may be necessary

One should be on guard against urethrocele, cystocele, rectocele and prolapse after labors when there is any possibility that the bladder attachments or the tissues of the musculomembranous diaphragm about the cervix have been injured Immediate repair of the perineal and other ascertainable injuries should be done after labor These patients should not be allowed to return to active life as soon as the normal parturient They must be taught to keep the bladder and rectum empty, thus preventing overstretching of the weakened tissues Detailed instructions are given as to the daily use of long, hot vaginal douches, which aid in restoring tissue tone Frequently a pessary, worn for a short time, will prevent permanent trouble When successful repair of the bladder supports or fistula has been performed with difficulty, cesarean section is without doubt justified in subsequent pregnancy We believe that recent years have shown a diminution in the amount of damage done to the bladder and pelvic tissues during labor When forceps and extraction have not been employed without regard to the condition of the cervix and the soft parts, follow-up work reveals very little serious damage to the bladder and its supports In no part of our obstetric practice will a little care, patience and personal attention be more richly rewarded than in the consideration of the bladder complications

ABSTRACT OF DISCUSSION

DR ARTHUR H CURTIS Chicago The cardinal principle which underlies the care of the healthy bladder should be the avoidance of residual stagnant urine This is not only true of the bladder during labor and the puerperium, but is doubly more important after operation on the pelvic organs In my experience, one of the most important causes of the pyelitis of pregnancy is ascending infection from stagnant bladder urine I am convinced also that passage of the catheter has been unjustly blamed as the cause of so-called postoperative catheter cystitis, whereas the condition is really due to ascending infection from stagnant bladder urine We have established this rule If it is necessary to catheterize a patient several times, because of inability to empty the bladder, a catheter is passed once each day to relieve the bladder of the residual urine Ordinarily, before the catheter is withdrawn, we instil a small amount of weak silver nitrate solution, we also give a urinary antiseptic by mouth The point I wish to emphasize particularly is that it is the stagnant residual urine that causes the trouble Formerly we used the procedure in common practice—that of passing the catheter when the patient had distress, and, as soon as she developed the power of spontaneous micturition, we discontinued the use of the catheter Here is the great mistake. It is not the passage of the catheter but it is discontinuing the use of the catheter before the patient can learn completely to empty the bladder which causes the trouble Formerly, one out of every fifteen or twenty patients came back after operation with urinary tract infection After establishing the simple procedure of avoiding residual urine in all patients whom it has been necessary to catheterize repeatedly, we absolutely rid our service of these urinary tract infections I have recently gone over the histories, and in more than a thousand cases there has been almost complete freedom from urinary tract infection

DR JOHN GARDINER, Toledo, Ohio Yesterday Dr Neel stressed the fact that actual fascial flaps must be dissected loose and free to get the proper support for the repair of cystocele And Dr Spalding brought out as a pertinent point, the result of excessive dilation of the fascial support of the uterus, and called attention, by way of a warning, to the injudicious use of the Voorhees bag, which, by dilating and stretching may tear the unstretched fascia supporting the uterus And further, Dr Ward clearly pointed out the result of laceration of the posterior pelvic support which, after being torn allows an insidious falling of the posterior culdesac and a hernia follows These are very important points in the consideration of the pelvic fascia From the obstetric standpoint, there is the fetal ovoid about 10 cm in diameter and about 30 cm long Not only is there a dilatation but also a progressive grinding downward and expulsion of the ovoid through the birth canal This muscular canal can be dilated at most about 3 cm in the nonparous woman During labor it must withstand the insult of a sphere 10 cm in diameter which is being driven down through it and at the same time being forced to accommodate itself to the irregular protuberances of the glove fitting bony birth canal Thus we have the mechanics of labor The bladder is bound to suffer more or less I have been greatly interested in the condition of the bladder, and some years ago worked out to my own satisfaction the point that the bladder and its supports were prone to be injured I used a rubber bag as a bladder, oiled it and oiled a fetus and arranged the parts as in labor As pressure was exerted on the bag, partially distended, it would rise up, and as the pressure increased the lower part of the bag was pulled up When the bag was empty, it was pushed down as the fetus descended I found clinically, that there is another factor involved in the safety of the bladder A great deal depends on the formation of the symphysis pubis If the symphysis is an acute angle the bladder usually ascends easily and is unharmed, if the symphysis is flat it is very ominous for the bladder, if it is even convex, the bladder and urethra seemed at times to slip aside and be more or less protected I concluded from these facts that the analogy is the same during labor if the bladder is partly distended We are immediately befuddled when we are trying to bring the surgical technic in its entirety over into the obstetric technic The advice in abdominal work that patients must be catheterized is absolutely good In labor however, a different condition is being dealt with I am not making a plea that there be a distended bladder during delivery, but I would prefer that there be a full bladder rather than an entirely empty one during labor Many women are delivered, and no one has any idea as to the condition of the bladder, and no bad results have occurred If there is a distention that interferes with labor, some of the urine must be withdrawn, but by leaving some urine in the bladder, I feel that there will be less injury to the bladder and its supports However, I believe that the flat, smooth symphysis is a malformation, and the bladder and its supports during labor are in a very disadvantageous position

PRIMARY CLOSURE OF WOUND WITHOUT DRAINAGE IN USUAL COMPOUND FRACTURE OF LEG*

T TURNER THOMAS, M D
PHILADELPHIA

The most common site of compound fracture is the leg, because of the unusually scanty covering of the fragments The ideal treatment is that which prevents suppuration and converts the compound into a simple fracture This has been accomplished rarely in civil life under favorable circumstances and occasionally, during the recent war, under most difficult conditions These successful results were due partly to good treatment but chiefly to the particular nature of the causal accident or injury In civil life, with which alone I am concerned, there is a marked difference in the prognosis of a case in which the fracture has been made compound by the protrusion through the skin of the sharp end of a tibial fragment and one in which a heavy, contaminated object has produced the fracture and the wound over it, thus devitalizing the neighboring soft tissues and carrying into the wound dirt and other foreign bodies Therefore, the classification of the compound fractures into those due to indirect and those due to direct violence is a very important one In my opinion, the most important question connected with compound fractures is, To which of these two varieties does each case belong? There seems to be little tendency to make this distinction, probably because of the difficulty in doing so, and the reference to it is only occasional It would seem that because we cannot establish the occurrence of the more benign indirect violence with penetration of the skin by the clean fragment, we assume the opposite conditions, that is, direct violence with more or less consequent devitalization of the soft tissues and the carrying of infection into the wound As a consequence the treatment of the great majority of cases is assumed to require free drainage I have assumed the contrary cause to be operative in the usual case

The most important evidence that the skin wound is produced by the protrusion of a fragment is its small size in almost every instance Sometimes it is very small because it is made by the pointed end of a sharp fragment and very rarely is it larger than could be accounted for by the protrusion of the entire transverse surface of the shaft of the bone If the wound were usually the result of the impact of some outside object, it would vary in size much more than it does, that is, we should more frequently find larger wounds with more irregularly lacerated margins, contused skin and subcutaneous tissues and abrasions of the adjacent skin surfaces What directed my attention particularly to the size of the wounds was a previously conceived theory concerning the mechanism of most fractures and dislocations

In 1919, I[1] offered the theory that most fractures and dislocations, which occur frequently in man, a biped, and rarely in quadripeds, are due to the ordinary fall which is common in man because he is a biped and rare in the quadrupeds Reasons were also offered for assuming that the fall on the hand was responsible for nearly all fractures and dislocations of the upper extremity and for the typical deformities characteristic of them Without attempting to follow out the exact mechanisms of them, I have, for some years, been assuming that in the lower extremity most fractures and dislocations are the result of indirect violence from a fall and that consequently most compound fractures are probably made compound by the protrusion of the fragment through the skin and not by the direct impact of some outside injuring object This would account for the usual small size of the wound, the usual absence of contusion of the soft tissues about the wound and abrasions of the adjacent skin surfaces Even when the history shows clearly that the compound fracture was due to the fall of a heavy object on the leg, one cannot say that the fracture and the skin wound over it were caused by the direct impact of this object It is quite as likely that the falling object struck the leg at some point distant from the site of the resulting fracture and skin wound and that consequently these were due to an indirect application of the force with protrusion of the fragment and a clean wound

It will, of course, be apparent that if indirect violence and protrusion of the fragment produce the compound fracture, the only sources of infection to be considered are those resulting from contact of the protruding fragment and the surfaces of the wound with adjacent objects, such as clothing and soil The size of the wound cavity will be dependent on the extent of the separation of the two or more fragments from the adjacent tissues by the fracturing force which not only broke the bone or bones but also separated them from one another to a greater or lesser degree, according to the amount of force applied The inference here is that while the cavity may be a large one it is clean for the most part and its walls have suffered little devitalization

TREATMENT

Two therapeutic requirements present themselves (1) restoration and maintenance of the normal relations of the fragments to one another, and (2) the combating of any infection which has gained admission to the wound and the prevention of the introduction of any more To meet the first, I have employed the operative method with direct fixation of the fragments and one nonoperative method, the extension cast To meet the second requirement, I have provided as

*Read before the Section on Surgery General and Abdominal at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Thomas T T Ann Surg 70 359 (Sept) 1919

thorough asepsis as possible to prevent the admission of new infection and direct application to the wound of tincture of iodin, with or without neutralization by alcohol and with and without the addition of the application of dichloramin-T to combat any infection introduced through the wound I have recently[2] fully described and illustrated the extension cast employed This cannot be done satisfactorily here because of lack of space The purpose now is not so much to attempt to establish exact methods of treatment as to suggest possible lines of progress toward the ideal method of treating compound fractures in general, the conversion of them into simple fractures by immediate closure of the wounds without infection

A previously entertained impression, now strengthened by experience, is that the more absolute the immediate immobilization of the fragments the better the chances of avoiding infection, indeed, too much mobility of the fragments seems capable of causing a discharge which will not behave as does ordinary pus I believe that the direct fixation of the fragments by operative means, for this reason, is better than the indirect fixation by the nonoperative methods, although this was not so definitely established as one could wish The technic of the treatment of the wound will vary with the method of fixation of the fragments For the operative method, it is essentially the same, regardless of the particular fixation apparatus used I employed plates and screws, screws alone and nails With the extension cast, the fixation is applied at one sitting and the position of the fragments does not change after the cleansing of the wound Continuous traction with gradual correction of the deformity was not employed in any of these cases

When the extension cast is to be used the wound is temporarily covered by sterile gauze and a bandage Under a general anesthetic, the extension and fixation may be applied without covering by plaster the portion of the leg containing the wound After removal of the temporary dressings the surgeon, gowned gloved and masked as for the usual aseptic operation prepares the wound area The limb, which has been previously shaved is cleansed with a sterile gauze sponge in a hemostat, while an assistant pours on ether Then the parts are draped with sterile sheets and towels, and the wound and surrounding skin are painted with tincture of iodin, which is washed off with alcohol Then with a sterile sponge in a hemostat, tincture of iodin is carried to all parts of the interior of the wound In some cases the excess of iodin was neutralized with alcohol and in some not Usually one or more sutures are employed to close a gaping wound loosely that is with spaces between the sutures wide enough to permit free escape of wound secretions into the gauze dressings After the first few cases treated in this way, the cast was then made to cover the whole limb, including the wound

When operation and direct fixation of the fragments are resorted to the patient is given a general anesthetic usually ether, and the limb is prepared carefully with ether iodin and alcohol as in the nonoperative method, the skin having been previously shaved After the draping of the field of operation with sterile sheets and towels the surgeon swabs out the entire inside of the wound with tincture of iodin It will probably prove to be best to neutralize the excess of iodin with alcohol The wound is then enlarged to permit better access to the fragments which are then approximated with as little disturbance of their attachments to the surrounding structures as possible The idea is to reach the fragments, adjust them and provide firm fixation as quickly as possible In most cases, the necessity of promptness in this treatment has prevented the taking of a preliminary roentgenogram, and this has necessitated more exposure of the fragments for the accurate placing of screws or nails across the line of fracture and through both fragments These were employed with the idea of diminishing the amount of foreign body in the wound The determination of the best mode of fixation of the fragments is a question that needs more attention By this time the iodin has largely disappeared from the wound so that I have in some cases, before closing the wound filled it with dichloramin-T In all except Case 3, drainage of the wound was avoided The tendency has been to use chromic gut No 2, interrupted sutures, and to leave free spaces between them so that wound secretions can escape easily into the dressings Sterile gauze wet with alcohol is applied to the wound and this is reinforced by a considerable thickness of dry gauze and the limb is encased in a plaster cast, extending usually to the middle of the thigh

2 Thomas J T S Clinics N America 1 207 (Feb) 1921

REPORT OF CASES

The cases reported herewith illustrate various phases of compound fractures of the leg and of the results of treatment described above In all only the tibial fracture seemed to be compound and the small size of the skin wound indicated that it was due to penetration by the tibial fragment The treatment of the wound as outlined above for the extension cast method and for the method by direct fixation with plates, screws, Parham-Martin bands, etc, will not be repeated for each case

CASE 1.—An iceman aged 43 a free user of alcohol while at work in a stable Dec 26 1918 was struck on the back of the neck by a bale of hay which fell from the floor above He sustained a fracture of both bones of the left leg a tibial fragment protruding through the skin The bleeding was not severe He exhibited a heaving impulse over the precordium and a faintly palpable thrill at the cardiac apex which was displaced downward to the sixth interspace There was moderate cardiac enlargement and pulsation of the superficial vessels of the neck He had a soft double murmur heard best over the aortic area radiating down to the sternum and not transmitted to the vessels of the neck

He was admitted to the university hospital soon after the accident The upper tibial fragment was protruding from the wound The foot and both lower fragments were displaced backward and outward The intern cleansed the wound with tincture of iodin and alcohol and applied a sterile dressing On the same day, an extension cast was applied and the wound and surrounding skin were treated by the technic outlined above The wound was then enlarged the protruding fragment released and reduced the pull of the extension cast permitting a good approximation of the fragments The wound was closed by sutures without drainage and was dressed aseptically It was not covered by the plaster cast as in later cases Healing occurred without infection The cast was removed Jan 15 1919 and an ordinary one applied The second cast became loose and a third one was applied February 8 Two days later, he was discharged In about eight weeks after the accident, the third cast was removed and the patient used crutches He returned to his work about the middle of April, but he had worked only a few weeks, when heart trouble compelled him to give up again He then remained in bed until he died in July 1918

CASE 2.—A stone mason aged 34, Dec 28 1918, sustained a compound comminuted fracture about the middle of the leg

when a large stone, weighing in his judgment about a ton, fell on his left leg His reputation for honesty and skill as a workman was such that he was probably telling the truth The upper part of the leg and the lower part of the thigh showed considerable contusion and abrasion He was brought immediately to the Northeastern Hospital, where a wound was found in the skin of the inner side of the leg, just back of the tibia, at about the junction of the lower and middle thirds, or about 4 inches (10 cm) below the site of fracture of the tibia This indicated that the upper fragment had descended that far and had produced the skin wound which was about 1½ inches (4 cm) long An extension cast was applied the same afternoon and the wound was treated by the technic described above The wound was found to be very extensive when the sterile gauze pad saturated with tincture of iodin was carried to all its parts, indicating that the tibial fragments had been extensively stripped from their attached muscles by the force producing the fracture The roentgenogram taken afterward showed excellent position of the fragments

As in the preceding case, the wound area was not covered by the cast Jan 21, 1919 a new cast was applied, the wound having healed without infection, and, February 1, the patient was discharged He was readmitted, February 25, on account of poor union of the fracture which was plated on the following day He was again discharged in a cast in two weeks with an open wound and returned, April 14, for removal of the plate and two pieces of dead bone The union was not solid and, May 22, he began to wear a walking brace He seemed to have developed solid union about July 1, but continued to wear the brace until about the middle of the following November He had begun to work as a stone mason September 1, and has continued to do so ever since, earning his full wages from the beginning He now has one half inch (1.2 cm) shortening in the affected leg, with slight external bowing but excellent function

CASE 3.—A Lithuanian laborer, aged 48, April 1, 1919, sustained a compound fracture at the junction of the lower and middle thirds when a heavy load of steel rods fell onto his right leg He lost much blood and was brought to the Northeastern Hospital immediately after the accident, where open reduction was performed within a few hours, with essentially the technic described above This was the first case of this group in which the open method was adopted and a rubber drainage tube was employed A plaster cast was applied with a hole cut in it over the wound, to enable the wound to be dressed Within a few days the edges of the wound separated slightly, exposing the plate to view Slight infection of the wound followed The tube, plate and screws were removed at the end of two weeks and a new cast was applied with an opening in it for drainage The patient was put on crutches with the idea that better drainage from the upright position would be worth while He was discharged a few days later, with the request that he return to the dispensary for further dressings The thought was entertained that because of the benign character of the wound, which discharged slightly, going about in the open air would influence favorably the healing of the wound and would bring about earlier bony union This did not meet with the patient's approval and he gained admission to another hospital, May 13

The evidence appears to show that expectant treatment was followed, that is, new and larger openings were provided and the limb was kept continuously in a cast, a new one being applied from time to time During his stay in the hospital and afterward he says that eleven pieces of bone were removed from the wounds He remained in the hospital until Nov 13, 1919 The wound has since broken open a few times, usually with the extrusion of a piece of bone, the last time in June, 1921 He returned to his usual work in May, 1920, and has been able to perform such work continuously since, except when there was no work for him He has now (April 1, 1922) three-fourths inch (2 cm) shortening, the bone is somewhat thickened about the fracture area, the bony union and motion at the ankle are excellent, and so far as he can judge the leg is as good as it ever was

CASE 4.—A boy, aged 14, was knocked down by an automobile July 4, 1919 the wheels passing over both legs and breaking both bones in each leg The fracture was compound in the left leg The patient was brought promptly to the Northeastern Hospital Dr John A Broadfield was called immediately and began to operate on the compound fracture very soon afterward There was some comminution and considerable displacement of the fragments, but by traction and manipulation, they were placed in excellent position and fixed by a plate and six screws The wound was swabbed out first with tincture of iodin and later in the operation with dichloramin-T It was closed without drainage except for free spaces between the skin sutures A plaster cast was applied The fracture of the right leg was treated in a fracture box, the deformity being slight July 8, a window was cut in the cast and the wound inspected A dark brown secretion was exuding, but evidence of infection was slight July 18, the wound was partly open and the plate was visible a creamy pus escaping The temperature rose to 100.4 F. on the day following operation, subsided to normal in about ten days and remained about normal afterward The pulse did not rise above 110 after the day of operation on which it reached 150 September 12, a new cast was applied with an opening for drainage of the wound The patient was discharged from the hospital, September 24 December 8, he was readmitted for removal of a small sequestrum and curettage of the bone in the fracture area and was discharged three days later The cast was removed March 15 1920 He began to walk first with crutches and later with a cane The wound was completely healed about the middle of June, 1920 Strong bony union developed, with slight external bowing of the leg, due to a softer union in the early weight bearing stage So far as he can judge, this limb is now (March 15 1922) as good as the other, but there is a shortening of one-half inch (1.2 cm), with perfect motion in the ankle and knee and apparently perfect strength in the leg

CASE 5.—A motor truck chauffeur aged 22, sustained a compound comminuted fracture of the tibia and a fracture of the fibula when one wheel of a motor truck passed over his left leg He was brought promptly to the university hospital where an intern found a wound in the skin about the size of a half dollar, through which the end of the tibial fragment could be seen There was free bleeding from the wound The intern cleansed the surrounding skin with tincture of green soap and alcohol, cleansed the wound and packed it with sterile gauze wet with dichloramin-T because of the hemorrhage On the same day I applied an extension cast and treated the wound with the technic described above for the extension cast cases It was observed at this time that the extension exerted on the leg by the cast rendered the skin over a considerable area of the front of the leg pale It was thought at the time that this was only a temporary disturbance of the circulation which would disappear later, especially as a similar effect had been noticed in previous cases of simple fracture of the leg with no later untoward effect December 2, the wound showed evidence of infection and on the following day a small quantity of pus was evacuated and the Carrel-Dakin technic instituted December 3 the skin over the front of the leg in the area made pale by the extension about the size of the palm of the hand, showed evidence of necrosis From this time on it was necessary to care for an increasingly suppurating wound, associated with the sloughing surface tissues Jan 10, 1920, the extension cast was removed and a fracture box was substituted the loss of the extension becoming evident in a recurrence of the deformity of the fragments January 13, under ether and with a liberal use of tincture of iodin, two Parham Martin bands were applied, which held the fragments in accurate apposition so that the fracture box could still be employed About five weeks later a posterior splint was substituted for the fracture box, which permitted better care of the discharge February 10, the Carrel tubes were dispensed with and on the following day he was put in a wheel chair March 17 since we believed that the fragments would now maintain their good position without their support, we

removed the bands from the fragments, together with a loose piece of bone However, the foot and the lower fragments from their own weight slowly turned inward, causing a slight varus deformity April 7, the patient was sent home on crutches, where the rather large granulating surface was to be treated by his family physician In September a walking brace was applied, which enabled him to walk about without the support of a cane, and about a month later he went to work in a machine shop on a drill press About Jan 1, 1921 he again gave up work and did not try again until about the middle of the following September, when he went back to his old work as a motor truck chauffeur He has been able to do this kind of work since except for the idleness enforced by the following operation March 7, 1922, in the university hospital, I performed a skin graft operation on the unhealed granulating, wound surface, which was about the size of the palm, with much success April 27, there remained three unhealed irregular spots, each approximately a half inch (1 2 cm) in diameter There was no shortening, about a half inch (1 2 cm) elevation of the heel, slight varus position of the foot and about half of the normal motion of the ankle

CASE 6—A blacksmith aged 61, slipped on the ice, Feb 8, 1920 He was brought immediately to the university hospital where he was found to have a fracture of both bones of the left leg at the junction of the lower and middle thirds that of the tibia being compound On the same day an extension cast was applied and the wound treated as outlined above A roentgenogram taken afterward showed the fragments in excellent position February 19, the leg was movable in the cast, which did not cover the wounded portion of the leg The cast was then made to cover the whole leg, a small hole being cut in it over the wound for purposes of dressing February 25 it was discharging a small quantity of pus Dichloramin-T dressings were applied April 20, the cast was removed There was union of the fracture The pus had, however, slowly increased and burrowed to the region of the ankle Under gas anesthesia better drainage was afforded at the original opening and at the ankle June 3 he was discharged to return to the surgical dispensary for dressings of the wound He reported that after two visits the wounds closed and he returned to work He gave up again in a few days on account of a perineal abscess I did not see him after he left the dispensary until March 20, 1922 In July, 1920, he was admitted to another hospital, where better drainage was provided and where he remained for four or five months He has not worked since but he intends to return to work very soon March 20, 1922 there was no sinus, he had about a half inch (1 2 cm) shortening considerable limitation of motion at the ankle and slight elevation of the heel from shortening of the Achilles tendon

CASE 7—A girl, aged 15, was admitted to the university hospital, Aug 8, 1920, with a compound fracture of the left leg With the technic described above, an open reduction was performed after the wound had been enlarged and the fragments accurately approximated and fixed by driving two long nails through both across the line of fracture which was somewhat oblique The wound was closed without drainage, a sterile dressing applied and the limb, including the wound, was completely covered by a plaster cast, extending from above the knee to, and including the foot No infection developed She was discharged, August 18, to return later for the removal of the cast

She did not return but was attended at home by her physician, Dr William B Ewing, who split and removed the cast at the end of seven weeks, reapplying it and keeping it on until three months after the fracture occurred When the cast was first removed, the gauze covering the wound was moist with a dark serum The end of one nail, which appeared at a small opening, was removed Union of the fracture was not firm until the end of three months, when the sinus was closed April 30, 1922, I found one-half inch (1 2 cm) shortening, with a very slight posterior bowing at the seat of fracture, shown by the roentgen ray The mother and the patient said that her friends could not tell from the appearance which limb had been fractured while the function of the limb was perfect

CASE 8—A boy, aged 15, Dec 7, 1920 was kicked in the right leg by a horse, a compound fracture of the tibia and a fracture of the fibula resulting He was brought at once to the university hospital and an open reduction and fixation of the tibial fragments by three nails was performed on the same day, with the technic described above The wound and dressing were enclosed completely by a plaster cast from above the knee to, and including, the foot No infection resulted He was discharged, December 21, and returned four weeks later to have the cast removed He used crutches or a cane for a month more before beginning to bear weight on the fractured leg He returned to the hospital, Aug 15 1921, with a small discharging sinus over the seat of fracture The bone was exposed and this sinus was found to come from a loose nail which was removed The other two nails were so covered by bone that they could not be found easily and were not removed The wound was swabbed with tincture of iodin and closed without drainage and it healed without infection He was seen, March 19, 1922, at which time there were perfect shape and function of the limb, with no shortening

CASE 9—A man, aged 65, spare but in good health for his age, who lived largely an outdoor life, May 5, 1921, was thrown from a railroad "work car," sustaining a compound fracture of the left leg in the lower third He was brought to the university hospital on the same day, and in the receiving ward the leg was cleansed and a sterile dressing applied by an intern The upper fragment had become engaged in the skin after penetrating it and had carried this skin back into the wound underneath On the day of admission, an extension cast was applied by the technic referred to above It was necessary to make a longitudinal incision about 2 inches (5 cm) long in order to release and reduce the engaged end of the protruding fragment Under the traction exerted by the extension cast and with a little direct pressure on them the fragments were well approximated The wound was closed by chromic gut sutures without drainage and completely enclosed in a plaster cast from above the knee to and including the foot The after-course in this case was especially interesting The temperature and pulse seemed to indicate that no infection had taken place, but soon after operation, the patient began to complain of much pain about the seat of fracture, so that it became necessary to give him morphin for relief May 20, fifteen days after the fracture and its reduction, the cast was removed in order that the cause of the pain might be discovered The removal necessitated the administration of gas-ether anesthesia The sutured wound margins had separated about three-fourths inch (2 cm) at the widest part, and the upper fragment could be seen The external margin of the wound had undergone some necrosis and the gauze covering the wound had become wet through with a discharge resembling pus The wound cavity was cleansed thoroughly with sterile gauze sponges swabbed with tincture of iodin and then alcohol, and a sterile gauze dressing, wet with dichloramin-T, was applied This was fixed by a bandage The fragments, from the loss of the special cast extension, had lost their good approximation and overlapped somewhat They were straightened as much as possible and a new cast was applied from above the knee to, and including, the foot, covering the wound and dressing completely June 7, four weeks later, it was noted that there had been no evidence of infection shown by temperature, pulse or general condition, but that for the preceding few days there had been some pain at the seat of fracture, with a slight rise in temperature which otherwise would not have been considered important On this day an opening was made in the cast and the wound exposed It was distinctly smaller and cleaner than four weeks before A new sterile gauze dressing saturated with dichloramin-T was applied and held firmly in position by adhesive plaster strips, applied over the cast opening

The patient was discharged July 15 without any inspection of the wound since the last dressing four weeks before, there having developed no signs of infection in the meantime After twenty days more, August 4, he was brought back to the hospital and the cast and dressing were removed, a very

interesting condition being disclosed When the first cast was removed and the free discharge was found in the wound, in addition to the absence of constitutional signs of infection there were no local signs, other than the discharge, that is, no redness, tenderness, edema or any appreciable thickening of the tissues Eight weeks later, without any attempt at drainage, the pushle material had entirely disappeared and the wound, so far as gross appearances were concerned, was perfectly clean The granulations, apparently from the bone, had so grown into the meshes of the gauze that the latter could be removed only by tearing away these granulations, leaving a freely bleeding surface There was good bony union This surface cicatrized without difficulty soon afterward December 28, it was noted that he was walking with a limp and was using a cane which he expected soon to dispose of He returned to office work, March 1, 1922 The roentgen ray revealed posterior angulation at the seat of fracture and he still had some elevation of the heel from contraction of the Achilles tendon With a thickening of the heel of the shoe he walks very well without support and has returned to his work in the woods as a tree inspector

CASE 10—A colored man, aged 38, Sept 14, 1921, was knocked down by an automobile, sustaining a compound fracture of the left leg in the lower third He was brought immediately to the university hospital and operated on a few hours later, the technic described above being employed The wound was about 2 inches (5 cm) long and almost transverse It was enlarged longitudinally to about 3½ inches (9 cm) in this direction after the whole wound had been swabbed out with tincture of iodin The fragments were then approximated and fixed by an ordinary wood screw passed obliquely across the line of fracture through both The wound was then closed completely, a sterile gauze dressing wet with alcohol being applied as well as a plaster cast extending from above the knee to, and including, the foot No infection followed He was discharged, September 27, walking on crutches Following a suggestion of another surgeon on this day, the cast below the ankle was removed and two "stilt" like pieces of wood splint were applied, one on each side of the cast, and made to project below the foot These were incorporated in the cast by additional rolls of plaster of-Paris bandages, the object being to furnish an ambulatory cast and allow free movement of the ankle On the following day, I permitted him to walk on this "stilt' cast November 15, about nine weeks after the operation and accident, this cast was removed and a small discharging sinus was discovered over the fracture This had been covered completely for seven weeks by the cast without giving any detectable signs of infection constitutionally or locally, the patient repeatedly having stated that he experienced neither pain nor discomfort in this region The gauze covering the wound was somewhat thicker than the hand and considerably longer and wider It was slightly moist over an area about the size of the palm, excluding the fingers, with what looked more like dark blood than pus, that had escaped from the very small sinus There were no local signs of inflammation in the surrounding skin or deeper tissues After cleansing the sinus opening and skin about it with tincture of iodin and alcohol, a sterile gauze dressing moistened with dichloramin-T, and another cast like the preceding one but including the foot and without the stilts," were applied A week later he was advised to walk on the cast, the idea being to take advantage of weight bearing for its possible influence in favoring the development of bony union Jan 3, 1922, after walking on it for fifty-one days, during which neither the wound nor the sinus was exposed, the cast was removed The sinus was still discharging and bony union had not occurred There had been no local or constitutional signs of infection at any time except the discharge January 10, the screw was removed and the bone curetted at the site of the sinus and screw The wound was then swabbed out with tincture of iodin and completely closed with catgut sutures without drainage Another cast extending from above the knee to, and including, the foot was applied Since no signs of infection developed, this cast was not removed until February 28, seven weeks after it had been applied There was now no evidence of a sinus, the wound having healed completely, but there was still motion at the seat of fracture The use of a walking brace was ordered and he began to walk on it, March 17

CASE 11—A farmer, aged 26, Oct 8, 1921, was knocked down by an automobile He was taken immediately to a neighboring private hospital where he was found to have a compound fracture of the leg with a small wound in the skin, at about the junction of the middle and lower thirds of the leg Dr Samuel Bruck was called from Philadelphia on the following day and had the patient transferred to the Northeastern Hospital of Philadelphia, about thirty six hours after the accident and I saw him soon afterward The roentgenogram taken by Dr Bruck revealed a comminuted fracture of the tibia and a fracture of the fibula, the tibial fracture being compound An extension cast was applied at once with excellent reduction of the considerable displacement, and the wound was treated by the technic described above No infection resulted The cast was removed, October 27, when the wound was healed completely A new cast was applied without including the foot and side splints were so encased in the cast that they projected below the foot like stilts, the object being to permit walking on the cast with freedom of movement at the ankle October 21, the patient was discharged to walk on crutches, but a week later he was permitted to walk on the 'stilt' cast without crutches Finding that the stilt cast in Case 10 had resulted in the formation of a sinus and delayed union, November 20, it was removed from this patient and a new cast was applied from the middle of the thigh to, and including, the foot Soon afterward he was permitted to walk on this cast without crutches Jan 10, 1922 he had been walking on this cast about six weeks when it was removed and firm bony union was found at the site of fracture January 26 he could walk very well except for an exaggeration in the foot of the fractured limb of a normal tendency to flatfoot, due to a slight abduction of the lower fragments at the seat of fracture He had normal motion in the affected ankle and a shortening of this limb of one-half inch (1 2 cm) He could then do much, but not all, of his farm work

CASE 12—A boy aged 16, Oct 29, 1921, was working as a huckster when a horse fell on him He sustained a compound fracture of the right leg, which was caught under the horse There was a wound about an inch and a half (4 cm) long on the medial side of the leg, about 6 inches (15 cm) above the ankle joint, the tibia being broken a few inches higher and the fibula at about the same level There was about an inch (2 5 cm) shortening of the limb He was brought immediately to the Northeastern Hospital, and a few hours later a longitudinal incision, about 6 inches (15 cm) long was made over the front of the tibia, not including the wound which made the fracture compound, with the technic described above The fragments were approximated and fixed by two screws, passed obliquely through both fragments across the line of fracture The wound was closed completely, and a sterile gauze dressing wet with alcohol was applied over it, the limb being completely enclosed in a cast from the toes to the middle of the thigh No infection followed He was discharged from the hospital, November 22 walking on crutches The cast was removed eight weeks after the accident and he could walk without crutches soon afterward He had not worked since the accident because he could get no work to do, but he says he was able to work a few weeks after the cast was removed April 16, 1922, he had no shortening the leg was perfectly normal in shape and length, except for slight thickening of the bone about the fracture area and he had perfectly normal function in the limb

CASE 13—A railroad brakeman, aged 39, Nov 20, 1921, while shifting cars, was sideswiped' by a passing car and thrown to the ground, his right leg especially being injured It bled profusely and he arrested the hemorrhage partially by tying a handkerchief around the leg A little later he was found by a fellow workman, who stopped the bleeding completely by tying the tourniquet tighter He was brought immediately to the university hospital where he was attended

by the chief resident physician, Dr. Cook. The upper fragment was protruding through a skin wound. The leg of the underwear had also been penetrated and had been so entangled in the fragment that it had been carried into the wound and could be withdrawn only with considerable force. The surrounding skin was cleansed with tincture of green soap and a sterile dressing was applied without reducing the fragment into the wound. A Thomas splint, with a loop of bandage around the ankle for traction, was applied. Operation was performed about five hours after admission. The skin wound was situated over the antero-internal surface of the tibia and was from 2½ to 3 inches (6.5 to 7.5 cm.) long, its edges gaping an inch (2.5 cm.) or more in its widest part. With the technic described above the wound was enlarged to about 6 inches (15 cm.), the fragments were approximated and fixed by two screws passed obliquely through both fragments, the line of fracture being only slightly oblique. The wound was closed without drainage, a sterile dressing wet with alcohol and a cast extending from the middle of the thigh to and including the foot were applied. Since no signs of infection developed, the patient was discharged, December 3, walking on crutches. The cast *was first removed and the wound exposed eight weeks later*. There was some purulent discharge and odor. A granulating surface was found along the site of the incision, about 1½ inches (4 cm.) long and about three-fourths inch (2 cm.) wide, with a small sinus extending to the seat of fracture not large enough to admit an ordinary probe. This was laid open, and the loose screws removed. The surfaces of the sinus were curetted, including the granulating skin surface, and after covering the sutured wound edges with a sterile gauze dressing wet with dichloramin-T, they were all covered in completely by a plaster cast from above the knee to, and including the foot. There being no constitutional or local signs of infection in the meantime, this cast was not removed for five weeks, March 14. The wound was again opened, the line of fracture well curetted and the wound kept wide open by gauze packing. There was not the slightest tendency toward burrowing of pus away from the line of fracture. A cast similar to the others was applied with a considerable opening over the wound for dressings. This cast was removed, May 2, and union seemed firm. The wound was almost healed and showed little discharge. Another cast was applied with an opening in it for dressing the wound. The limb seemed perfectly normal in shape and measurement showed no shortening.

CASE 14.—A huckster, aged 32, Jan. 5, 1922, as he stepped from a moving motor truck weighing about a ton and a half, *slipped on the ice and fell*, one back wheel of the truck passing over both legs. He was brought immediately to the university hospital. Both bones of each leg were fractured, the left in the upper third and the right a little below the middle. Lateral splints were applied to the former and a fracture box to the latter. On the following day, it was observed that the patient could not sleep on account of excessive pain, especially in the left leg and that the foot on this side was becoming cyanosed. A fracture box was substituted for the lateral splints on this leg and an extension cast was applied to the right leg which improved the positions of the fragments that had shown about a half end-on approximation. During the first week the left leg and foot appeared to be becoming gangrenous, but in the succeeding days this condition ameliorated until the gangrene was limited finally to a few toes and the heel. January 22, the extension cast was removed from the right leg. The simple fracture had become infected and pus was exuding through a small skin opening over the tibial fracture converting the simple into a compound fracture. The intern, Dr. H. W. Williams, gave it close attention and used the Carrel-Dakin technic. The infection gradually subsided and, February 9, a cast was applied with a hole for dressing the wound. The treatment arrested any tendency to burrowing of the pus, such as developed in Cases 3 and 6. February 23, the fracture area was curetted and several pieces of bone were removed, the wound being then packed with gauze. April 11, the fracture area was again exposed, three or four *completely loose pieces of* dead bone were removed and the overhanging cortical portions of bone on each side of the fracture were chiseled away so as to expose well the softened fracture line, except in the small portion where the bone surfaces had united. The whole wound was kept as wide open as possible to encourage drainage and healing by granulation.

COMMENT

In thirteen of the fourteen cases, the treatment was that outlined in the preliminary remarks. In six of these thirteen, the extension cast was employed and in seven the operative method, without extension, was used. In three of the extension cast cases, primary healing was obtained and in three secondary healing. In two of the seven operative cases, primary healing resulted and in five secondary healing.

The end-result in every finished case has been excellent, except for moderate internal rotary deformity of the lower fragments in Case 5. This patient was able to follow his old occupation as a motor truck chauffeur, although he has preferred other and lighter employment up to the present time. He did go back to the truck long enough to satisfy himself that he could do this work.

Although other phases deserve attention, the character of the healing with complete closure of the wound and covering it with a plaster cast is most interesting and most deserving of the space and time allotted to the subject. The cases in which primary healing was obtained need no further attention. This may be most advantageously restricted to those in which failure occurred. The outstanding feature of the remaining eight of the thirteen was the absence of the ordinary signs of infection, such as developed in Case 14, which was not compound to begin with. Even in Cases 3, 4, 5 and 6, pain, redness and edema were conspicuous by their mildness or absence. In Case 5, the greatest interest attaches to the effect of the extension, which immediately produced an anemia of the skin and was followed by necrosis of the corresponding area of skin and subcutaneous tissue and this by slow separation of the necrosed tissue and prolonged suppuration. But there was at no time severe or positive inflammation of the surrounding living tissue. In the midst of this suppuration, with a liberal use of tincture of iodin for disinfection, the Parham-Martin bands were applied and well tolerated for nine weeks. Some burrowing of pus occurred, but was by no means extensive.

The most interesting individual case was Case 9, the developments in which were responsible for the unusual course pursued in Cases 7, 10 and 13. Had they followed instead of preceded Case 9, Cases 3, 4 and 6 might have been treated as Cases 7, 10 and 13. There was no sequestration of bone nor any burrowing of pus in the latter three. My own feeling is that mobility at the seat of fracture was responsible for the sinuses in these and might readily have prevented primary healing in Cases 3, 4 and 6, although the drainage tube in Case 3 may have been responsible. I am inclined to attribute the delayed union largely to such mobility. The importance of it in the breaking down the wound technic after the open treatment of fractures has probably not been sufficiently appreciated. Muscle contraction very likely is capable of producing such mobility, even when the limb is immobilized in a plaster cast, extending far above and below the seat of fracture. In not a few cases of simple fracture of the shaft of the femur in which plating has been performed, *a firm close cast, applied from the chest to, and includ-*

ing, the foot, and primary healing obtained, the roentgen ray has later showed the plate lifted from the bone at one end and the screws obviously loose In my opinion, the mobilizing effect of muscle contraction on the fragment ends is the most likely explanation of this condition

Since the completion of this paper I have operated on two patients with compound fracture of the middle of the humerus, using the tincture of iodin technic The first was a woman, about 55 years old, who was knocked down in the street by an automobile, March 14 After one week's unsuccessful attempt by a physician to correct the deformity, during which time the wound was drained by a piece of rubber dam and a tube, I plated the fracture March 21, introducing a drainage tube in the lower angle of the wound The dressings were not changed for nine days when the tube was removed and the wound redressed without drainage All dressings and splints were removed finally at the end of six weeks and two days, when bony union seemed to be firm, as determined by palpation and the roentgen ray

The second patient a boy, aged 10 years, fell from a height of about 18 feet (5 5 meters), May 13, 1922 The fracture was plated on the following day and the dressing applied then has not been removed since When I left home, March 21, seven days after operation he was very comfortable and had not shown any signs indicating infection of the wound

CONCLUSIONS

1 It is probable that most compound fractures of the leg are made compound by the protrusion of a fragment end through the skin, and that, consequently, the associated wound cavity is primarily free of infection except for that introduced by contact of the usual small wound surface and the protruding fragment end with adjacent objects, such as soiled clothing, dirt and other foreign bodies

2 The ordinary aseptic technic to prevent the introduction of more infection and the thorough swabbing out of the entire wound cavity to overcome the infection already present may be justifiably followed by complete closure of the wound without drainage

3 Improvement in results should be sought chiefly in a method of perfectly immobilizing the exactly adjusted fragment ends Success in finding such a method would materially increase the number of cases in which healing by primary union of the soft tissue wound and by primary union of the bone fragments occurs

4 The final results in this group of thirteen cases are much better than could be expected without the early accurate adjustment of the fragments and the cleansing effect of the tincture of iodin

1905 Chestnut Street

ABSTRACT OF DISCUSSION

DR. F B ST JOHN, New York As Dr Thomas has said, the leg is the most common site of compound fracture He further states that the ideal treatment is that which avoids suppuration and converts the compound into a simple fracture and in this I heartily concur I cannot quite agree that the most important question connected with compound fractures of the leg in general is to determine whether the wound and fracture are caused by direct or indirect violence It would seem to me of equal importance to determine the extent of injury to skin soft parts and bone and the probable amount of contamination, whether it be due to an external object directly causing the injury or to soil clothing or skin, and by extent of injury is meant the amount of devitalization of bone fragments or soft parts In the consideration of the type of compound fracture with which Dr Thomas deals we assume a relatively small wound made by the bone with the minimum amount of devitalization of bone fragments and soft parts with in the usual case, a relatively small amount of contamination but it is not always the case in compound fractures of the leg caused by indirect violence, and this should be emphasized Any rational form of treatment which adequately obtains and maintains reduction is desirable and in general, the simpler the fixation apparatus the more desirable it is The second principle viz, to combat infection the result of contamination already acquired and to prevent the introduction of any more, is of equal importance and I would add the prevention of dissemination of already acquired contamination by careless examination or unnecessary manipulation of parts In my experience it has been unnecessary to resort to the open operation for obtaining and maintaining reduction in this type of fracture as we have found that overhead suspension with traction has been satisfactory We also use simple molded plaster splints including the foot and extending well above the knee, with wide fenestration at the site of the wound In rare cases which do not respond to an intelligently applied closed method temporarily maintaining reduction by internal fixation especially a plate with screws never wire bands may be desirable but should be applied only by a surgeon with wide experience in successful operative bone work The open operation with internal fixation adds an unnecessary element of risk especially with primary closure We not infrequently employ partial or complete secondary closure of these wounds as when the bone is actually exposed, and after the immediate danger of infection has passed Obtaining and maintaining reduction by well applied external means without primary suture I believe to be the safest form of treatment especially in the hands of the average surgeon, and it must be remembered that it is he and not the specialist who treats the great majority of the usual compound fractures of the leg

DR FRED W BAILEY St Louis It has been a question in my mind whether the suggestion of Dr Thomas is a distinct improvement Experience of course, is the best teacher My experience with simple compound fractures due to indirect violence and such cases as he reports, is that they are by far the least troublesome I agree with him in the necessity of getting to these cases early before extraneous infection has taken hold and of careful preparation of the field, surgical cleanliness and the removal of all devitalized tissues after careful preparation of the field I agree with him in the value of aiming and holding in position the fractured end and in the main with internal permanent fixation in selected cases Mobility though slight, at the fracture site, such as often occurs in a cast with considerable padding offers less hope for complete primary union Sterilization of the wound and surface is a prime essential Pure iodin followed by alcohol may possibly do harm while it may control infection brought in to a degree, at the same time by further devitalizing the traumatized tissues a condition may be created which is ideal for the increase of infection The best method of treating a recent compound fracture, indirect in type is thorough sterilization of the field as for a major surgical operation apposition of the ends of the bone after the wound itself has been properly cleansed, the use of some good chlorin product, by the Carrel-Dakin method for two or three days, then removal of the drain and observation through a fenestrated cast, we then have the best reason to hope for an ultimately good result As for putting the plate in position in acute fracture, I think it is a thoroughly justifiable surgical procedure in selected cases but such cases are extremely rare I am still too timid to take any compound fracture direct or indirect, close it and place it permanently in a cast depending on the blood picture, pulse and temperature as to whether they are running a benign course

DR. W D COUGHLIN, St Louis I do not yet know how to tell whether I am dealing with a noninfected compound

fracture It is true in many cases that the patient soon converts his small wound into a healed wound and so he has made a simple fracture of a compound fracture, but I have seen so much unnecessary mutilation and so many unnecessary deaths as a consequence of having had these noninfected fractures closed promptly, without drainage, that I am unalterably opposed to it I do not believe that any compound fracture wound should be closed up by any one and every one If Dr Thomas and others like Dr Thomas choose to treat a fracture in any particular way, I have nothing to say, but as a matter of teaching what should be taught to the rank and file of the profession, I think I am quite safe in saying that there are about four fundamental principles to be observed in the treatment of compound fracture one is cleanliness, to remove devitalized tissue I do not understand how in a noninfected fracture there can be very much devitalized tissue The second is reduction, and third the most essential principle in the treatment of a compound fracture, permanent and absolute fixation, if it is possible to obtain it How to make drainage depends altogether on the experience of the operator If he has no experience, the patient will be better treated if provision is made for drainage, but there should be fixation reduction and cleanliness No attempt should be made to close the wound Whether to use a plate at the time of first treatment must be considered, but it ought to be the concensus of opinion of teachers of surgery that the less you meddle with compound fractures the better off the patient will be

Dr Florus F Lawrence, Columbus, Ohio One of the things that was settled years ago was the way fractures healed and the rarity with which osteomyelitis followed compound fractures Infection of the bone is the exception, and generally if there is infection it is of the soft parts The most dangerous type of infection is with the tetanus bacillus When we remember that oxygen is the natural defense against tetanus, it follows that if we cleanse the wound thoroughly with oxygen, or hydrogen peroxid, we may obviate any possibility or danger of tetanus So, in the past twenty years or more, in all compound fractures, I have enlarged the opening when necessary to obtain complete hemostasis and to expose the bone, that it may be sutured or wired or nailed I then flush the wound with a solution of hydrogen peroxid and close it The fact that we have been treating bone does not mean that we must drain A wound of bone unites as readily as a wound in soft parts if we give it the same opportunity, if we suture, nail or wire the fragments, removing those parts that are devitalized, or liable to become necrotic, and, above all, remove seriously damaged soft tissues from the wound and leave the wound protected As Dr Thomas suggested, we can close compound fractures and secure 95 per cent uninfected wounds and primary union of both the bone and soft parts with perfect anatomic and functional results

Dr Isidore Cohn, New Orleans I have been teaching students to treat as many of these fractures as simple fractures as possible Thus I would excise what seems to be devitalized tissue and pack the wound with dichloramin-T, but never suture primarily In all these cases we give antitetanic serum Moreover, after excision of devitalized tissue, we do not put on plates or wire There is a possibility of infection in compound fractures, and in the event of this, plates and screws become loosened and are not as effective as they might be We use the portable roentgen-ray apparatus and immediately reduce the deformity by the McKenna traction table We have been greatly pleased to see end-to end apposition in most of the cases In my own work, it has not been necessary in a single case to put on a plate or use wire or screws or anything of the kind One thing that impressed itself on me was the use of a cast by Dr Thomas for nine weeks without changing If we leave a cast on nine weeks, the muscles will atrophy and contractures will result In order to obtain the best results, it is necessary to change casts frequently, to give baths and massage as well as resistive exercises The nonweight bearing brace diminishes the period of total disability

Dr H W Orr, Lincoln, Neb I must confess to a certain measure of astonishment when I hear certain points with reference to the treatment of fractures debated that have been debated here this morning One or two of the speakers have pointed the way to a solution of our problems, emphasizing the point that we must adhere to fundamentals First of all, we must have anatomic reposition of injured parts at once and must maintain good relationship till healing occurs If we disregard these two things, we have disregarded the principles that are essential for good results To talk of putting metal plates regularly into compound fractures is suggesting something which, in the light of our war experience, no possible percentage of results can possibly justify With our present resources in the matter of proper reposition and immobilization with Thomas splints and such adjuncts as ice tongs and bone pins, it is never very difficult to get proper position and to retain such position until there is good healing

Dr Daniel F Jones, Boston It is undoubtedly true that men of large experience can select the cases in which there may be closure without drainage, but for the average surgeon the closure of compound fractures is a dangerous procedure It is particularly dangerous to close the wound without drainage after putting in a steel plate We must not forget that the great majority of these fractures of the lower leg can be held in position by traction If skin traction or the Sinclair skate cannot be used, sufficient traction can always be obtained by a pin, either over or through the os calcis to hold the fragments in place

Dr William Fuller, Chicago I believe that practically all surgeons agree that the use of any foreign material such as screws plates and wire, in the treatment of compound fractures is a serious mistake, except in very rare instances The first and prime consideration in all compound fractures is the prevention or elimination of infection in the wound So important is this that the bone lesion itself may, with advantage be ignored at first, except for some simple appliance which will prevent further trauma of the soft parts by the sharp ends of the fragments Time does not appear to be valuably spent when we occupy it at this late day in discussing papers advocating the use of foreign material in the treatment of the fractures of the long bones especially compound fractures It is reasonable that the manipulations necessary to introduce foreign material for the purpose of holding a fracture will add a great and serious element of trauma to tissues already damaged in compound fractures Such measures cannot be condemned too emphatically

Dr Dennis W Crile, Chicago I have recently had an opportunity to look up the results in a large number of fractures of the leg The period of disability was five times as long in those cases in which internal fixation had been used as it was in those treated without any sort of internal fixation I think the use of metal fixation is a vicious practice when dealing with compound fractures, with rare exceptions The worst results I have ever seen have been those in which metal has been introduced in the presence of infection We never introduce any metal or foreign substance into any compound fracture

Dr T Turner Thomas, Philadelphia I laid before you what I had been doing with compound fractures of the leg, the why of it and the results Can any one show where internal fixation has done damage? There has not been a single case in which the fear of infection concerned me Give me a method by which I can absolutely immobilize these nicely adjusted fragment ends and I am confident that I shall show a greater percentage of primary healings than I have reported today To have used a method of continuous extension, in my opinion, would have favored unsatisfactory development and, with drainage, would have favored infection I wanted a method that would give firm fixation of the fragments and as nearly perfect reduction as possible at one sitting, with thorough cleansing of the wound I believe that no one has yet shown better results in a similar number of cases of the same kind Nearly every case had a nearly normal end-result Neither life nor limb was threatened in any case

and I lost no sleep What I have been interested in much more than in these compound fractures is to establish the idea that most fractures of the long bones, including compound fractures, are due to a fall and consequently to indirect violence If this is true then most of these compound fractures are being presented to us with perfectly clean wounds except for what infection the usually briefly protruding fragment and small surface may pick up May not tincture of iodin be trusted to neutralize that? Some one said that he could not tell which wound was infected and which was not No one can But believing in the fracture mechanism I tried out this method of treatment with caution and it worked In the early cases, I kept the wounds uncovered by the cast ready for quick exposure on the slightest indication of infection Continuing experience brought increasing confidence and an increasing desire for perfect immobilization so that the close fitting complete cast was later resorted to and never afterward abandoned I cannot see that I should hold myself responsible for what some one else may do with the method On the other hand it might well happen that in the hands of the average surgeon it would give better results than the methods which have been in vogue In some of the early cases the small amount of pus burrowed persistently for a long time but even in them I had far less trouble than in similar cases treated by open methods Again let me emphasize that the pathogenesis of the compound fracture offered here is an offspring of the general mechanism of fractures and dislocations already mentioned and that they are expected to stand or fall together

THE CHAULMOOGRA OIL TREATMENT OF TUBERCULOUS LARYNGITIS

ROBERT A PEERS M D
AND
SIDNEY J SHIPMAN M D
COLFAX, CALIF

Recently Lukens[1] called attention to the use of chaulmoogra oil in the treatment of tuberculous laryngitis, stressing the relief of pain and dysphagia which followed its use Certainly, any agent which is capable of relieving the distress caused by an actively tuberculous larynx is worthy of the utmost consideration, and should be given a trial

Although the use of chaulmoogra oil has been attended by quite markedly beneficial results in the treatment of leprosy and, by some, is regarded as a specific in this disease, its use in tuberculosis is still in the experimental stage Kolmer, Davis and Jager[2] have shown that the oil has no effect on virulent tubercle bacilli in their experiments on guinea-pigs, using an in vitro-vivo method Therefore, we should not expect the oil to act as an active bactericidal agent in any lesions Voegtlin, Smith and Johnson,[3] in a more extensive set of experiments, arrive at the same negative conclusion and, indeed, in one of their series they state that the treatment of their infected guinea-pigs with chaulmoogra oil may have been actually injurious

In view of these facts, Rogers'[4] note of warning that chaulmoogra oil should be cautiously used, and then only by experts, seems peculiarly apropos

In the Colfax School for the Tuberculous, seven patients were set aside for treatment with chaulmoogra oil These patients were purposely chosen because of the severity of their laryngeal lesions which, with one exception, caused excruciating pain and dysphagia With this one exception (Case 6) they were all febrile patients with far advanced pulmonary tuberculosis, and the prognosis was, therefore, grave The most that was hoped for was the relief of symptoms In all seven of the patients, there was involvement of the epiglottis arytenoids and the cords

The accompanying table shows the duration of treatment, which was carried out after the method described by Lukens with a laryngeal syringe, the pulmonary condition and the symptoms before and after treatment

In these cases the treatment was an average of three injections a week, beginning with a 10 per cent solution of chaulmoogra oil in olive oil for one week, followed by a 20 per cent solution thereafter

TREATMENT AND RESULTS

Case	Duration of Treatment in Weeks	Lung Condition		Symptom Before Treatment			Symptoms After Treatment		
		Before	After	Temperature	Dysphagia	Aphonia	Temperature	Dysphagia	Aphonia
1	7	Right moderately advanced left advanced	No change	100 to 102°	+	+	99.7 to 103.4	0	+
2	6	Right advanced left advanced	Improved by roentgen ray	Normal to 101+	+	Slight	Normal to 101+	Slight	+
3	7	Right advanced left moderately advanced	Progressive	Normal to 102+	+	+	100 to 101+	+	+
4	8	Right advanced left advanced	Progressive	99.4 to 101.2	+	+	100 to 103.3	+	+
5	2	Right advanced left advanced		99.5 to 100+	+	+	99.2 to 102.2	+	+
6	6	Right advanced left advanced	Arrested	Normal	0	+	Normal	0	-
7	4	Right advanced left advanced	Progressive	101.8 to 103.6	+	+	102.4 to 104	+	+

From a study of the table it will be seen that in only one instance (Case 1) were the subjective symptoms markedly altered In this case the relief of the dysphagia was remarkable The patient now states that her throat feels much better, and that she swallows more easily Examination reveals a normal appearing epiglottis, small arytenoids, and cords thickened but pale While there is no doubt that the local condition is much better, we must not forget that all tuberculous foci show a marked tendency to remissions and exacerbations, and that the improvement shown in Case 1 may be merely a remission and not necessarily an improvement resulting from local medication

Unfortunately, tuberculous laryngitis is usually secondary to pulmonary tuberculosis, in any treatment the general condition must also be considered In our series of cases, the general condition of two showed no change Patient 2 was receiving other special treatment, and so cannot be considered Patient 6 had an arrested case, and was given the oil merely because he asked for it and no change in his general condition was expected With these exceptions, the general condition of every patient grew steadily worse Their temperatures averaged consistently higher in the afternoons and evenings than they had previously Whether or not this was caused by the oil we are not at present prepared to state, but it was the phenomenon observed

1 Lukens R M Chaulmoogra Oil in the Treatment of Tuberculous Laryngitis J A M A 78 274 (Jan 28) 1922
2 Kolmer J A Davis L C and Jager R Influence of Chaulmoogra Oil on Tubercle Bacillus J Infect Dis 28 265 (March) 1921
3 Voegtlin Carl Smith M I and Johnson J M Therapeutic Value of Chaulmoogra Oil and Its Derivatives in Experimental Tuberculosis J A M A 77 1017 (Sept 24) 1921
4 Rogers L Successful Treatment of Leprosy by Chaulmoogra and Other Oils Practitioner 107 77 (Aug) 1921

Indeed, in Case 1, in which the larynx itself showed such marked improvement, the temperature fell an average of 1 degree F shortly after the oil was discontinued

It should be stated that, in general, the patients said that their throats felt somewhat better after each treatmen Except in Case 1, this was transitory, however, and in two cases, 5 and 7, injection of the superior laryngeal nerves was necessary to relieve the pain

CONCLUSIONS

1 Intralaryngeal applications of a 10 to 20 per cent solution of chaulmoogra oil in olive oil may relieve the dysphagia of an advanced laryngeal lesion entirely, but such relief has followed its use in only one out of our seven cases Slight temporary relief occurred in every case

2 On the other hand, the general condition of a febrile patient may, possibly, be unfavorably influenced by such treatment

3 Caution should be used in the laryngeal treatment of tuberculosis with chaulmoogra oil until more accurate data are in our possession concerning its local and general effects

---

CHAULMOOGRA OIL IN THE TREATMENT OF TUBERCULOUS LARYNGITIS

FRANK L ALLOWAY, S B, M D
AND
JAMES E LEBENSOHN, M S, M D
CHICAGO

Since the publication of Lukens' paper [1] on the use of chaulmoogra oil in tuberculous laryngitis, we have introduced this treatment in the Throat Clinic of the U S Veterans' Hospital, Maywood, Ill Of the patients in this hospital, from 300 to 400 are suffering from pulmonary tuberculosis in some of its various stages In the last four months, forty cases of tuberculous laryngitis were selected for treatment with chaulmoogra oil Our technic differs from that of Dr Lukens only in these respects A special laryngeal syringe is used, the patients are treated daily, and only the 20 per cent solution of chaulmoogra oil in liquid petrolatum is employed

The cases handled fall into four groups

GROUP 1

The largest number treated were those with distinct but not extreme laryngeal lesions These patients had generally been hoarse for months previous to treatment, and had various degrees of discomfort, ranging from a vague sense of pain referred to the throat to definite dysphagia In these cases the symptoms were controlled by the intralaryngeal injections of chaulmoogra oil, though in the severer cases some vestige of discomfort maintained itself The dysphagia is often relieved in a few treatments, but the condition of the voice has been found to be generally but slowly affected

One remarkable case of this group should be cited

J J S had dysphagia and hoarseness for more than six months His general condition was fairly good, but his throat caused him much distress The first attempts at swallowing were exquisitely painful, with excruciating radiations to the ears After the first few swallows the acts of deglutition became somewhat more tolerable The objective findings consisted chiefly of patches of ulceration and infiltration involving the posterior two thirds of both cords, pale infiltration of the aryteno-epiglottidean folds, particularly the right, and sprouting granulations in the interarytenoid region This case was the "chorditic" type of tuberculous laryngitis, in which the arytenoids had become secondarily involved For the first three days of the chaulmoogra oil treatment the patient could notice no change On the fourth and fifth days, improvement was admitted He remarked then that his voice felt stronger and clearer On the eighth day he felt entirely free from discomfort, his appetite had greatly improved, and he spoke without effort Since then his lesions have progressively resolved, and his laryngeal condition has improved in every way

Some cases that at first failed to respond satisfactorily to the chaulmoogra oil treatment went along excellently after one or two applications of Lake's pigment [2] had been given and the chaulmoogra oil treatment continued Control of pain was secured in moderately advanced laryngeal lesions even in cases of advanced tuberculosis that went on to a fatal issue Occasionally the anodyne effect of orthoform had to be used as an adjuvant In none of these cases was cocain used

GROUP 2

The second group of cases included those of early tuberculosis in which the laryngeal symptoms were only a subjective sense of tickling or irritation in the throat, associated with slight hoarseness or weakness of the voice The physical signs revealed by the laryngoscope were slight These cases often cleared up surprisingly after a few treatments Occasionally the pain would recur after the treatments had been discontinued, but would then be as quickly controlled as originally

An interesting case was one of pachydermia laryngis Hoarseness and weakness of the voice had extended for many months With the first few treatments a remarkable improvement in the voice occurred A further strengthening of the voice took place after tonsillectomy The case was pronounced nontuberculous by the medical department

GROUP 3

The third group included those of advanced tuberculosis with advanced laryngeal lesions, that had previously not been benefited by the usual treatments Chaulmoogra oil likewise was not able to afford them any lasting comfort The dysphagia complicated their other miseries till the inevitable end

GROUP 4

Chaulmoogra oil treatment was also carried out in cases of chronic laryngitis dependent on nasal conditions, but without any particularly beneficial results

A few cases of syphilitic laryngitis that were characterized by dysphagia were treated with the oil at the same time that vigorous antisyphilitic treatment was being given The chaulmoogra oil did not seem to be of especial value in these cases

It perhaps deserves mention that a skin lesion of the nose in a tuberculous patient pronounced lupus by the dermatologists was treated with chaulmoogra oil with gratifying results The lesion, when first seen, was of six weeks' duration, and had become progressively more tender and prominent After a week's use of

1 Lukens R M Chaulmoogra Oil in the Treatment of Tuberculous Laryngitis J A M A 78 274 (Jan 28) 1922

2 The formula introduced by Lake consists of lactic acid 50 gm liquor formaldehydi 7 c c phenol (carbolic acid) 10 gm distilled water sufficient to make 100 c c The phenol acts as an anodyne and pain rarely lasts more than a few minutes Cocain is only occasionally needed for the first few applications when the throat is unduly irritable

chaulmoogra oil, all discomfort had disappeared and the lesion showed marked regression The patient is still under treatment

CONCLUSION

Chaulmoogra oil, we believe, should have a definite place in the treatment of laryngeal tuberculosis It is useful in the majority of cases, though in the treatment of laryngeal tuberculosis as a whole it cannot entirely replace the other forms of medication, such as the cocain-epinephrin spray, orthoform, menthol and Lake's pigment, superior laryngeal nerve blocking, epiglottidectomy, etc

Some may be skeptical of the value of chaulmoogra oil, as employed in these cases, because the mechanism of its action is not clear It may be true that the oil has no specific effect, but its beneficial action can be perhaps adequately explained by its detergent, anesthetic and counterirritant properties Barwell[3] says "Intratracheal-oil injections act in the same way (i e like steam inhalations and oil nebulae) in relieving dryness and soreness of the throat, and I have found them very useful in cases of advanced ulceration, reducing inflammation and relieving discomfort" He employed a 1 per cent solution of menthol in liquid petrolatum, but from both theoretical considerations and clinical experience it would appear that chaulmoogra oil should act more efficaciously

Clinical Notes, Suggestions, and New Instruments

A SIMPLE MECHANICAL STAGE

PHILIP REICHERT RAY BROOK N Y

The apparatus here described is a simple efficient and inexpensive mechanical stage for the use of students practicing microscopy

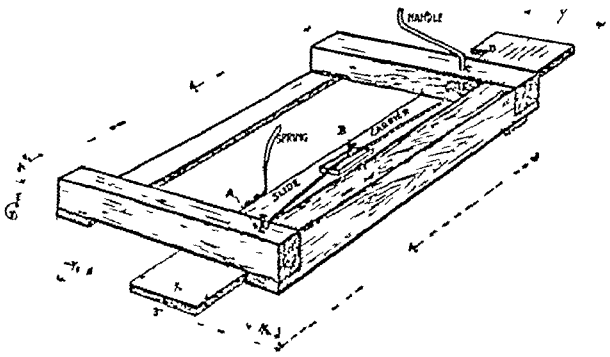
The frame is of wood, well smoothed with fine sandpaper, and glued at the corners Its outside dimensions are 3 by 4 inches On the right cross-piece a vertical hole receives a handle made by bending heavy wire into shape A large opening has been drilled horizontally beneath, making the wire accessible from the side so that a thread may be wound about it by turning the handle

The slide carrier imitates those on the expensive machines It is made of wood 5½ inches long, ⅛ inch thick and ½ inch wide, except for a projection on the right side which makes the width on that side ¾ inch This projection receives the slide, a flat spring cut from thin brass ⅛ inch wide and 2 inches long is placed at a suitable distance on the left to hold the slide against this projection The spring is fastened to the carrier by means of two wire brads, it is wise to hold the thin board in a vise while the brads are being driven so as not to crack the wood

The post *B* is set on a block 1 inch long, ½ inch wide and ⅛ inch thick The left margin of this block must be 2½ inches from the left margin of the slide carrier A rubber band is stretched from this post to the post *A* Placed diagonally as shown, it tends to draw the slide carrier to the left, and at the same time keeps it tight against the frame so that the slide will ride smoothly and not wobble

The action of the rubber band is opposed by a heavy black thread which is fastened to the post *B*, the other end going into the horizontal opening in the right cross piece and winding about the lower end of the handle at *C* The handle should have a radius of about 1 inch It is evident that rotation of the handle will cause the slide carrier to move from left to right or reverse

The frame is mounted on the stage of the microscope and held in place by means of a heavy rubber band or a screw clamp such as may be purchased at any hardware shop When one horizontal excursion is complete, the clamp is loosened and the frame is moved either forward or backward and



Simple mechanical stage

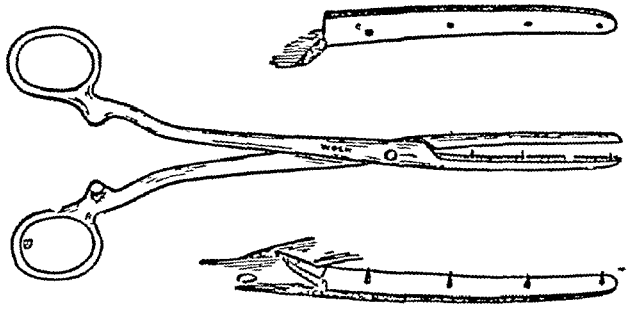
again clamped so as to permit a new part of the field to pass beneath the objective

The cost of the materials is approximately 25 cents, and the apparatus can be easily made in less than an hour In practice it permits steady and accurate control of the movements of the microscopic field

A NEW MUSCLE CLAMP

JOSEPH L DECOURCY M D CINCINNATI

This muscle clamp was adopted primarily for muscle section in thyroidectomy The requirements of such a clamp are to exert a hemostatic action on the vessels of the muscle and at the same time to hold the muscles and fascia in a firm grasp without crushing the tissues The disadvantage of the clamps thus far used, in my opinion, has been that their crushing action not infrequently leads to tissue necrosis and favors infection and adherent scars



New muscle clamp

The clamp consists of a smooth surface with four sharp protrusions as shown The protrusions insert themselves into the fascia and muscles and hold them firm while just sufficient pressure is made from the smooth surfaces of the clamp to close the thin walled vessels without making undue pressure on the other tissues

A Prescription—Filling a prescription is not the same as buying a suit This the customer realizes The man who has been cheated on furniture or wearing apparel has pretty much himself to blame, for he should have some knowledge of what he is buying The same is not true of medicine The customer trusts implicitly, to the druggist, he expects his prescription to be filled by one who knows how to compound medicine and he expects to receive the best drugs—Presidential Address W Gay Clark, Tennessee Pharmaceutical Association

[3] Barwell Harold Diseases of the Larynx Oxford University Press 1907

DISPENSARY SERVICE IN THE UNITED STATES

FIRST PRESENTATION OF DISPENSARY DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The object of this census of dispensaries by the Council on Medical Education and Hospitals is to obtain and tabulate data on the medical institutions for *ambulatory* patients, similar to that already published regarding hospital service in the United States To visualize the work done by all the various dispensaries and clinics requires a simultaneous survey of all of them, including dispensaries that are conducted as outpatient departments of hospitals, independent dispensaries, special clinics, such as tuberculosis, mental hygiene, venereal disease, baby and child hygiene and eye, ear, nose and throat dispensaries, as well as industrial dispensaries and group practices

The number of each kind of dispensaries known to exist in the United States is given in Table 1

TABLE 1—NUMBER AND CLASSIFICATION OF DISPENSARIES IN THE UNITED STATES

General dispensaries		946
Special dispensaries		
Tuberculosis	667	
Venereal disease	487	
Mental hygiene	260	
Baby and child hygiene	566	
Outpatient departments of eye ear nose and throat hospitals	37	
Outpatient offices and stations of the United States Public Health Service	119	
Outpatient departments of orthopedic hospitals	16	
Miscellaneous	53	
	—	2 [illegible]
		3 [illegible]
Industrial (enumeration not completed)		9[illegible]
Total dispensaries known		3 [illegible]43

There are still other dispensaries of each of the several classes that have not responded or about which there are not sufficient data to classify them Particularly is the enumeration of industrial dispensaries incomplete The number of industrial dispensaries has been placed at something more than 400 by some who are in touch with industrial medicine This estimate is very conservative There is evidence to support an estimate that the dispensaries and clinics of all kinds that provide the services of physicians for ambulatory patients, including industrial dispensaries with salaried physicians, would number more than 4,000

As to the amount of service rendered, the general dispensaries that furnished reports handled 3,872,345 patients, who made 11,798,887 visits during the last fiscal year Including a reasonable estimate for the general dipensaries that did not report, these figures would be increased to 4,250,000 patients and 13,500,000 visits In the special dispensaries the average number of patients in each institution is considerably lower than in general dispensaries, but the average number of visits per patient is much larger An estimate based on reports received indicates that the special dispensaries cared for a total of 3,750,000 patients during the year, who in that time made approximately 16,000,000 visits The grand total, therefore, of patients in all general and special dispensaries and clinics would number approximately 8,000,000 and the visits made by them, approximately, 29,500,000 The number of separate individuals using dispensaries and clinics is less than 8,000,000, since allowance must be made for those who patronized two or more institutions during the year

By adding to the special dispensaries enumerated in Table 1 the number of clinics of corresponding kind reported as being held in the general dispensaries, it will be found that there are at least 863 separate dispensaries and clinics for tuberculosis, 793 for venereal diseases, 454 for mental hygiene, 881 for baby and child hygiene, 631 for eye, ear, nose and throat, and 255 for orthopedics

TABLE 2—NUMBER AND WORK OF GENERAL DISPENSARIES BY STATES

State	Population 1920	No of General Dispensaries	Patients Last Fiscal Year	Visits by Patients Last Fiscal Year

On pages 466 to 475 appears a list of 946 general dispensaries or those that provide general medical and surgical care for the ambulatory sick of the communities which they serve The list gives the name and local address of the dispensary and, opposite each, (1) the number of individual patients received last fiscal year and (2) the number of visits made by these patients during the last fiscal year as reported by the

medical director or superintendent. Additional data on special dispensaries are being prepared for later publication in THE JOURNAL, and will be included in a special reprint of dispensary information.

The number of general dispensaries and the work done by them during the last fiscal year are summarized by states in Table 2. Similar data for the fifty largest cities of the United States are given in Table 3.

PHYSICIANS SERVING IN GENERAL DISPENSARIES

On the question as to how many physicians are serving full-time and how many part-time, there were 615 general dispensaries that answered, not including any

TABLE 4.—PHYSICIANS SERVING IN GENERAL DISPENSARIES

	Number of Full time Physicians	Average No Full time Physicians	Number of Part time Physicians	Average No Part time Physicians
459 outpatient departments reporting	1 088	2	7 730	14
157 independent dispensaries reporting	180	1	2 199	14
615 general dispensaries	1 "68	2	9 929	16

of the dispensaries run by the state or federal government. These 615 employ 1,268 full-time physicians, or an average of two for each dispensary, and 9,929 part-time, or an average of sixteen for each dispensary. The answers on this question are summarized in Table 4.

In answer to whether they have separate services for the different departments of medicine and surgery, 429, or 59 per cent., of those answering the question said that they have separate services, and 293, or 41 per cent., said that they have one undivided service for all kinds of cases.

TEACHING IN GENERAL DISPENSARIES

Four hundred and thirty-four dispensaries are doing systematic, organized medical teaching. Their replies are summarized in Table 5.

Of the 637 hospitals approved by the Council for the training of interns, 418 or 66 per cent., have outpatient departments. The figures in detail are shown in Table 6.

TABLE 6.—OUTPATIENT SERVICE IN HOSPITALS APPROVED FOR INTERNSHIPS

	Number of Hospitals Approved	Number That Have Dispensary Service	Per Cent
1 General hospitals	503	338	67
2 State and other hospitals for the insane	28	6	21
3 Other special hospital	106	74	"0
Totals	637	418	66

SOURCE OF FINANCIAL SUPPORT

Reports on the source of financial support received from 651 of the general dispensaries show that 377, or 58 per cent. of those reporting, receive some financial support from patients, 223, or 34 per cent., from endowments, 224 receive gifts, thirty-one get county aid, ninety get city aid and sixty-three get state aid.

The outpatient departments of hospitals are more fortunate than independent dispensaries in having endowments and in getting contributions from patients. Thirty-seven per cent. of the outpatient departments reported endowments, as against 24 per cent. of the independent dispensaries, and 66 per cent. of the outpatient departments collect something from patients, as against 34 per cent. of the independent dispensaries. The majority of outpatient departments that reported

TABLE 7.—FINANCIAL SUPPORT OF GENERAL DISPENSARIES

	Outpatient Departments		Independent Dispensaries		Totals	
	No	%	No	%	No	%
Number reporting financial support	494		157		651	
Source of financial support						
Endowments	185	37	38	24	223	34
Patients	324	66	53	34	377	58
Gifts	154	31	68	44	222	34
County aid	20	4	11	7	31	5
City aid	4,	9	45	29	90	14
State aid	50	10	13	8	63	10
Federal aid	3	6	2	1	5	7

endowments probably meant that the hospital, not the outpatient department, as such, was endowed. In securing financial aid from city, state or federal government, the independent dispensaries run ahead of the outpatient departments. Further details regarding the sources of financial support will be found in Table 7.

SOCIAL WORKERS IN GENERAL DISPENSARIES

Social service workers are employed by 380 general dispensaries, which use 964 salaried and 1,171 volunteer workers, or a total of 2,135 Only thirty-nine said that they depend on volunteers entirely to do their social service

TABLE 8—SOCIAL WORKERS IN GENERAL DISPENSARIES

380 Totals	165	1 171		964		862

OBSERVATIONS

Some of the main facts that have been brought to light in connection with the survey are

1 There is a steady increase in the number of patients seeking treatment in general dispensaries

2 There has been an unprecedented increase since the war in the number of special clinics and dispensaries, such as those for tuberculosis, venereal disease, mental hygiene and child hygiene

3 There is great need for individualized study and treatment of dispensary patients, to counteract what seems to be a prevailing tendency to routinization

4 There is need of a closer bond between the outpatient service and the other service of hospitals, and this will be best met by having the hospital and the outpatient staffs identical and by having unified records

5 In the matter of finances there is an increasing tendency to charge nominal fees, thereby placing part of the cost of an institution on the patient

6 A general increase is noted in the use of social service workers to see that patients continue their treatment, and to investigate their social and financial status so as to prevent pauperizing

7 The difficulty of securing satisfactory data is increased by the inadequacy of clinical and office record systems in a large number of institutions

8 There is a great and increasing amount of educational work, especially the teaching of interns, medical students, graduates and pupil nurses

ACKNOWLEDGMENTS

The collecting of data here published, as well as the large mass of information being digested for publication and for reference, has been made possible through the splendid cooperation of superintendents and medical directors of individual institutions, as well as the organized health agencies, both voluntary and governmental, under whose auspices medical service is provided for ambulatory patients

Among the many that should be mentioned are the state, national and local health departments, and various national and state volunteer organizations, together with their branches and others

It is hoped that the statistics here presented, as well as those that are being prepared for later publication, will be of interest and service to all who are concerned with dispensaries

The amount of data, the degree of completeness and the accuracy obtained are indeed gratifying, and it is felt that a basis has been established for the comparison of data that may be obtained by future surveys, which it is confidently hoped and expected will show unprecedented progress in development of dispensaries and the improvement of their services to their respective communities

GENERAL DISPENSARIES OF THE UNITED STATES

SHOWING THE NUMBER OF PATIENTS RECEIVED AND THE NUMBER OF VISITS TO THE DISPENSARY BY PATIENTS DURING THE LAST FISCAL YEAR

Including outpatient departments of hospitals and independent dispensaries that give a general medical and surgical service

Independent dispensaries are marked (†), and *those not so marked* are the outpatient departments of hospitals

Other classifications indicated are (*), outpatient department of hospital that is approved for a general intern training, (**), outpatient department of hospital that is approved for a special intern training, (¶), dispensary that serves employees and community, (*), dispensary that serves employees and their families, (‡), school infirmary

DISPENSARY SERVICE IN THE UNITED STATES

We publish this week statistics based on an extensive survey of the dispensaries, outpatient departments, clinics and other medical institutions having to do with the care and treatment of ambulatory patients The figures are based on reports received from the superintendents, medical directors or other executives of the dispensaries or in connection with governmental dispensaries from the municipal, state or national officers of these institutions The figures, therefore, were obtained from official sources and are reliable Our acknowledgments are due to all who have cooperated toward the success of the survey Valuable assistance was received from the officers of national health agencies, hospital associations and voluntary medical organizations having to do with ambulatory patients Hearty cooperation was received also from several of the state hospital committees

NUMBER OF DISPENSARIES IN THE UNITED STATES

Information is published in regard to 3,243 institutions from which reports were received and which are known to exist Statements from reliable sources indicate that there are several hundred others for many of which the names have been obtained but from which repeated requests have failed to bring reports which would enable us to include them in our published lists Even as we go to press reports from other institutions continue to come in, a conservative estimate indicates that the total number of dispensaries in the United States will exceed 4,000 *Satisfactory information* has not been obtainable from many institutions for the reason that clinic and office record systems are lacking

Of the 3,243 dispensaries listed, 946 are outpatient departments of hospitals or independent dispensaries which provide general medical and surgical service for their patients, while 2,297 are special dispensaries, such as those for tuberculosis and venereal diseases, mental hygiene and baby and child hygiene clinics, dispensaries of eye, ear, nose and throat and orthopedic hospitals, dispensaries connected with industrial plants, and offices and stations of the United States Public Health Service

DISPENSARIES PROVIDING GENERAL CARE FOR THEIR PATIENTS

Statistics published this week deal mainly with the more important group of outpatient departments, or those which provide for the general, medical and surgical care of patients There are 946 of these institutions, including 689 outpatient departments of general hospitals and 257 independent dispensaries A list of these institutions is published in which are given the name and address of each dispensary and its location, the total number of patients cared for during the last fiscal year and the number of visits made by those patients during that time Similar information regarding special dispensaries such as those for tuberculosis, venereal disease and mental hygiene, is being prepared for publication in the near future and the full report of the survey is to be made available in pamphlet form

GENERAL DISPENSARIES BY STATES

One of the tables published gives the distribution of general dispensaries by states Of the 946, New York State has the largest supply, 163, followed by Pennsylvania with 136, Massachusetts with 74 California with 56, and Illinois with 48 In regard to the numbers of patients cared for, New York naturally leads with 1,182 818, followed by Pennsylvania with 537,438, Massachusetts with 268,775, California with 193,920, and Illinois with 169,872 Of the 3,872 345 patients attending the general dispensaries, 2 717,850, or 70 per cent, attended dispensaries in the fifty largest cities In New York, of the 1,182,818 dispensary patients, 958,622, or 81 per cent, are in New York City

GENERAL DISPENSARIES IN THE FIFTY LARGEST CITIES

Table 3 of the statistics shows that, of the 946 general dispensaries 416, or 44 per cent, are located in the fifty largest cities New York leads with sixty-nine, followed by Philadelphia with fifty-four, Chicago with thirty-three, Boston with twenty-seven and Baltimore with twenty-two As to the number of patients cared for, New York leads with 958,622, followed by Philadelphia, with 356,680, Boston, with 189,692, Chicago with 159,493, and Baltimore, with 109,387 Reports from the dispensaries of Seattle and Indianapolis do not give the total number of patients treated during the year

SERVICE RENDERED BY GENERAL DISPENSARIES

The importance of general dispensaries to the public is indicated by the fact brought out in the statistics that these 946 institutions handled 3,872,345 patients during the year who, during that time, made 11 798,887 visits Including a reasonable estimate for the seventy-five general dispensaries known to exist but from which

reports are not received, these figures would be increased to 4,500,000 patients and 13,500,000 visits

SERVICE RENDERED BY SPECIAL DISPENSARIES

Reports received from special dispensaries show that although on the average they cared for smaller numbers of patients at the same time the patients, as a rule, made larger numbers of visits An estimate for the 2,297, based on definite reports which were received from the majority indicates that these institutions cared for a total of 3,750,000 during the year who, during that time, made approximately 16,000,000 visits

The total number of patients in all dispensaries during the year, therefore, was approximately 8,000,000 who, during the same time, made approximately 29,500,000 visits to those institutions

DISPENSARY PROBLEMS

One of the live problems relating to dispensaries is the abuse of such service by patients who are able to employ physicians Investigation indicates that this abuse is not so extensive as has been supposed The problem is being solved by a careful investigation of the financial status of patients, which is being done by many dispensaries through a cooperation with bureaus of charity which keep a register of the financial status of those seeking financial assistance

Another problem is the establishment of a schedule of fees for the various services rendered by the dispensary and varying in accordance with the extent of the services rendered A large number of dispensaries have already established such schedules, but there is no uniformity among dispensaries in the fixing of such charges There is, also, an evident lack of justice to the patient and of economy to the dispensary in the disproportionate charges for different services in the same dispensary, such, for example, as a charge of ten dollars for roentgen-ray examination, with no charge for a Wassermann test The next few years will doubtless see much progress in regard to the fixing of reasonable fees so that a larger proportion of the expense of conducting the dispensary can be borne by the patients

Another problem which in recent years has been given extensive discussion is that of the pay clinics The object of such clinics is to enable patients who cannot afford to pay the fees charged by physicians to secure satisfactory medical and surgical service at lower rates Such clinics will be instruments of great good if they accept only such patients as are referred to them by physicians or who are found, on investigation, to be unable to pay full fees In this way the pay clinic will work in cooperation, and not in competition, with the medical profession

GROWTH IN NUMBER OF DISPENSARIES

The first dispensary on record[1] was established in London, England, in 1696, to provide medical care for the poor The first established in the United States was in Philadelphia, in 1786, the second, in New York, in 1790, and the third in Boston, in 1796 We find no record of any survey of dispensaries having been made until that by the United States Census Bureau in 1910, at that time there were only 574, including both general and special dispensaries An estimate in 1916 placed the number at 900[1] The present survey gives definite information in regard to the existence of 3,243 dispensaries, not including several hundred others in regard to which there appears to be authoritative evidence regarding their existence but from which thus far it has been impossible to obtain reports Including the latter, the total would be more than 4,000

The increase in population in the country has had some influence on the development of outpatient dispensaries, but the chief stimulus, especially in recent years, has been the increasing popularity of the dispensary as a place to secure satisfactory medical service It has been during recent years also that dispensaries have established well-organized medical staffs and have required their prompt and regular attendance In addition to this, there has been an increasing tendency toward the establishment of graduated scales of fees by which those who were unwilling to accept charity at the free dispensaries are more willing to patronize the institutions Another influence leading to the increase in numbers is the recognition by hospitals of the importance of outpatient departments as a means of better serving the people in their communities It is found that many hospital patients during convalescence can secure the necessary follow-up treatment as ambulatory patients of the outpatient departments

THE BLOOD DURING WATER TRANSPORT

The remarkable constancy in the composition of the important tissues and fluids within the organism must excite a never-failing interest in any one who studies the fundamental physiologic processes Regulatory functions are continually being brought into play to secure the uniformity referred to The various adjustments and adaptations evidently acting to secure a proper arterialization of the blood under the changing condition of atmosphere and tissue needs for oxygen have often been cited in THE JOURNAL An equally effective regulation seems to occur in connection with the behavior of water in the body The variations in intake may be very large, the amount and paths of the output may also show large irregularities depending on a number of unlike circumstances, yet in health the water balance of the body seems to result in a distribution of the "universal solvent" that averts undue concentrations or dilutions wherever an opportunity for the intervention of water may arise

No adequate explanation has ever been offered as to how the large quantities of water often consumed can be taken care of without upsetting the normal

equilibrium within the organism Profuse secretion of dilute urine follows the ingestion of liberal quantities of water by mouth As much may be passed in an hour as is ordinarily voided in a day As Rowntree [1] has recently pointed out, the inference is that water is absorbed, the absorption results in hydremia, which in turn brings about diuresis If this reasonable supposition were true, one would expect in the blood pronounced changes, for a time at least, which might become the stimulus for the compensatory kidney functions, just as an accumulation of carbon dioxid in the blood leads to respiratory changes designed to eliminate the excess of the waste product

Studies of the blood during active water transport have yielded discordant results It might be expected that something significant would be disclosed in the extreme types of this movement as they occur in chronic polyuria, in which it is known that from 15 to 25 liters of urine a day may be excreted Yet cases of diabetes insipidus investigated by Christie and Stewart [2] at the Lakeside Hospital, Cleveland, show how trifling the changes in the concentration of the blood plasma, as regards the electrolytes, may be when great changes in the ingestion, excretion and transportation of water are in progress So far as their experience goes, it would seem that it is only in exceptionally favorable circumstances that even minute changes in the conductivity of the serum, a quantity susceptible of being measured to so considerable a degree of accuracy, can be detected with certainty For example, blood specimens obtained immediately before and immediately after a long period of complete deprivation of water (twenty-four hours or more) showed no definite differences in the electrical conductivity of the serum which could be associated with changes in the rate at which water was being absorbed, transported and excreted The same thing was true of the percentage volume of serum Comparison of blood specimens procured within half an hour, and again after five or six hours, after the resumption of water drinking, with the specimens obtained just before or just at the end of the period of water deprivation, also revealed differences in the conductivity of the serum so slight and so inconstant that it was impossible to connect them definitely with changes in the intake of water

These facts do not contradict the possibility of some changes in the relative volume of plasma and corpuscles or in the total volume of the circulating fluid, even though its osmotic pressure and the concentration of the electrolytes remain the same The problem of changes in the tissue water under such conditions, however, looms large Rowntree [3] has described symptoms attributable to "water intoxication" occurring without significant changes in body temperature, edema or marked increases in plasma volume They resemble the symptoms of clinical uremia in many respects, and raise the question as to the possible relation of water intoxication, if any exists, to uremia, eclampsia and epilepsy At any rate, the blood and kidneys no longer deserve sole consideration in the future analysis of the problem of water balance and transport in the organism

A RECONSIDERATION OF AUTOLYSIS AS A VITAL PROCESS

Some years ago the medical literature was full of articles on autolysis, this process was invoked to explain so many unexplained phenomena that it became almost as much of a catchword as "endocrines" now is Attention seemed to be diverted from the subject after a time, and only a few pathologists and biochemists have continued investigating this phenomenon The tumult and the shouting having now faded well away, it is interesting to consider what has survived of it all, and what significance is now attached to autolysis

The importance of autolysis in the disintegration of dead tissues has never been questioned since Martin Jacoby's classical experiments and this function seems now to be established beyond dispute The problem that has more agitated investigators is the part played by autolysis in physiologic processes and in normal metabolism It seems reasonable to assume that a property so well-nigh universal as autolysis must have been developed to meet some more common situation than the removal of dead tissues, especially since the capacity of cells for autolysis varies quantitatively rather closely with their metabolic activity A consideration of this topic by Bradley [1] presents a matured analysis from the biochemical standpoint, and gives us a basis for a new consideration of the significance of autolysis in medicine

As almost inevitably is the case the introduction of new methods has cast a new light on the old problem, and our education in respect to the essential importance of the H-ion concentration in biologic processes has made it necessary to discard much of what had formerly been learned concerning autolysis, and to revalue the rest Wiener, and later Bradley and his associates especially, have shown that autolysis depends absolutely on acidity, for when tissues have their normal H-ion concentration, which is essentially the same as that of the blood, no autolysis can take place Whenever the circulation within a tissue is stopped, whether within the body or on its removal from the body, acidity begins to increase because of continued metabolism

1 Bradley H C Autolysis and Atrophy Physiol Rev 2 415 (July) 1922

under asphyxial conditions, which leads to an accumulation of organic acids that cannot be completely destroyed because of lack of oxygen When this acidity has developed to a certain degree, autolysis begins, and its rate is largely determined by the degree of acidity that develops, the optimal reaction being slightly on the acid side of neutrality ($p_H = 6.0$)

Therefore we are justified in assuming that autolysis may play its part even in living tissues if their acidity ever develops sufficiently, and Bradley is evidently of the opinion that sometimes this must happen, for he attributes to autolysis a role in many pathologic processes, and also some that are essentially physiologic Perhaps one of the best examples is furnished by the changes that follow poisoning with some of the organic halogen derivatives Evarts Graham secured evidence that the necrosis of the liver that may be produced by chloroform depends on the decomposition of the drug within the cell, liberating hydrochloric acid, which kills the cells and is followed by the rapid autolysis characteristic of acute yellow atrophy of the liver, a condition resembling the chloroform necrosis liver The war gases furnished much unwelcome support of this theory, for most of them, such as phosgen, "mustard gas" and chlorpicrin, are organic chlorin compounds which readily penetrate cells and hydrolyze to produce concentrations of acid that kill the cells and lead to rapid autolysis

Numerous atrophies, without such definite necrosis of tissues as in the foregoing examples, may also be attributed to autolysis resulting from an increased intracellular acidity from asphyxia of greater or less degree Atrophy of the mammary gland after lactation is a typical physiologic example of autolysis resulting from diminution of the blood supply Leaving the gland partly distended with milk hastens the atrophy through pressure, which cuts down the blood supply still more After parturition, the mammary glands in some women produce an excessive secretion of milk, and become tense with pressure and often painful This great initial pressure regularly leads to a diminution through atrophy so that within a few days the supply of milk diminishes automatically, and the common practice of bandaging the breasts to terminate lactation depends on a similar principle In general acidosis and in fevers, the loss in tissue mass is correlated probably with acidotic changes within the tissue cells leading to their partial autolysis The wastage in anemias seems also to be related to the decreased oxygen supplied the tissues, causing partial asphyxia, which permits autolysis to produce a new equilibrium between the mass and metabolism of the tissues of the body and their supporting blood and oxygen supply In starvation we have a striking example of slow autolysis by which a very large portion of the proteins of the body is digested and thus mobilized for the use of the more essential organs It is evident that the tissues least subject to autolysis in starvation are those whose blood supply is most assured, the brain and the heart This slow autolysis is probably related to blood supply and tissue acidosis, as in the other cases mentioned The histologic changes of starvation are in many respects similar to those of autolysis Among other observations possibly bearing on the same question are those of Hildebrandt, who found that autolysis in the functioning mammary gland is much more active than in the resting gland, and of Schlesinger, who found that autolysis was at its maximum (in rabbits) in new-born animals, decreasing rapidly in the first few months of life and that in conditions associated with emaciation the rate of autolysis varied directly with the degree of emaciation The very slow generalized atrophies of advancing age are probably also related immediately to a blood supply growing gradually less efficient, and leading to a concomitant decrease in the mass of tissues maintained in equilibrium with it These are only a few of the more obvious examples of physiologic and pathologic processes in which autolysis has a part Every loss of tissue mass that is not merely due to loss of water probably involves this mechanism It is also of corroborative significance that such observations as have been made on conditions that favor growth of cells indicate that for this function an increase in alkalinity is of importance

All the foregoing evidence indicates that autolysis is a phenomenon that is demonstrable only in pathologic conditions, or in physiologic conditions of atrophy, but does not establish that the responsible enzymes either do or do not play a part in normal protein metabolism

Current Comment

IS THE BILE CONCERNED IN PANCREATITIS?

Scientific investigation finds a justification not only in furnishing new information and consequent deductions to enrich our knowledge, but also not infrequently in dispelling long accepted fallacies or superstitions An instance of the latter has recently been offered by the studies of Mann and Giordano[1] on the anatomy and functions of the bile duct The entrance of bile into the pancreatic duct has repeatedly been charged with responsibility for the production of pancreatitis Mann and Giordano have ascertained, however, that the anatomic relation of the biliary and pancreatic ducts at the duodenum in man is such that obstruction at the exit could rarely if ever permit bile to pass toward the pancreas Furthermore, the sphincter is located at a point at which contraction will close both ducts and will not convert them into a continuous channel Even when a reflux of bile into the pancreatic duct is artificially brought about, the infiltration of the pancreas with the sterile secretion of the liver apparently fails to

1 Mann F C. and Giordano A S The Bile Factor in Pancreatitis Proc Soc Exper Biol & Med **19** 353 (April) 1922

produce acute pancreatitis Finally, bile has been found in the pancreatic duct without the corresponding occurrence of the inflammatory reaction Hence, Mann and Giordano assert that we must look elsewhere than to a bile factor for the explanation of the genesis of most cases of pancreatitis

COLOSTRUM AS A SOURCE OF IMMUNE SUBSTANCES FOR THE NEW-BORN

There are evidences of the existence of certain types of immunity in animals—and presumably also in man—very soon after birth The immense advantage of such early protection against bacterial dangers early in life is obvious How it is acquired has not yet been clearly ascertained, but there is no doubt that substances capable of conferring immunity are demonstrable in the blood of the young at a period before it is likely that a new formation of the "immune bodies" could have taken place to any considerable extent Recently the part played by the colostrum in this phenomenon has been elucidated by investigations on cattle at the Rockefeller Institute at Princeton, N J Little and Orcutt [1] found that the blood of new-born calves before ingesting colostrum did not contain agglutinins against *Bacillus abortus,* but that after the intake of agglutinin-containing colostrum the blood acquired a titer related to the agglutinin content of the colostrum Howe [2] has further shown that certain of the blood proteins are missing in the new-born until after the calves have ingested colostrum containing these globulins It now appears that the agglutinins are associated with these globulin fractions of the proteins of the blood and colostrum, and their absorption by young animals tends to support the idea of direct absorption, into the blood of the new-born, of certain protein fractions present in colostrum [3] The mode in which early immunity may be acquired thus becomes evident, and the importance of colostrum in the nutrition of the new-born is emphasized anew

ON GROWING FOREVER

A single strain of connective tissue cells isolated from a fragment, less than 1 cubic millimeter in size, of the heart of a chick embryo by Carrel at the Rockefeller Institute for Medical Research in 1912 has now passed through nearly nineteen thousand generations in vitro The growth of the tissue fragments is as rapid today as at any other time during the ten years, each piece generally doubling its volume in two days If it had been practicable to allow the tissues to multiply to their greatest possible extent, their mass today would be more than that of the sun These facts, taken from a recent account by Ebeling,[4] fortify the conclusion, to which reference has been made in THE JOURNAL on previous occasions, that such cells, like other forms of protoplasm, seem to be potentially immortal Given a suitable supply of food material, the cells continue young indefinitely, provided the environment does not become oppressive, as may be the case when the products of destructive metabolism are not properly removed or when inhibitory substances are introduced Some biologists have assumed that organisms are endowed with a limited capacity to transform energy On this hypothesis, life does not become prolonged beyond the time when the individual's quota of energy has been metabolized, and this is usually represented by the characteristic life span of the species The chick cells have now been carried through multiplications by absorption and transformation of their environmental tissue juices year after year beyond the usual limit of life of chickens Hence it may be assumed that the fibroblasts can proliferate indefinitely without any rejuvenative influences other than food Growing old involves environmental factors

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

CALIFORNIA

Hospital News—Col Charles E Forbes, director of the U S Veterans' Bureau, recently toured California in search of a suitable site for a $3,500 000 tuberculosis hospital for veterans of the World War The proposed plans call for a 500 bed unit and the use of 250 acres of ground Construction work will be started within ninety days following the selection of a site——An addition will be erected at Fabiola Hospital, Oakland at an estimated cost of $200 000——It has been announced by the Sisters of Providence Hospital, Oakland, that a large site has been purchased for a new hospital building which will be erected in a few months at a cost of $700 000——A new industrial building will be erected at the state hospital at Imola and construction work has been started on the workers' cottages The installation of laundry equipment amounting to $10,000 will also be carried out——A new maternity ward will be erected at St Vincent's Maternity Home, Hollywood——The capacity of the Letterman General Hospital San Francisco, division for disabled veterans of the World War, has been enlarged from 250 to 400 beds by order from Washington, D C

CANAL ZONE

Epidemic of Fever—It was recently announced that an epidemic of malaria has developed among Canal Zone employees The Panama *Star* and the *Herald* are quoted to the effect that breeding places of mosquitoes which had been sprayed with oil the year round, are now neglected and 'there are now more mosquitoes on the isthmus than ever before since sanitation days' These same papers state that the Ancon Hospital is overcrowded with malaria patients

CONNECTICUT

Typhoid Carrier on Farm—Through the efforts of the state department of health, cooperating with the local health officers, a man working on a farm in Connecticut has been found to be a typhoid germ carrier Milk has been produced for sale on the farm in question and six cases of typhoid fever have apparently resulted from its use The finding of the health officers is the result of numerous examinations made in the laboratory of the state department of health in New Haven The carrier who had typhoid in 1895, has been prohibited from handling food of any kind for distribution

New Hospital Addition—Work will soon be started on the new buildings for the Newington Home Corporation at Hartford, a state institution for the care and treatment of

crippled children The legislature at its last session provided $200,000 for such buildings Physicians in the city of Hartford donate their services to the institution free——Ground has been cleared for the addition to the New Britain General Hospital at New Britain, which will be erected in the near future at a cost of $500 000 Final plans have been approved and the contracts will be awarded early this month, it was announced The present New Britain Hospital has a capacity of 100 beds

DELAWARE

Organization of Health Board—The board of health of Dover has been reorganized with Dr L August H Bishop as president, Dr Edwin S Anderson vice president, and Herman C Taylor, secretary-treasurer

DISTRICT OF COLUMBIA

Jewish Hospital in Washington—Architect Harry A Brandt of Washington has been retained to draw plans for the new Hebrew Hospital and Home for the Aged to be located at the capital Buildings for the institution will cost $400,000 Two three and four story buildings will be erected, the materials being brick and limestone——The general contract for a new addition to the Children's Hospital in Washington has been awarded to W E Monney of that city The building will be a one-story structure, 36 by 25 feet, of brick construction

GEORGIA

Physician Honored—The board of trustees of the University of Georgia have conferred on Dr Lamartine G Hardman, Commerce, the honorary degree of doctor of science

Marriage Relations Bill—Women of Georgia are leading in the fight in the legislature to promote the passage of the bills to come before the present session of the general assembly, especially the marriage relations bill This measure which all the state organizations of women favor, proposes that the man should be examined before a marriage license is granted but that it is not essential that the woman be subjected to examination

New Activities of Health Board—The Georgia State Board of Health entered a new field of activity for negroes July 3, when it conducted a health institute for the teachers attending the summer session of the Fort Valley High and Industrial School, Atlanta under the direction of Dr Bocker The institute was conducted by local physicians and members of the staff of the state health board in an effort to train the colored teachers in bettering health conditions in their communities Moving pictures and individual consultations were also arranged

ILLINOIS

Meeting of Tuberculosis Workers—Medical, social and financial problems of tuberculosis were discussed at a conference held in Ottawa, July 27-28, under the direction of the Illinois Tuberculosis Association More than 100 delegates, composed largely of trustees of county tuberculosis sanatoriums, field workers, public health nurses and representatives of all the associations engaged in fighting tuberculosis in sixty counties of the northeastern section of the state, attended the conference.

Big Program for Physicians—Members of the medical societies of eleven nearby counties and their families were invited to attend an open meeting and picnic at Lowell Park, Dixon, July 19, by the Ogle and Lee County medical societies The picnic was the largest gathering of medical men held in that section for many years, members of Carroll, Stephenson, Boone, Winnebago DeKalb LaSalle Bureau, Jo Daviess Kane Henry and Whiteside County medical societies attending A baseball match was held between Ogle and Lee counties Dr Julius H Hess, professor of pediatrics, University of Illinois College of Medicine, spoke on 'Newer Phases of the Nutrition of Infants," and other papers were read by Dr Malcolm L Harris professor of surgery Chicago Polyclinic, and Dr Ernest E Irons, associate professor of medicine at Rush Medical College, Chicago

Chicago

Bust of Dr Black for London University—U S Ambassador Harvey at the request of President Walter Dill Scott of Northwestern University, will present a bust of Dr Green Vardiman Black dean of Northwestern University Dental School, who died in 1915, to the London (England) University Dr Black was known as "the father of modern dentistry, and dental pathology and bacteriology"

University News—Dr Frederick Robert Zeit, for more than twenty years professor of pathology at Northwestern University Medical School at his own request has been relieved of active duty in the medical school He plans to spend next year abroad——The Pathological Museum of Northwestern University will hereafter be known as the Frederick Robert Zeit Museum of Pathology——Dr Charles B McGlumphy has been appointed assistant professor of pathology at Northwestern University medical School Dr McGlumphy has been working with Stoerk at the Franz Joseph Spital in Vienna for the past two years

INDIANA

Herb Doctor Fined—A newspaper report states that Leo M Wolf, who advertised himself as an Indian herb doctor, pleaded guilty to the charge of practicing medicine without a license when arraigned in the city court at Lafayette, July 15 Wolf was warned by the court to refrain from further attempts to practice medicine unlawfully, and was fined $35

Poster Contest for Hospital—In order to raise funds to complete the $2 000 000 building fund for the erection of the James Whitcomb Riley Memorial Hospital in Indianapolis, a state wide poster contest has been instituted, the winning posters to be used as aids to collect funds Prizes of $150 in gold and three original paintings by Howard Chandler Christy, Franklin Booth and Frederick Polley will be awarded the winners of the contest

Hospital News—Improvements costing $10,000 will be made at the Marine Hospital, Evansville——The William S Major home, Shelbyville will be remodeled for a city hospital in the near future The home, which is valued at $75,000, was bequeathed to the city for this purpose by William S Major It is estimated that the cost of maintenance will be about $8 000 yearly Provisions for the expense will be made in the tax levy for the city It is planned to open the institution to the public as a hospital by Jan 1, 1923——The campaign for $100 000 instituted for the Deaconess Hospital, Evansville, was oversubscribed $12 250——The new county hospital at Hartford City is nearing completion——An addition has been erected to the Witham Hospital at Lebanon at a cost of $20 000——A county orphans' home will be built at Lagrange The institution will cost $60,000 and will be a two-story and basement structure——Plans have been prepared for a new hospital in Julietta It will be a two-story and basement structure of brick, steel and reinforced concrete construction to cost approximately $135 000 It will be under county control——Plans are complete for a new sanatorium to be erected at Martinsville Six buildings will comprise the new institution. They will be a three-story and basement structure costing $1,250,000

IOWA

Association for the Blind—At the annual meeting of the Iowa Association for the Blind at Vinton a corporation was established to be known as the Iowa Foundation for the Blind The purpose of the foundation is chiefly to raise money to be lent to worthy young blind persons who wish to enter business for which they have been fitted but lack capital

Society News—At the recent meeting of the Iowa Clinical Society Dr Francis A Ely Des Moines was elected president Dr Charles A Waterbury, Waterloo, vice president, and Dr Russell C Doolittle, Des Moines secretary-treasurer——The Polk County Medical Society has decided to hold a three-day clinic, October 17-19, in Des Moines The five excellently equipped hospitals will furnish facilities for demonstrating the cases——Dr Edward L Rohlf, Waterloo and Dr Leonard A West Waverly were elected president and secretary respectively, of the Austin-Flint-Cedar Valley Medical Association recently——Dr John F Herrick, Ottumwa, has been elected president of the newly organized Military Surgeons Club of Iowa

Banquets for Physicians—A dinner and special meeting of the Jones County Medical Society was held in Monticello, July 17, in honor of Dr Harrison W Sigworth, Sr Anamosa Dr Sigworth is now 85 years old and has practiced medicine in Anamosa for half a century——A complimentary dinner was given to Dr Lee Wallace Dean by his former interns recently At this, the first gathering of the men associated with Dr Dean they organized electing Dr Gordan H

Harkness, Davenport, president, and Dr Clark H Lauder, Grinnell secretary ——A banquet was given given 19, in Des Moines, in honor of the seventieth birthday of Dr James Taggart Priestley of that city and to celebrate his fiftieth year of practice Dr Priestley is retiring from practice

LOUISIANA

Radio for Lepers—The Women's Auxiliary, Rollins Post of the American Legion, installed a radio outfit at the Lepers' Camp at Carville, July 4

Personal—Dr Wilbur C Smith will be the new athletic director at Tulane University, New Orleans, as well as professor of anatomy in the college of medicine ——Dr Marion S L Lombard, who for three years has been directing head of the New Orleans division of the U S Public Health Service, was recently transferred to Mobile, Ala, under the department policy to change its directing heads every three years Dr Charles L Williams, who is epidemiologic aide to the state board of health of Louisiana, will succeed Dr Lombard

MAINE

Personal—Dr Leverett Dale Bristol, Winthrop, for four years health commissioner of Augusta and formerly connected with the medical faculties of Syracuse, Minnesota, Bowdoin and Harvard universities, has been appointed professor of preventive medicine and public health in the University of Minnesota Medical School and the University of Minnesota Graduate School of Medicine He will assume his new duties September 1

Hospital News—Plans have been completed for the $45 000 addition to Madigan Memorial Hospital, Houlton ——Construction work has been commenced on the new Sisters Hospital to be erected at Waterville The building will be four stories high and H M Rourke, Lowell, Mass, is the architect of the structure ——It is reported that the Female Orphan Asylum property at Portland will be converted into a hospital Other buildings will be added to the present orphanage and a modern institution developed

MARYLAND

Investigating Board of Physicians Requested for Penal Institutions—The state board of prison control has invited Dr Llewellys F Barker, Dr J Randolph Winslow, Dr Francis Lee Dunham, Dr Anton G Rytina, and Dr Samuel Wolman, to inspect medical and hospital conditions at the Maryland Penitentiary and the Maryland House of Correction and advise the board what should be done for their improvement No complaint is made of the physicians in charge but it is believed that valuable suggestions can be made from outside and improvements which may be proposed will have the weight of authority of men of high standing in their profession

Health Department Plans Station on Eastern Shore—Establishment of a bacteriologic laboratory on the eastern shore is planned by the state department of health, to overcome delays in examination of cultures from communicable disease cases The new station, which will serve as a branch of the Baltimore laboratory, is expected to be in operation by September 1 Under present conditions specimens obtained in tuberculosis, diphtheria and typhoid cases are not returned to physicians on the lower eastern shore in less than three days A site will be sought at some point affording quick transportation to all eastern shore counties Hagerstown and Cumberland, in the western section of the state, have such laboratories

MASSACHUSETTS

Hospital News—The new east wing of the Free Hospital for Women, Brookline, was formally opened, June 16 —— New buildings will be erected at the Lawrence Memorial Hospital, Medford, in the near future, at a cost of $200 000 ——Work will be begun this summer on a new institution for the feebleminded, to be erected by the state at Belchertown ——Plans have been drawn for a new hospital building for the State Infirmary at Tewksbury It will be a brick structure costing approximately $100,000 ——The New England Baptist Hospital at Boston will erect a new addition at an estimated cost of $400,000 ——Appropriate exercises for the laying of the cornerstone of the new hospital building for Holden District Hospital, Inc, at Holden, were held, June 4

Changes in the Faculty at Harvard—Dr Edward P Richardson has been appointed assistant professor of surgery at the Medical School of Harvard University, Boston Dr Reginald Fitz, for the last two years professor of medicine, University of Minnesota, has been named associate professor of medicine Leonard T Troland, for six years instructor in psychology, has been promoted to an assistant professorship Dr Jacques Bronfenbrenner has been appointed assistant professor of bacteriology, Dr Alice Hamilton, assistant professor of industrial medicine, Dr George Shattuck, assistant professor of tropical medicine, Dr David Cheever, assistant professor of surgery, Dr Lloyd D Felton, assistant professor of preventive medicine and hygiene, and Dr James L Gamble assistant professor of pediatrics Dr James S Stone and Dr John Homans have been appointed instructors in surgery, and Drs William H Smith and Frank H Hunt, instructors in medicine

MISSOURI

Home for Dependent Children—Under enactment of the state board of charities and corrections, the state home for dependent and neglected children has been located at Carrollton The home is intended to care for all deserving homeless, neglected and dependent children of the state No defectives are to be admitted to the institution, which will be under the direction of Mrs Reed, matron, and Dr C S Austin, Carrollton physician

Legislative News—The referendum on the medical college bill (Senate Bill No 433) passed by the last legislature, has been denied in a decision by the supreme court, which upheld the finding of the circuit court declaring the names on the petitions in the Fourth Congressional District insufficient The supreme court discovered that there were only four names less than the required number The petitions from the fourth district being thrown out the entire referendum failed, because there were not enough other districts represented to meet the necessary two-thirds requirement The law which now becomes effective permits any one whom the board refuses to license to appeal to the circuit court, and the circuit court is empowered to rule on the question of what shall constitute a medical school of good standing —— A proposal has been introduced in the Constitutional Convention now in session amending the bill of rights by adding the right to administer to the sick for compensation" Another proposal makes it optional for persons to comply with any health regulations to prevent disease A third proposal authorizes the General Assembly to provide means for safeguarding the public health and welfare

NEW JERSEY

Additions to Hospitals—A three-story addition will be made to the Essex County Hospital for Contagious Disease at Soho, Belleville which has already a capacity of 379 beds ——A new nurses home will be erected at the County Tuberculosis Hospital at Allenwood, it is announced ——The board of chosen freeholders of Essex County has authorized the preparations of plans and specifications for additional hospital buildings at Overbrook, Cedar Grove

Physicians to Cooperate on Compensation Charges—The Medical Society of New Jersey will cooperate with the state department of labor in deciding a just rate of compensation for services given to put into effect the amendment to the Workmen's Compensation act (THE JOURNAL, April 15 page 1134) This measure provides for medical and surgical care in excess of the former $50 limit, and hospital care in excess of the same figure in cases in which application for such additional service has been made to the compensation bureau After a conference of the welfare committee of the medical society and the acting director of the department of labor a digest of the law and sample form of report has been issued to every member of the society The digest stipulates that a triplicate report be made by the attending physician one to be sent to the employer of the patient at the time of the accident and two to be given to the department of labor One of these will be sent to the insurance carrier To prevent overcharges for medical services the state medical society will name a physician in each compensation district to pass on the reasonableness of medical bills in dispute These physicians will confer with two other physicians, one to represent the employers and the other appointed by the department of labor Drs John Haggerty Newark, Dr John McCoy, Paterson, Dr Henry B Costill, Trenton, Dr A Haines Lippincott Camden and Dr Samuel Cosgrove, Jersey City, are physicians suggested by the state society for this work

NEW YORK

Personal—Dr George Schwartz, New York, has been appointed surgeon-in chief of the child welfare board The appointment was approved by Dr Royal S Copeland of the board of health Dr Schwartz will look after the interests of 9,000 widows and 30 000 orphans who come under the jurisdiction of the child welfare board——Dr Nathan O Ratnoff, chairman of the American Jewish Physicians' Committee, accompanied by Drs David J Kaliski and Samuel J Kopetzky, New York, sailed July 22, on the S S *Homeric* for Palestine for the purpose of beginning construction of the Medical School of the Hebrew University in Jerusalem—— Dr Harold R Mixsell and Dr George Gray Ward, Jr, New York sailed for Europe July 22——Dunlap P Penhallow, surgeon, U S P H S, New York, has been appointed surgeon in-charge of the Public Health Service Hospital at St Louis——Dr Means S Gregory, Bellevue Hospital, New York sailed for Europe recently, to study the management of mental patients in hospitals of France, Italy and Switzerland——Dr Maxwell S Blieden, Johannesburg South Africa, is in New York for research study, visiting hospitals for this purpose

New York City

Maternity Center Association Plans Nation-Wide Campaign—The Maternity Center Association is publishing a series of twelve 'Talks to Mothers," through which it is hoped to distribute authoritative information on prenatal care among 100 000 mothers in all parts of the United States In the distribution of the pamphlets, the association plans to enlist state and city health departments and nursing and public health associations closely in touch with local conditions

Alcoholic Deaths Increase—According to the records of Chief Medical Examiner Dr Charles Norris, deaths from acute alcoholism in New York this year have increased 27 per cent over 1921 and 89 per cent over 1920 The records show that eighty persons died of acute alcoholism in the first six months of 1922 These records include only those victims who died without medical attention Dr Norris thinks many others attended by private physicians have died from the same cause Poisoned liquor is largely responsible for the increase

NORTH CAROLINA

Feebleminded and the Law—The state psychiatrist and professor of abnormal psychology at the University of North Carolina, Dr Harry Crane recently announced that there are 50 000 feebleminded persons in that state alone, and that 90 per cent of the inmates of the county homes are mentally abnormal Many of these people are producing children, often worse equipped mentally than themselves, who in turn fill the state's institutions The state laws limit the period in which persons may be cared for, throwing the responsibility for the control and care of these people back on the community, which has made no provision to meet a contingency

OHIO

New Hospital Superintendent—Dr Solomon A Hatfield has been appointed superintendent of the University Hospital, Columbus, formerly a homeopathic institution This is the first step toward coordinating work of the University Hospital with the Ohio State University College of Medicine Dr Claude A Burrett, dean of the Homeopathic College, formerly was in charge of the hospital

University Honors Two Donors—Two chairs in the University of Cincinnati College of Medicine, honoring John D Rockefeller and Andrew Carnegie, donors of munificent sums to the medical school, were founded at a meeting of the board of directors, July 19 The professorship in obstetrics will be known as the John D Rockefeller Chair of Obstetrics and the professorship in biochemistry as the Andrew Carnegie Chair of Biochemistry Dr William Gillespie holds the chair of obstetrics and Albert Prescott Mathews, Ph D, is professor of biochemistry

Hospital News—A new hospital will be erected at Cincinnati which will be known as the Alms Hospital Harry Hake of Cincinnati is the architect——A new nurses' home will be erected at the Grant Hospital, Columbus, at a cost of $110 000 It will be a four-story building——A site has been purchased for a new home for the Toledo Sanatorium for the feebleminded The new institution including several cottages, will be erected at a cost of $1,000,000 The owner and physician in charge is Dr James A Belyea——The Protestant Hospital, Columbus, will be enlarged to accommodate 150 beds Money will be raised at once for the project It is estimated roughly that it will cost $300,000 A staff for the hospital will be elected in the near future

PENNSYLVANIA

Hospital News—The cornerstone of the Homestead Hospital Pittsburgh was laid July 28——A comprehensive plan for improvements and additions to various city hospitals to be completed within the next year at a cost of $1,300 000 was instituted recently in Philadelphia, when Director Furbush opened bids in his office for dormitory buildings, to be used by attendants at the Philadelphia General Hospital and the administration building at the Philadelphia Hospital for the Insane at Byberry——The contract has been awarded for the construction of the administration building at the Philadelphia Hospital for the Insane at Byberry The cost of the building is not to exceed $112 351——New buildings including a nurses home, will be erected at the Tuberculosis Hospital Pittsburgh——An addition will be built to St John's General Hospital Pittsburgh Plans call for a three-story brick building costing $65,000

Philadelphia

University to Erect Graduate School—Announcement was made July 26 of the contemplated erection by the University of Pennsylvania of a graduate school of medicine This was made public following the sale of the Medico-Chirurgical Hospital and College properties by the university Some years ago the Medico Chirurgical Hospital buildings and the adjoining properties were transferred by the Medico-Chirurgical College and Hospital to the University of Pennsylvania for the purpose of founding a graduate school of medicine At that time the erection of a new teaching hospital for this graduate school on the campus of the university was contemplated but the prohibitive building prices during the war prevented the carrying out of the original plans

RHODE ISLAND

Poliomyelitis in the State—The state board of health warned physicians July 21 that all cases of infantile paralysis must be reported both to the state board and to the health officer of the city or town wherein the case develops, forthwith on diagnosis Infantile paralysis is spreading all over the state and many cases have not been reported, Dr Byron U Richards secretary of the state board of health, states The Pawtucket Valley and the city of Providence are the present centers of the near epidemic of this disease Fifteen cases and four deaths are reported from Providence

SOUTH DAKOTA

To Erect Hospital at Minot.—The Trinity Hospital Association has recently been formed for the purpose of founding a 100 bed hospital at Minot The plans have been completed and call for a $200 000 institution A O Fonkalsrud, Ph D formerly of Fargo is the organizer of the project and will be superintendent of the new hospital

TENNESSEE

Hospital News—The contract has been let for the construction of an addition to the City View Sanatorium, Nashville at an estimated cost of $115 000——As a monument to the city and to the fraternity a general hospital will be erected at Chattanooga by the Masons of the district——The Methodists have recently purchased a site in Memphis on which they will erect a hospital the one completed in the spring having been sold to the government——A county sanatorium will be erected at Knoxville There will be a central administration building for offices and nurses' quarters Several cottages for patients will be erected in the grounds——Announcement was made, July 18, by the local antituberculosis association that more than $100 000 had been raised in a recent drive in Knoxville to build a tuberculosis hospital Work will be commenced about September 1

VIRGINIA

Open New Buildings—The two new units of the modern fireproof Marshall Lodge Memorial Hospital, Lynchburg, have been completed and were opened to the public, June 24 Guests of honor for the day were the donors whose gifts made the building possible The hospital represents an outlay of $200,000

WASHINGTON

Graduate Medical Lectureship—The sixth session of a series of lectures given at the University of Washington, Seattle, started July 17 Five lectures each were given by Dr Hobart Amory Hare professor of therapeutics, Jefferson Medical College Philadelphia, Dr John B Deaver, professor of surgery, University of Pennsylvania, and Dr Williams McKim Marriott, professor of pediatrics Washington University, St Louis Single lectures were given by Dr William Englebach, professor of medicine St Louis University School of Medicine, Dr Joseph Colt Bloodgood, professor of surgery, Johns Hopkins University, Baltimore, and Dr Walter Bradford Cannon, professor of physiology, Harvard University, Boston The lectureship was the product of cooperation between the University of Washington, the Washington State Medical Association and the King County Medical Society, and was established in 1916

WISCONSIN

Hospital News—The new addition for St. Saviour's Hospital, Portage, has been completed This includes eighteen rooms for private patients, roentgen-ray rooms and a lecture hall for the sisters——Plans have been completed for a new building for Holy Family Hospital at Manitowoc——A hospital will be erected at the state school for the deaf at Delavan in the near future at a cost of $75,000——Construction work of the $1,350,000 Wisconsin General Hospital to be erected at Portage will be forwarded at once

CANADA

Radium Institute—It is announced by Premier Taschereau, that an institute for radium treatment will be established in connection with the University of Montreal, Quebec Arrangements are now being completed to obtain 1 gm of radium at a cost of $100 000, the amount necessary to commence operations This institute will be the property of the province

Public Health News—In his report to the local board of health for the first six months of this year, Dr C J O Hastings, medical officer of health, Toronto Ont, advises that the infant mortality rate is the lowest in the city's history The rate is given at eighty per thousand births and it is estimated that if there had been a complete registration of births the actual rate would have been sixty-eight per thousand births The general mortality rate for June was 9 9 per thousand as against 8 8 per thousand for the same month last year The half yearly rate was 11 5 as against 12 0 for the first six months of 1921 It is pointed out that over half the deaths registered occurred before the age of 1 month, and it is presumed that these occurred from prenatal causes Cancer claimed the greatest number of victims, forty-eight deaths being registered from this cause in June The death rate from communicable diseases was light During June, 1922, not one birth marriage or death was recorded from the town of Port Dalhousie, Ont

Personal—Dr George D Porter, director of health services at the University of Toronto, represented the Canadian Association for the Prevention of Tuberculosis at the International Union Against Tuberculosis at Brussels, Belgium in July——Prof Herbert S Birkett, dean of the faculty of medicine, McGill University, Montreal, delivered the Semon lecture at the University of London, July 12——Dr Willard F Read Digby N S was recently elected president of the Valley Medical Society——Dr John J Mackenzie, head of the department of pathology in the University of Toronto, is seriously ill in a sanatorium near Gravenhurst Ontario——Dr T J McPhee has been appointed health officer of Namaimo, B C——Dr Charles D McCulloch has been appointed associate coroner for Prince Edward County Ont——Drs John G Fitzgerald and John W S McCullough, Toronto, recently sailed for Europe on the *Montcalm* which ran aground near Quebec City the same day and was not released until two days later, when the passengers were transferred to other steamers

University News—At a special convocation of the University of Toronto June 8 the following honorary degrees were conferred on physicians doctor of medicine Dr Huerner Mullin, past president of the Ontario Medical Association, doctor of science, Dr A D Macallum, doctor of laws, Sir Auckland C Geddes, British ambassador to the United States and former professor of anatomy at McGill University Montreal *His appointment at Washington*, D C compelled Sir Auckland C Geddes to resign from the position of president of McGill University to which he had been appointed—— The degree of LL D was conferred on Dr Clarence L Starr by McMaster University, recently——Dr Perry G Goldsmith has been appointed professor of otolaryngology in the University of Toronto, to succeed Dr David J Gibbs Wishart who resigned recently following thirty-seven years in that capacity——Dr William B Hendry has been appointed professor of obstetrics and gynecology in the University of Toronto, to succeed Dr Benjamin Watson——Dr William H F Addison has been appointed associate professor of anatomy in the University of Toronto Faculty of Medicine——Dr Robert D Defries has been appointed associate professor of hygiene in the University of Toronto and will be acting head of that department until the return of Prof John Fitzgerald from California

PHILIPPINE ISLANDS

Culion Medical Society—It is announced by the *Journal of the Philippine Islands Medical Association* that plans are being made to organize a medical society at Culion, Culion in view of the many physicians stationed there This would be the first unit of the long planned establishment of provincial branch societies of the Philippine Islands Medical Association

Invasion by Chiropractors—It is reported from Manila that numbers of chiropractors have recently arrived in the islands from the United States It is announced that they have bought full page advertisements in the local papers claiming to cure almost every ailment, and that they are attempting to have a bill submitted to the legislature regulating the practice of chiropractic and to establish a chiropractic examining board for the Philippines

Call for Aids at Culion—The following physicians mostly from the University of the Philippines and the Philippine General Hospital, have accepted positions at the leper colony, at Culion following a call for help Drs Jose M Alonzo, Jose Avellana Froilan C Eubanas, Guillermo Fernandez, Santiago Icasiano, Dalmacio Jugueta, Gavina Limcaco, Catalino Nicolas Eloy Pineda, Jose Rodriguez, Jose Samson, Filizberto Solis Felix Valasco, Bonifacio Vera and W Wade. Dr Eliza Roxas is the only woman physician at Culion Plans are being made to construct additional buildings at the colony especially for the segregation of the children of the inmates who are apparently leprosy-free

GENERAL

Thousands of Health Workers Wanted—President Vincent of the Rockefeller Foundation states that, during 1922-1923 the United States will require the services of probably 20 000 health workers At present the number under state, municipal federal and county control is 10 000 Those in the employ of nongovernmental institutions or agencies may number nearly as many more

American Relief Administration—Thirty-three physicians and surgeons, each in charge of one of the Moscow (Russia) Hospitals have united in signing a letter of thanks to Dr William D Nickelsen, medical supervisor of the Moscow district for the American Relief Administration The letter states that when on their last resources, the Moscow hospitals received supplies from the relief administration which have helped to check disease and thanks the administration for its humanitarian activities and willingness to continue the work in the future

Physicians and Druggists Protest to Revenue Bureau—As the result of a protest to the Bureau of Internal Revenue by representatives of the drug and medical professions against the needless and burdensome regulations of the Harrison Narcotic Law and the Volstead Act executive officials of the prohibition department have been instructed by the internal revenue commissioner to "get together with representatives of the drug trade and to do everything possible toward effecting more agreeable enforcement measures This was announced by the counsel for the National Association of Retail Druggists at Washington D C, in July *Vigorous* protests were lodged against the provision requiring the confirmation by the issuing director of all druggists' permits to purchase intoxicating liquor including alcohol it being pointed out that this regulation, if enforced, will invariably cause needless delay to the druggists in their efforts to serve quickly the people with whom they trade Dr George A. Knowles Philadelphia, chairman of the legislative committee of the Medical Society of the State of Pennsylvania, and Dr John N Henry, Philadelphia president of the Philadelphia

County Medical Society, represented the medical profession at the hearing

Bequests and Donations—The following bequests and donations have recently been announced

University of Chicago and Northwestern University Chicago, a total of $200,000 American University of Washington $25,000, by the will of Mrs Ann M Swift of Chicago

St Joseph's Hospital, Syracuse N Y $100,000 for a ward in memory of his wife by George Dohney In addition to this bequest, the hospital receives one ninth or about $150,000, of the residuary estate Among other institutions included in the will are St Mary's Maternity Home the Maternity Hospital and Infants Home, and the Syracuse Free Dispensary

Sheltering Arms the New York Society for Relief of Ruptured and Crippled and the Nursery and Child's Hospital, $50 000 each, Tarrytown Hospital $25 000 St Luke's Hospital, $20 000 New York Association for the Blind the Society for the Relief of the Ruptured and Crippled and the Church Mission each $65,000, by the will of Mrs Mary Kingsland

For the erection of a memorial hospital at Albion Mich, to be known as the James W Sheldon Memorial Hospital, $50,000 by the will of Mrs Leffingwell of Albion

Newton Hospital Newton, Mass, $20 000 by the will of Mrs Juliet Dike of Newton

Grant Hospital of Chicago $10 000 and the German Old People's Home $5 000 by the will of Mr Herman Paepcke of Chicago

University of Virginia Medical School Charlottesville a twenty year endowment life insurance policy for $5,000, by the 1922 graduates from all departments

Hollywood (Calif) Hospital Company $5 000, anonymously

Hygeia Camp for Tuberculosis, New Orleans, $1 400, realized from a tag day

St Joseph's Hospital, Syracuse, N Y Mount Sinai Hospital and Montefiore Hospital New York each $1,000, by the will of Emanuel Jacobson

Yale University New Haven $1 000 for study of the chemistry of the tubercle bacillus by the National Tuberculosis Association

Charleston (S C) County Tuberculosis Association Camp, twenty four beds and equipment from various residents and organizations of Charleston

Intelligence Service of the League of Nations—The International Health Board of the Rockefeller Foundation has entered into a cooperative arrangement with the Health Organization of the League of Nations whereby the board will provide a sum not to exceed $32,840 a year, for a period of five years, for the purpose of maintaining an international epidemiologic intelligence service The board will also provide a sum not to exceed $60,080 a year for three years to put into effect a scheme for the international exchange of public health personnel, to be conducted under the auspices of the health organization of the league Since the establishment, in 1921, of the intelligence service of the health organization of the League of Nations, it has conducted an international epidemiologic information service, keeping all governments informed as to the status of epidemics of typhus, intermittent fever, and cholera, which have been sweeping westward from the famine regions of Russia It has also undertaken to promote the international standardization of vaccines and serums It advises the league in matters affecting health and cooperates with the International Labor Organization in promoting industrial hygiene and sanitary conventions for the control of epidemics It is expected that, by the end of the five-year period, for which funds have been provided by the International Health Board, the epidemiologic intelligence service will have become so efficient and valuable that the various national governments will regard it as indispensable and provide funds for its further maintenance Interchange of health officials will be arranged, not only for observation but for definite periods of service, which will result in actual exchange of experience This system of exchanges will be put into effect first in Europe and may be extended to other countries throughout the world

LATIN AMERICA

Nicaraguan Physician Studying Sanitary Methods—Dr Fausto Robleto of Nicaragua, after spending one year at the Johns Hopkins University School of Hygiene and Public Health, has spent a few weeks in several counties in Alabama, studying field malaria work Dr Robleto is about to sail for his country to put to practical use the knowledge gained in this country

New Medical Society in Peru—Under the name of "Circulo Medico del Peru," there has been organized in Lima a medical society with a membership of more than 100 local physicians The following officers were appointed Honorary president, Dr Ricardo Flores, president, Dr Pablo S Mimbela, first vice president, Dr Guillermo Gastañeta, second vice president, Dr Miguel Aljovin, secretaries, Drs Francisco Graña, Ricardo Palma and Juan Voto Bernales, treasurer, Dr Oswaldo Hercelles, librarian, Dr Ramon Ribeyro, editor, Dr Hermilio Valdizan, and members, Drs J Arce, R Neuhaus, R Eyzaguirre, F Merkel, C Monge and C Carvallo

Personal—Prof Rocha Lima, chief of the Instituto Oswaldo Cruz of Rio de Janeiro, has returned from a trip abroad——The Academia Nacional de Medicina at Rio de Janeiro has conferred the Sampaio prize this year on the pharmacist, P Seabra, for his work on an electric process for producing nitric acid——The *Brazil-Medico* relates further that Dr Barbosa Vianna, was the guest of honor at a banquet, June 23, Dr Aloysio de Castro presiding, just before the latter left for Europe to be the representative of South America in the committee organized by the League of Nations to promote international intellectual relations——Our exchanges mention the arrival at Rio of Prof F Munck of Berlin who addressed the local medical society, with slides, on the diagnosis of tuberculosis

FOREIGN

Society News—The third annual conference of the Gynecologists and Obstetricians of Great Britain and Ireland was held at Liverpool, June 30-July 1——The third annual meeting of the Society for the Prevention of Venereal Disease of England was held in London, June 29, under the presidency of Lord Willoughby de Broke

New Medical Magazine—A new monthly magazine, edited by the Medical Society of Esthonia in Dorpat, containing articles of interest on medicine, surgery and public health has recently been issued The major part is written in Esthonian, with summaries in French and German Some of the articles are written in French and German

Closing of a Sanatorium on Account of Insubordination—The *Policlinico* relates that the sanatorium at Eremo di Lanzo has had to be closed as some of the inmates insisted on managing the place to suit themselves The ringleaders had to be taken away by the police The other inmates were distributed in other sanatoriums, and the establishment was closed

Tuberculin Controlled in Jugo-Slavia—The Postoffice Department has announced that American postal officials have been notified by the Jugo-Slavia government that shipments of tuberculin through the regular mails to that country are prohibited except when consigned to the minister of public hygiene the central pharmaceutical and sanitary depots and bacteriologic institutions

Scientific Congress—The Flemish scientific congresses will be held at Bruges, Belgium July 30 August 7 An exhibition of medical and surgical instruments and of scientific books will be held at the same time Many eminent scientists and physicians will deliver lectures on scientific and medical subjects, more than eighty communications and lectures being announced

Graduate Course in Crime and Punishment—The first graduate course in Crime and Punishment held the last two weeks in May at the University of Birmingham, England, has been pronounced a success The course consisted of six lectures in each of the three subjects mental defects, insanity, and crime and punishment Dr Maurice Nicoll gave two special lectures It is hoped to repeat the course next spring

Prize for Essay on Infant Mortality—The National Baby Week Council has approved the offer of the London *Daily News* of 100 guineas (about $500) for the best essay of 2,000 words dealing with the problem of the excessive mortality of boy babies Awards will also be made to the statutory maternity and infant welfare committees of the districts which effect the greatest reduction in the boy baby death rate within the next twelve months

Degree in Medical Radiology—The *Journal de Radiologie* of Paris states that the medical faculty of the University of Toulouse, France, has decided to organize a course in electrology and medical radiology and will present a diploma to the graduates Paris was the first French university to organize a course in radiology but this is the first in France to include electrology, although electroradiology is a single, indivisible study, at least during the first part of the course

The Centennial of the Brussels Medical Society—The hundred years of work of the Societe des Sciences Medicales et Naturelles of Brussels was reviewed at the centennial celebration on June 22 The president remarked that we must not smile at the errors of the past, as who knows what the future may do to our own beliefs, adding that the responsibility of the physician has been immeasurably enhanced by the immense progress of science The acting president of the society is Professor Bordet, who has contributed much to our knowledge of hormones and fixation of complement tests

Sanitary Reorganization in Spain—The government has introduced a bill for the prevention of avoidable diseases The bill provides for the compulsory notification of communicable diseases, enforcement of preventive measures, especially as regards tuberculosis, leprosy, venereal diseases malaria and infant mortality, investigation of any undue mortality, safe water supplies, creation of food and hygiene laboratories, industrial sanitation, school hygiene, and the appointment of sanitary inspectors The present public health law in Spain goes back to 1855 and it is considered out of date

British Medical Association—The ninetieth annual meeting of the British Medical Association was held in Glasgow Scotland, July 25-28 under the presidency of Dr David Drummond, Newcastle-on-Tyne Sir William Macewen, Glasgow, was elected president for the year 1922-1923, and Mr Charles P Childe, F R C S, Southsea is president-elect for the annual meeting to be held in Portsmouth in 1923 A pathologic museum was organized for the meeting in the anatomic department of the University of Glasgow A public health exhibition was also held by the Corporation of Glasgow during the session

The Chalmers Library—The library of the late Dr Albert J Chalmers formerly director of the Wellcome Tropical Research Laboratories (Sudan), has been presented by his wife to the Royal Society of Medicine The Chalmers Library was formally opened June 23 There are about 1 800 volumes in all, which includes volumes printed before the end of the fifteenth century and others in the sixteenth and seventeenth centuries There is the first printed edition of Celsus *De Re Medicina* (1478) a complete collection of the writings of Culpeper, a copy of *De Contagione* by Fracastorius (1546), Turner's *Greate Herball,* printed in Cologne in 1568 and several fine herbals including a copy of that issued by Fuchs in 1543 and Brunfels in 1546

Personal—A prize of 2,500 pesetas has been presented by the municipal authorities of Madrid to Dr A Navarro Fernandez for his report of his official visit to Sweden, Norway and Denmark to study ways and means to repress the spread of venereal diseases The authorities ordered 2 500 copies of the report to be published for distribution——The Madrid laryngologist Dr Hinojar, was tendered a banquet on his return to his native town, Soria, recently, and the medical faculty of his alma mater Zaragoza, sent a deputation with greetings——The last lecture of Prof Paul Bar of the chair of obstetrics at the Paris medical faculty was rendered an ovation by the crowds who came to bid him farewell on his retirement, having reached the age limit He had declined any formal ceremony, and devoted his lecture to summarizing the results of his own and others' research on the metabolism of fat and sugar in the pregnant——A memorial tablet to the late Prof Raphael Lepine of international fame was recently unveiled at the medical clinic at Lyons——A gold medal was presented by students and other friends to Professor Pentimalli of the chair of general pathology at the University of Naples——The fortieth anniversary of Maragliano's work in the medical faculty at Genoa was celebrated with much ceremony and the foundation of a medical library, June 25, concluding with a reception on board the *Bon Voyage* in the bay after a memorial had been unveiled to two assistants in the clinic killed during the war

Deaths in Other Countries

Dr T Zabala, a prominent psychiatrist of Buenos Aires founder and director of the Instituto Charcot——**Dr Karl Hasse,** formerly professor emeritus of anatomy at the University of Breslau, aged 81——**Dr Heinrich Albrecht,** professor of pathologic anatomy at the University of Vienna——**Dr Julio Matos,** a psychiatrist of Lisbon——**Dr G Correa Barbosa Lima** of Rio physician to the Brazilian Lloyd Line, aged 68——**Dr Guilherme Taylor March,** aged 83 whose services in the city of Nictheroy were so appreciated by the people that he was known as the "father of the poor and a tax-free house was presented to him by the populace——**Dr N A Bergenholtz** of Stockholm

CORRECTION

Schick Test Campaign—Concerning the item with this heading which appeared in the New York news July 15, we are informed that the board of health has started a city-wide campaign, that the number of physicians assigned are twelve, and the number of nurses and nurses assistants, twenty-five The personnel has been divided into two groups the work being carried out under the immediate supervision of Dr M C Schroder in Brooklyn Queens and Richmond, and of Dr A Zingher in Manhattan and the Bronx

Government Services

Hospitalization in Veterans' Bureau

Director Forbes of the U S Veterans' Bureau has submitted for the President's approval sites for two new hospitals one at San Diego or Los Angeles, Calif, and the other at Minneapolis or St Cloud, Minn, or Fargo, N D Returning from a recent western trip of inspection, he stated that he had found the administration of the Veterans' Bureau activities entirely satisfactory in Illinois Colorado, Washington, Oregon, California and Minnesota He declared that the construction of all twelve of the new hospitals for which Congress had recently appropriated $17,500 000 would be under way shortly Assistant Secretary Clifford of the Treasury also announced that during the fiscal year ending, June 30 1922 twelve new hospitals had been erected, with a capacity of 4 051 beds, located in various parts of the country, including institutions for the treatment of veterans suffering with tuberculosis, mental diseases, surgical cases and general cases The hospitals erected under the jurisdiction of the Treasury Department during this period were as follows Lake City Fla, 230 beds, Whipple Barracks, Ariz., 422 beds, Little Rock Ark 257 beds, Fort Walla, Wash, 165 beds Fort Bayard, N M 250 beds, Fort McKenzie Wyo 242 beds Bronx, N Y 650 beds, Edward Hines, Chicago 1 000 beds, Mount Alto Wash 100 beds, Dawson Springs Sanatorium Dawson Springs, Ky, 500 beds, and Excelsior Springs, Mo, 75 beds

Medical Reserve Corps Organizes Society

During the recent encampment of the medical dental veterinary and administrative officers of the M O R C Camp McClellan Ala July 12-26, a temporary organization of the medical section of the Fourth Corps Area was effected Lieut-Col Haride R Hays, Jackson, Miss, was elected president of the organization and Major L H Webb, New Orleans was elected secretary It is hoped to organize a national reserve officers association with the medical section to function in this organization during the national convention of the American Legion in New Orleans in October

Physiotherapy Course for Training of Aids

A course in physiotherapy covering a period of one year, will be offered at the Walter Reed General Hospital Washington D C beginning October 2 The subjects will include all branches of physiotherapy, and in addition lectures on general hospital subjects Credit will be given for previous training in physical education, nursing physiology and anatomy, making it possible to complete the course in six months or less Accepted candidates will be furnished quarters, rations and laundering of uniforms, in addition to $15 a month Graduates will be eligible for positions in the physiotherapy department in army hospitals, and are expected to serve one year

Hospitals for Disabled Soldiers

Locations of two new hospitals for the care and treatment of disabled ex-service men were announced this week by the U S Veterans Bureau, each to cost $1,000 000 The first, consisting of from 250 to 300 beds for mental cases, will be erected at St Cloud Minn, while the other, with a capacity of 500 beds will be constructed at Camp Custer Mich The latter will be built in lieu of the one proposed for the Great Lakes Training Station the President having requested Director Forbes to consider the Michigan location, since Illinois already has several large hospitals

Legislation for Disabled Naval Officers and Men

A measure introduced in the Senate by Senator Shortridge of California provides that all former emergency officers of the World War who served in the Naval Reserve forces and in the Marine Corps Reserve and who have been discharged from the service on account of physical disabilities shall have the same pay, privileges and allowances as regular retired officers of the Navy and the Marine Corps A similar bill for emergency officers of the Army has been before Congress for some time

Foreign Letters

PARIS

(From Our Regular Correspondent)

July 13, 1922

A Legacy of a Million Francs to the Academy of Medicine

Prince Albert of Monaco who died recently, bequeathed to the Academy of Medicine, of which he was an honorary member, the sum of one million francs A like sum was bequeathed to the Academy of Sciences

French Vital Statistics for 1921

The secretary (minister) of labor recently published the official vital statistics for France for the year 1921 It is an unfavorable report from every point of view The number of births is below that of 1920, while the number of deaths has increased, the number of marriages has also decreased The excess of births over deaths, amounting to 159 790 in 1920, or forty-one for each 10,000 inhabitants, decreased in 1921 to 117 023, or thirty for each 10,000 inhabitants

A comparison of the number of births and deaths for the years 1921, 1920 and 1913 is shown in the following table

Year	Total Population	Births	Deaths	Excess of Births
1921	39 209 766	813 396	696 373	117 023
1920	39 209,766	834 411	674 621	159 790
1913	41,476 272	790 355	731 441	58 914

The number of marriages, which reached an unusually high figure in 1920 (623,869), dropped in 1921 to 456,221, but it is still appreciably higher than the number recorded in 1913 (312,076)

An examination of the report brings out the fact that, whereas the number of living births for each 10,000 inhabitants in 1920 was 213, it fell in 1921 to 207, in 1913, it was 191 The relative proportion of deaths has risen from 172 for each 10,000 inhabitants in 1920 to 177 in 1921, reaching about the same proportion that was recorded in 1913—176 for each 10 000 inhabitants

In 1921, sixty-seven of the French departments showed an excess of births over deaths, the total amounting to 127,654, as compared with seventy-three departments in 1920 On the other hand, twenty-three departments showed an excess of deaths over births, the total amounting to 10,631, as against seventeen departments in 1920 The seven departments which, in 1920, showed an excess of births over deaths but in which the balance in 1921 was on the side of the deaths are Aube, Cher, Cote-d Or, Maine-et-Loire, Orne, Seine-et-Marne and Seine-et-Oise In the department of Isere, which in 1920 showed an excess of deaths over births the excess of births over deaths in 1921 was 292 During the year just preceding the war (1913), an excess of births over deaths amounting to a total of 86,768 for fifty-two departments was recorded, and an excess of deaths over births amounting to 27,854 was found in the thirty-eight other departments

The departments in which the excess of births over deaths, in 1921, reached the highest figures are Nord, Seine, Pas-de-Calais, Finistere, Moselle, Bas-Rhin, Seine-Inferieure Cotes-du-Nord, Morbihan, Haut-Rhin, Aisne, Meurthe-et-Moselle, Ardennes and Bouches-du-Rhone In all these departments, with the exception of Aisne Meurthe-et Moselle and Ardennes, the excess of births in 1921 was much less than in 1920

The departments in which the excess of deaths over births in 1921, was highest are Yonne, Var, Gers, Lot, Lot-et-Garonne, Maine-et-Loire Nievre, Hautes-Pyrenees, Seine-et-Oise, Puy-de-Dome, Vaucluse, Cher and Allier In all these departments, with the exception of Puy-de Dome and Allier, the excess of deaths in 1921 was greater than in 1920, three of these departments, Maine-et-Loire, Seine-et-Oise and Cher, had shown an excess of births over deaths in 1920

In 1920 (the figures for 1921 are not as yet available), Germany, exclusive of Wurttemberg and Mecklenburg showed an excess of births over deaths amounting to 623,367, in 1919, the excess of births was 282,230, and in 1918 there was an excess of deaths over births of 299,885 In England, the excess of births for 1920 was 491,781, and for 1921, 390,355

The State Treasury and the So-Called Indemnities of Hospital Physicians and Surgeons

In a great number of cities, the department for the collection of income tax has demanded a report from the administrative departments of hospitals in regard to the amount of "indemnities" received by the members of the medical and surgical staffs, with a view to subjecting them to taxation *Les hopitaux de France*, a medical journal representing the hospitals, protests against this action on the part of the government authorities, and points out that, as the term "indemnities" signifies, the sums so received have not the character of regular compensation or salaries They cannot be compared with the salaries of a professor or a government official Such sums are simply intended to indemnify the physician for the expenses of transportation, for time spent at the hospital and for care given to indigent patients

The Coming Surgical Congress

The thirty-first congress of the Association française de chirurgie will be held in Paris, October 2-7, under the chairmanship of Dr H Hartmann, professor of clinical surgery in the medical department of the University of Paris The subjects to be discussed at the congress are (1) present-day results from bone grafting, by Professor Cuneo of Paris, and Dr Rouvillois, member of the army medical corps, (2) remote results of operations affecting the trunk nerves, by Professor Leriche of Lyons, and Dr Paul Moure of Paris, and (3) technic and results of extirpation of tumors of the large intestine (rectum excepted), by Drs Abadie of Oran, and Okinczyc of Paris

Parliament in Relation to the Campaign Against Alcoholism

A delegation of the Societes antialcooliques françaises was presented recently to the minister of public health, Monsieur Paul Strauss by Monsieur Edouard Soulier, member of the chamber of deputies, and secretary of the "groupe antialcoolique' of that legislative body The delegation informed the minister that the Ligue nationale contre l'alcoolisme will celebrate its fiftieth anniversary by a "semaine antialcoolique, Oct 9-15, 1922 The representatives of the temperance movement requested the minister of public health to restore the annual appropriation of 20,000 francs (suppressed last year) with which to carry on the campaign against alcoholism The general secretary of the Ligue nationale contre l'alcoolisme also asked the minister for his support for the establishment of a home for the treatment of inebriates

Dangers of Intramuscular Injections of Arsphenamin

At the first congress of French-speaking dermatologists and syphilologists, recently held in Paris, the subject of intramuscular and subcutaneous injections of arsphenamin was discussed Some time ago, Sicard stated that, with a given amount of neo-arsphenamin, injected within a certain period of time, intramuscular injections of small doses, given daily or every two days will give a security and a therapeutic activity, together with a degree of innocuousness, that cannot be secured by weekly intravenous injections Syphilologists (Queyrat, Milian, Pinard, Leredde), who deal mainly with recent cases of syphilis, have preferred intravenous injection of large doses, whereas the neurologists are in favor of subcutaneous or intramuscular injections of small doses, repeated and extending over longer periods of time on the ground that they are more effective and that the dan-

ger element is thus to a great extent eliminated The latter form of injections has met with great favor also among general practitioners However, that the risk is really lessened has been questioned by some, and Sicard himself admits that even with this mode of treatment some cases of intolerance arise, as well as with the weekly intravenous injections, namely, when the total amount injected is very high—above 7 or 8 gm, for example Dr Petges of Bordeaux reported a case of grave apoplexy, occurring on the third day, and also several cases of nitritoid crises, which he had had an opportunity to observe following intramuscular injection of arsenicals He holds that the danger from intravenous injections is less grave because it is, as it were, *"plus loyal"* (more manifest) Accidents occur usually a short time after the injection, so that the physician is ready to combat them, whereas, in the case of intramuscular injections, accidents do not manifest themselves until late—five or six hours after the injection—and hence cannot be combated successfully Dr Emery reports having seen grave nitritoid crises *several hours after subcutaneous injection of the arsphenamins* According to Dr Balzer and Dr Marcel Pinard, intramuscular injections may be regarded as harmless in small doses only, beginning with 0 45 gm, the risk becomes the same as with intravenous injections

MADRID

(From Our Regular Correspondent)

July 1, 1922

Bone Vascularization

Professor Lexer of Freiburg recently lectured at the Madrid Medical School on the vascularization of bones He exhibited roentgenograms of bones in which he had previously injected mercury and other opaque materials He was thus enabled to follow the formation of the vascular system in the bones of several mammals and of man at different ages, in health and in several pathologic conditions that involved the bone system A feature in childhood is the marked vascularization of the metaphyses, which contributes to bone formation As growth advances, this metaphyseal vascularization decreases, being replaced by an increase in the nutrient artery, which before was barely perceptible This intense vascularization in the metaphyses explains the abundance of pathologic processes in them Professor Lexer showed a femur amputated for synovial tuberculosis of the knee, in which the enlargements in the branches of the nutrient artery suggested an extravascular leakage of the opaque fluid employed to make roentgenograms, and a histologic study of the specimen demonstrated afterward that this was all due to a tuberculous arteritis The vascular engorgement apparent in some cases of joint tuberculosis shows how useless Bier's hyperemia method must prove in joint tuberculosis

The epiphyseal vessels make their way into the bone with the interarticular ligaments and joint capsules The metaphyseal vessels go in with the capsular and periarticular ligaments, and finally, the periosteal circulation has an enormous importance because the periosteum is essential for bone regeneration When there is no periosteum in transplanted bones, connective tissue replaces bone, but this connective *tissue does not* become bone Some writers have suggested that the vascularization of bone explains by itself the formation of callus in fractures and its changes In ordinary fractures, a part of the bone is nourished by the nutrient artery, which may be more or less damaged but remains permeable, and the other end of the bone receives the metaphyseal, epiphyseal and periosteal vessels Occasionally, however, *the nutrient artery is impaired or destroyed*, and then the vascularization of the distal fragment decreases, causing the formation of pseudarthrosis, owing to the fact that the callus is invaded by connective tissue

The studies of bone vascularization made by Lexer change the modern conception of the reestablishment of bone mobility following fractures It is well known that mobilization of fractured members begins almost immediately Lexer has noted that vascularization is much more pronounced than in normal cases, during a period much longer than assumed, and that this congestion, which indicates a process of activity and regeneration reaches its highest point in the fifth week. In order that this process of bone regeneration may suffer no interference, immobilization must be continued much longer than has been the practice lately Patients must rest for six or eight months, and even longer Lexer has thus succeeded in avoiding pseudarthrosis and osteoporosis, which threatened to cause the disappearance of bone, replacing it with connective tissue Roentgenograms of bones that were losing their outline and opacity when exercised, and that recovered when allowed to rest, were the best demonstration of the correctness of Lexer's view Bier stated that the callus of fractures was formed or stimulated by hormones from the marrow Lexer denies this action by such hormones and attributes the formation of callus in fractures only to bone and periosteal vessels

In concluding he exhibited some recent patients with bone transplantations Most of them were autotransplantations, and one was a homotransplant—a transplantation of a piece of bone from another man who had died in an accident This bone piece 'took," and the roentgenograms made two years afterward disclosed an apparently normal bone Lexer has done wonders in bone transplantation, and many cripples, through his efforts have gained a possibility of life and activity that seemed lost

Disturbances in the Madrid Medical School

The Madrid Medical School has long been a focus of rivalries and jealousies that sometimes come to the surface in a most scandalous form, as happened recently An examining board made up of four professors of anatomy and having Cajal as its chairman decided to recommend Dr Villa, one of the applicants, to fill a vacancy in the chair of descriptive anatomy While they were voting several students, urged by other professors created a serious disturbance, which has been fully exploited in the newspapers and has attracted much attention The board at a previous session, had decided unanimously to recommend Villa for the vacancy, but several professors who were interested in another applicant exercised pressure on the chairman, and when it was his turn to vote, he stated that he did not think that any of the applicants were worthy to fill the vacant chair At that moment, vegetables were thrown at the other members of the board, and they were also called vile names The rioting became so violent that one of the members, Dr Porpetta, the other professor of descriptive anatomy in Madrid, was hit on the head with a cane, and his life was saved only through the action of a policeman, who fired into the air This police interference inside the medical school has displeased the partisans of university independence, although they do not trouble themselves to explain how they would have protected the lives of the board members since the school employees were unable to check the rioters The students have seen how some persons have been appointed professors through political influence, they have seen jealousies prevailing among the teaching staff, they have seen several of the professors come to blows, and, in addition, they have been flattered by certain professors, eager to use them for their personal purposes All this has brought about the greatest scandal ever recorded in the medical school in Madrid

The Prosecution of Quacks

The medical society's report contains a note with regard to some recent prosecutions of persons practicing without a license or engaged in the sale of quack medicines They exposed a man who posed as a brother of a Paris University professor and pretended that he was a collaborator with this distinguished phthisiologist in the invention of an inhalation cure for tuberculosis He opened a sanatorium with the financial aid of several rich merchants, and he attracted a great number of patients, so he employed two registered physicians As the results of the society's work, however, he is now in prison for extorting money from the public by false pretenses The society recently found a diploma mill in Jassy, where for a few thousand lei false diplomas were issued Luckily enough, the establishment was discovered before any of the impostors could enter practice

Fight Against Trachoma

In the newly occupied territories of Roumania, and particularly in the Banat, there are a great number of trachoma cases, chiefly among soldiers and schoolchildren This fact has induced the ministry of public welfare to employ inspectors who will visit every school as soon as possible after the regular school year begins (September 1), examining the eyes of every child for traces of the disease, which, it is hoped, will yield through the efforts of the inspectors Children suffering from trachoma will be kept from school until they have undergone an operation or had appropriate treatment The health department of the board of education will perform the necessary operation and administer treatment without charge A certificate from any reputable physician that treatment has begun will obtain readmission to the child The schoolchildren who are to undergo operation will have to wait their turn at the new trachoma hospitals in Bucharest, Cluj, and Oradia-Mare It is believed that inspection of the children will reveal a great falling off in the number of trachoma cases After the trachoma examination is completed, it is proposed to test the eyes of the schoolchildren for defective vision

When to Allow Morphin in Heart Disease

Dr Elfer, lecturer at the University of Cluj, said, at a recent meeting of the medical society of that town, that there is no reason to look on morphin in its usual therapeutic dose as a heart poison and to consider it contraindicated when a heart lesion is present He states that sudden death may occur after the use of morphin, but that this is just as unavoidable as collapse in chloroform narcosis Great care is, however, necessary when respiratory complications exist, especially if these are acute, and also in acute processes of the endocardium and myocardium Morphin can be employed without fear in purely nervous disturbances, especially in nervous angina pectoris, and in organic angina small doses are indicated The drug should never be withheld in chronic cardiac dyspnea, and in excited and sleepless patients it plays an important role as a sedative before digitalis therapy is begun, as advised by Grossmann in Germany

Lessened Mortality Among Young Children

The health department of the university of public welfare has the following to say regarding the low mortality from contagious diseases of childhood and, as a consequence, the low general death rate for the country Only one death each from diphtheria and measles, two from scarlet fever, and two from whooping cough were reported during June Since the first of the year, there have been twenty-nine deaths from diphtheria, during the corresponding period of 1921, there were 171 deaths from diphtheria Deaths from scarlet fever show a decrease of 47 per cent For whooping cough, there was a mortality of 241 in 1920, and of forty-eight in 1921, a decrease of 80 per cent The gross mortality of the four principal contagious diseases of childhood is strongly on the decrease

Public Disinfection of Houses

Experimental and bacteriologic investigations have shown that the most effective method for use in routine house disinfection is the direct application, by means of an atomizer, of formaldehyd, five parts of a 40 per cent solution to ninety-five parts water, approximately a 2 per cent solution of formaldehyd gas in water to all the surfaces of the rooms A machine devised in the laboratory throws a finely divided stream a distance of 8 feet (2.4 meters) For each 1 000 cubic feet (20 cubic meters), an amount of the solution equal to a pint (0.5 liters) of the 40 per cent formaldehyd is used Tests show 100 per cent of surface disinfection and more than 85 per cent of test objects containing various bacteria Because of the possible presence of protozoa in the houses occupied by smallpox patients, the foregoing process was for a time supplemented by the burning of a new substance, containing sulphur This was finally abandoned because of the lack of means for readily determining its efficiency, and also because of its destructive effect on certain articles of furniture

Campaign Against the Noise Evil

When Americans visit Germany, and more particularly, Prussia, they often give expression to their displeasure over the punctilious paternal control by state and municipal officials of all movements and actions of the general public On one occasion, I heard an American physician express his astonishment on observing that at the railway stations passengers are prevented by the station officials from boarding at the last moment a departing train He stated that such a thing was unheard of in the United States In response to my question as to whether there were not accidents as a result of such uncontrolled freedom of movement, he admitted that there were We may perhaps place in the same category the attempts of the authorities to reduce to a minimum disturbing noises We have police ordinances and court rulings on which the general public may base claims for protection against musical performances before open windows, against immoderate beating of carpets or against prolonged and disturbing use of machines, and many other noises of a disquieting nature Some examples of the application of such ordinances are given by the chief state's attorney Ebermayer, in the current issue of the *Deutsche medizinische Wochenschrift* For example, the proprietor of an ocean beach hotel was restrained from allowing meat bones to be chopped up in his kitchen before 8 a m, on the ground that the noise exerted a harmful effect on the health of nervous frequenters of the resort, who resided near by In another instance, the operation of circular saws in a residence section in which many brain workers resided was prohibited by the authorities From this decision, an appeal was taken to a higher court, and the judgment was reversed, it being urged by the expert witnesses that if the operation of the saws were confined to the periods between 9 a m and noon, and between 4 and 6 p m, the claim that an impairment of health resulted from the inordinate noise could not be estab-

lished and that therefore a prohibition covering all hours of the day was not justifiable It is interesting to note that in the litigation of this case it was brought out that the police power can be invoked not only when the general public is disturbed but also when certain individuals are discommoded, and that it is not of material consequence whether the persons disturbed by the noise settled in the neighborhood before or after the disturbance in question was set up By decisions of the Prussian Oberverwaltungsgericht, judgments holding that a bowling alley may not be opera ed after 10 p m and that musical renditions in a cabaret may not continue after 11 p m were confirmed Another superior court decision, on the other hand brings out certain limitations of police power a claim that certain noises are disturbing cannot be made on the ground that a siesta following a midday meal is disturbed, that the leisure hours after the day's work are broken in on, or that mental work is interfered with by music However that a given noise constitutes a continued disturbance of the night's rest, which is to be regarded as beginning at 10 o clock is a valid cause for complaint The ordinance forbidding prolonged beating of carpets was formerly considered applicable only to health resorts, but according to a decision rendered in 1915 by the Prussian supreme court such restraining ordinances are enforceable in Berlin as well

The Question as to What Medical Fees Foreigners Should Be Charged

More particularly since the outbreak of the war the reproach has been commonly heard in foreign countries that the Germans of the present day are out of tune with the rest of the world, but we have had abundant opportunity of countering with similar charges We are sensible enough to recognize the fact that the reproach may be justifiable in many respects Our critics, however, should beware lest they err by pointing out the mote in the eyes of their neighbors and failing to discover the beam in their own eye In this connection, we have, for some time past, been reproached for charging foreigners higher prices than we charge our own countrymen This applies not only to books and other scientific publications that are commonly exported but also to other German products It applies to the settlements between German physicians and foreign patients sojourning in Germany German physicians are being accused of extortion and rapacity and no attempt is made to consider the actual economic or even the psychologic basis of the situation It is quite generally recognized that the large influx of foreigners into Germany for the summer or a more pro longed stay, brings with it certain economic advantages, in that a considerable amount of foreign money is thus brought into the country On the other hand, even a mere superficial observation of existing conditions reveals that there are great disadvantages associated with the advantages The very limited supply of foodstuffs and industrial products now available in Germany is rendered still less adequate for the home-born, owing to the presence of the large number of foreigners whose demands have to be met The foreigners buy in large quantities because everything is vastly cheaper here than in their own country Thus the scarcity of provisions and other products is caused, in part, by the presence of the foreigners Another disadvantage lies in the fact that the foreigners carry about with them large quantities of the depreciated German currency, which they expend extravagantly, thus bringing about an upward tendency in the prices of all products on which the home-born are dependent If in the hotels of the large cities and the health resorts a charge for board and room of 850 marks ($1 70, at the present rate of exchange) per day is made, or if for a night's lodging even 700 marks ($1 40) is charged it will be admitted that these prices are ridiculously low as compared with the prices charged in the simplest hotels in the United States Is it any wonder that the Germans try to protect themselves, at least in part, against the aforementioned evils by charging foreigners higher prices than they do their countrymen? In the case of the learned professions, another factor of a psychologic nature enters into the case. To a physician for example, it seems degrading if he is called on to accept for a consultation given a foreigner a sum of money which, in the foreigner's native land the elevator boy would not be content to receive as a tip These are some of the reasons why the German physicians have of late been charging foreigners higher fees than formerly One would suppose that Americans, above all others, since they are reputed to take a frank and open attitude toward the realities of life and do not as a rule, allow themselves to be swayed by sentimentalities, would easily comprehend the situation After the explanations here given have been weighed carefully, the action of the executive committee of the Berlin-Brandenburg *Aerztekammer* in supplying all physicians who desire it with the following placard (printed in four different languages), to be hung up in their offices, will be better understood

To Our Foreign Patients In agreement with the conceptions of foreign physicians the physicians of Berlin charge foreign patients from countries in which there has been little or no depreciation of money values the same fees for medical services that they would pay in their home country An exception will be made in favor of such foreigners as have taken up their residence in Germany and are practicing a profession or following their calling here in this country

It is planned to publish a pamphlet which will give the fees charged in foreign lands for various types of medical service A distinction will be made as to whether the patient is in moderate circumstances or financially well situated, also as to whether the service was performed by a general practitioner a specialist or an expert of first rank In this connection, it may be well to mention the following points as brought out in the *Berliner Aerztekorrespondenz* 1 Whenever possible, before service is rendered an agreement should be reached in regard to the fee 2 All bills should be made out in German marks 3 Foreigners who have taken up their permanent residence in Germany and are earning their livelihood here receiving their income direct in the form of German marks will pay such fees as their financial circumstances will warrant The same rule will apply to members of foreign commissions for whom the government is under obligations to furnish free medical service in case of illness

Marriages

RODERICK HOFFMAN SHIPPEY to Mrs Stella B Murphy, both of Long Beach Calif, at Santa Barbara, Calif, July 3

FREDERICK HUBBELL MILLS, Major, M C U S Army, to Miss Alice Lillian Small, at Albany, N Y, July 8

WILLIAM LOWNDES MCDOUGALL, New York, to Miss Mary Alice Thomas of Griffin, Ga, June 20

JAMES EDWIN PURDY, Pittsburgh to Miss Edith Funston Ballentine of Philadelphia, June 24

LOUIS FRANCISCO ROSS to Miss Margaret Grubbs Starr, both of Richmond, Ind July 19

EDWARD JOHN GRAY to Miss Marjory Ramage, both of Vancouver, B C, Canada, July 10

JAMES BEYEL HELLER JR, to Miss Martha Silliman Cole, both of Pottsville Pa, recently

MARTIN L D MEYER, Chicago, to Miss Hortense Schroeppel of Collinsville, Ill, July 25

CHARLES W L JOHNSON to Miss Ella Blackiston Conway, both of Baltimore, July 12

Deaths

Frank Barbour Wynn ⊕ Indianapolis, Medical College of Ohio University of Cincinnati 1885, was killed in a fall on Mount Eanon near Banff Alberta Canada July 17 It is reported that the fall was the result of a cerebral hemorrhage Dr Wynn was born in Franklin County Indiana, May 28, 1860 He was graduated from De Pauw University in 1883 and received his medical degree two years later In 1886 he was made master of arts by De Pauw University From 1886 to 1888 he served as assistant physician in the Ohio Asylum for the Insane, in 1891, he served on the staff of the Northern Hospital for the Insane at Logansport Ind Following this work, he studied abroad and on his return in 1893, located in Indianapolis becoming the first city sanitarian in 1895 At this time also he became professor of medical diagnosis in Indiana University School of Medicine holding the position until the time of his death Dr Wynn was chairman of the Indianapolis Civic Commission in 1910 and was active in civic affairs in Indiana serving as chairman of the Indiana Centennial Commission from 1911 to 1916, and as president of the Indiana Historical Society He was formerly president of the Indiana Medical Society and of his local medical organization In the American Medical Association Dr Wynn served as a member of the House of Delegates in 1913 and 1914, he was secretary of the section on pathology and physiology in 1900 and chairman in 1901 The first scientific exhibit of the American Medical Association held in connection with the annual session was in the name of the Indiana State Association and was organized by and conducted under the management of Dr Wynn This exhibit was presented at Columbus Ohio in 1899 Such an exhibit has been a feature of the annual session since that time and Dr Wynn served as director up to and including 1916 He was elected Vice President of the American Medical Association at the Boston session holding the office during 1921-1922 At the time of his death he was president of the American Alpine Club During the last twenty-five years he spent many of his vacations in mountain-climbing expeditions and he held records for many attempts at scaling the mountains in Glacier National Park Dr Wynn was one of the best loved physicians in his state, and a man of broad community and scientific interests

Philip Francis Harvey ⊕ M C U S Army Denver, State University of Iowa College of Medicine Iowa City, Iowa 1864, Bellevue Hospital Medical College, New York, 1866 joined as assistant surgeon U S Army, 1868 served in the Medical Corps during the Civil War Sioux Indian Wars the Spanish-American War and during the Philippine Insurrection, professor of surgery at the National University Medical Department, Washington D C 1866-1868, retired Dec 4, 1908, member of the Association of Military Surgeons, Society of Foreign Wars and the Society of the Army of the Potomac died June 7 aged 78 Dr Harvey when chief surgeon of the Department of the Lakes in 1905, introduced for the first time in the Army a prophylactic system for the elimination of venereal disease

Isadore N Bloom ⊕ Louisville Ky , Medical School of Harvard University Boston, 1881, professor of dermatology and syphilology at the University of Louisville Medical Department, Louisville Ky , on the staffs of the Louisville City and Jewish Hospitals, served for several terms as president of the school board, member of the American Urological Association, died July 16 at the 'Norways' Sanitarium Indianapolis aged 63

Edward John Bermingham, New York, Medical Department of Columbia College New York 1873, founder and superintendent of the New York Throat Nose and Lung Hospital, former president of the New York Academy of Medicine and of the Society of Medical Jurisprudence, died July 15, aged 69, from diabetes and heart disease

William H Monday, Terrell, Texas, Medical College of Louisiana, New Orleans 1871, member of the State Medical Association of Texas, Civil War Veteran, for several years president of the school board, at one time president of the Kaufman County Medical Association, died suddenly, July 16, aged 79

Edwin R Rasely ⊕ Uniontown Pa , Medico-Chirurgical College of Philadelphia 1891 member of the American Roentgen Ray Society, was found dead in his photographic dark room, accidentally electrocuted July 12, aged 55

⊕ Indicates Fellow of the American Medical Association

Frank W Garrett, Liberty Center, Ind , Medical Department Butler University Indianapolis 1882, member of the Indiana State Medical Association, formerly a druggist, at one time postmaster and health officer of Liberty Center, died July 17, aged 66, from carcinoma

Abner S Crocker, Oklahoma City, Medical Department, University of Louisville 1890 member of the Oklahoma State Medical Association, died at the State University Hospital July 13 aged 54 from a bullet wound in the lung, having accidentally shot himself

Joseph Michael Gallen ⊕ Columbus, Ohio, Ohio Medical University Columbus 1907 formerly instructor of surgery at the Ohio State University College of Medicine, on the staff of St Francis Hospital, died July 11, aged 37, from chronic nephritis

Aaron Hendrick Connett, Great Bend, Kan , College of Physicians and Surgeons Keokuk Iowa, 1878, member of the Kansas Medical Society for several years county coroner health officer and physician, died, July 17, aged 72, from paresis

William P Norris, Salem Va , Louisville Medical College Louisville Ky 1892 member of the Medical Society of Virginia for several years county coroner and health officer of Salem died suddenly, July 23 aged 55, from heart disease

Thomas Venable Bond, Fort Steilacoom Wash , University of Virginia Department of Medicine Charlottesville Va 1905 member of the Washington State Medical Association died June 23 aged 43 from tuberculosis

Hyman Shlappin, Newark N J University and Bellevue Hospital Medical College New York 1910, member of the Medical Society of New Jersey on the staff of the Newark Beth Israel Hospital died July 16 aged 38

William Albert Gartner ⊕ Troy Kan Ensworth Medical College St Joseph Mo 1914 died June 30 at the Missouri Methodist Hospital Association St Joseph, Mo, aged 38 from septicemia following an insect bite

Peter White Cody, Boston, College of Physicians and Surgeons Keokuk Iowa 1882, member of the Massachusetts Medical Society died July 15 aged 64, from the effects of a fall received some time ago

John William McKone, Lawler Iowa University of Iowa College of Medicine Iowa City Iowa 1896 member of the Iowa State Medical Society, died July 16, aged 48, from chronic interstitial nephritis

Louis C Swartzlander, Omaha John A Creighton Medical College Omaha 1906 member of the Nebraska State Medical Association, died suddenly, July 17, aged 39, from heart disease

Henry Green, Yakima Wash (licensed Washington, 1888) Confederate veteran formerly member of the state legislature died July 10 aged 99 from senility

John H Hussey, Eddyville Ky Medical Department, University of Tennessee 1883 member of the Kentucky State Medical Association, died, July 14 aged 61

Lewis Moody, Bremerton Wash Medical Department, University of Illinois Chicago 1900, died May 9, aged 41, from cerebral hemorrhage

George Lewis Day ⊕ Lone Tree Iowa, State University of Iowa College of Medicine Iowa City Iowa, 1895, died suddenly July 20 aged 51

Britton O Watkins, Kingston Tenn Medical Department University of Tennessee 1891 died June 30, aged 68, from pulmonary tuberculosis

Craig Worth ⊕ Mapleton Iowa University of Missouri School of Medicine Columbia Mo, 1906, died, July 16, at Independence aged 42

Samuel D Geissinger, Elmira N Y , Jefferson Medical College Philadelphia, 1877, died, March 14 aged 73, from heart disease

Annetta Kratz, Danboro, Pa Woman's Medical College of Pennsylvania, Philadelphia 1871 died May 28 aged 75

Isaac Newton Wear, Los Angeles (licensed Illinois years of practice), died July 9, aged 70 from heart disease.

Eugenia Julia Reinhardt, Denver, Denver Homeopathic College 1897 died June 30 aged 55 from ascites

W D Penn, Gulfport Miss (licensed years of practice), died June 14 aged 82 from senility

Elmer Elsworth Cowdrick, Cleveland Chicago Medical College 1886 died, June 22, aged 60

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

ETO-SO-ERC

Intravenous Creosote Medication of T M Berry

A circular, signed T M Berry, M D, New Orleans, recommends the intravenous use of "Eto-So-Erc" ("Creosote" spelled backward) for various conditions It reads in part

Dear Doctor From my past ten years experience of intravenous medication I feel justified in calling your attention to the potential effects of Eto So Erc intravenously Eto So Erc is a highly purified form of Beechwood creosote especially prepared for intravenous administration It comes in direct contact and becomes fixed to the pathologic tissue and bacteria

The antiseptic effects are positive

The beneficial effects are rapid and recognized by the patient

The administration is safe and accurate as to dosage

There is no reaction or alarming symptoms

Recommended in the treatment of All stages of pulmonary tuberculosis influenza pneumonia acute and chronic bronchitis pulmonary gangrene or any pulmonary inflammation where you feel a pulmonary antiseptic is desired

Guttmann states that Tubercle Bacilli are destroyed by blood containing one part of creosote in 2 000 and even one half that proportion arrests their development *20 c c* of Eto So Erc gives you *1 to 2000 in a 150 lb man*

Creosote is credited with being of some value in tuberculous infections when taken orally, although even on this point clinical opinion is divided The benefits, according to Sollmann, are to be seen only in early cases of tuberculosis, if the use is long continued and if it does not cause gastrointestinal disturbances It is most probable that any benefits derived may be referred to the local effect on the alimentary canal and on the bronchitis and to the antipyretic action In such cases, the benefits would not be obtained by intravenous injections of creosote such as in the proprietary Eto-So-Erc" In fact, the administration of creosote by other ways than mouth is said to be very much less efficacious (Cushny, 'Pharmacology and Therapeutics")

The argument advanced for 'Eto-So-Erc" in respiratory infections is that "Tubercle Bacilli are destroyed by blood containing one part of creosote in 2000 and even one-half that proportion arrests their development 20 cc of Eto-So-Erc gives you 1 to 2000 in a 150 lb man" This assertion is misleading because the tubercle bacilli in the lungs are imbedded in the tissues and therefore are inaccessible to the creosote As the Council on Pharmacy and Chemistry pointed out in 1915, there is no evidence that creosote excreted by the lungs is in sufficient quantities to have any germicidal action

The formula for Eto-So-Erc is not given, although it is claimed that each 160 m (10 c c) ampoule contains 10 m of creosote, of what the remaining 93 per cent is composed we are not told

To give creosote, a readily absorbed drug, intravenously is irrational and unscientific The claim that "creosote comes in direct contact and becomes fixed to the pathologic tissue and bacteria" and therefore Eto-So-Erc is to be used in all pulmonary diseases, is simply playing on credulity

---

International Health Drive—At the session of the National Conference of Social Work recently held at Providence, R I, Dr George E Vincent, president of the Rockefeller Foundation, in an address stated that the health committee of the League of Nations, the League of Red Cross Societies, international scientific bodies and the International Health Board are in the field Scientific research workers are in constant communication in many national centers, and governments are sending attaches of hygiene into one another's territories Vital statistics on an international scale are being reported more accurately Prompt notification of epidemics is being facilitated, and outposts against plague and other diseases are being stationed and supported.

Correspondence

"THE PLACE OF VERSION IN OBSTETRICS"

To the Editor —I was rather surprised that THE JOURNAL should publish such an unfair criticism of a book as it did of 'The Place of Version in Obstetrics" by Dr Irving W Potter (THE JOURNAL, July 1, 1922, p 64)

First the critic's bias was so great and his erudition so incomplete that he lost sight of the real aims of the book, namely, a more extended use of version and an improved technic He assumes, with the assurance and omniscience of a deity, that Potter is left handed and that that is why he uses the left hand in delivery, while, as a matter of fact, he is right handed in all his work, but has found that the left hand is the best hand with which to make all deliveries when version is employed

The illustrations (Figs 36, 38 and 39) "show awkwardness" *only to the inexperienced eye and to the casuist who* is trying to multiply his own objections in something he thinks he understands while in reality the subject is evidently entirely new to him If your critic ever saw Dr Potter make a version or will try himself to make one as directed by Potter, he will find that the position of the hands, as represented in the cuts, is not awkward, but the most natural one to take and the one Potter chose after making hundreds of versions by the right and the left hand

Again, any man who has made versions knows that the water should be retained as long as possible to facilitate the maneuver, and by breaking the membranes, high up, this is accomplished Therefore, Levret's insistence on rupturing the membranes, low down, at the os is not sustained in the minds of all practical obstetricians' who have learned their obstetrics at the bedside and not at the library table

The stretching or ironing out of the vagina, although practiced by Edgar and other men, is not the technic employed by Potter, and he has called special attention to it because, in his elective version, the vaginal outlet must be dilated thoroughly, under deep anesthesia, before the delivery can be undertaken

So far as bringing down one leg or two legs, Potter has practiced both methods many, many times, and finds, mechanically, that the two legs are the best dilating wedge, notwithstanding Mme du Tertre's recommendations in 1677"

Figure 15 is not a manifest error of art," although the picture, for teaching purposes, is a little exaggerated It has never been shown in any book on midwifery, nor has your critic ever seen such an illustration, and yet the picture is taken from life, and shows that rotation always takes place from right to left or from left to right according to the position of the child, and is shown in the plate and Plate 17, as the body descends

His criticism as to the indications for version, which are not defined by Potter, is fairly well taken, and in this matter honest men can differ in their practice and conclusions Potter never uses forceps except on the after-coming head, and until it is proved, in the hands of other men, that his practice is more dangerous to mother and child, the question must be left in statu quo

Dr Potter was honest when he said he never broke a bone but once in a living child He does not claim that he does not have intracranial injuries, but he believes that they are less in his practice than in that of other men, a point that again must be proved by further reports

Because a book is small and simply a reprint of journal papers is no reason it is not worth reviewing, and particularly, since it contains a practice, although revolutionary, that is gradually being accepted, in a more or less modified way, by many of the best obstetricians in the country Dr

Potter is certainly teaching a new method in the delivery of the shoulder and arm and many other points which are brought out in the text of his book, if read by an open minded, qualified, practical obstetrician

No matter how much we may differ from Potter in his general use of version, he has demonstrated that version is not as dangerous as we were taught to believe, and should be more often employed, and secondly, the men who are practicing this method say that it is a great advance over any other method previously practiced by them, even if it be something old, as is your critic's contention A just and fair criticism of a book is what all fair minded men look for, and especially in an association journal

The history of version was compiled by one of the most thorough and reputable medical abstract companies in this country, and surely their facilities and combined intelligence ranks with your erudite critic, and they would not have slighted any great authors in the past to make it appear that Potter "de novo originated his present ideas of podalic version"

H E HAYD, M D, Buffalo

[The letter of Dr Hayd was referred to the reviewer of the book He replies]

Since reading Dr Hayd's comments on the review of Potter's book on "Version," I have reread the volume in an endeavor to see the text in the light he tries to cast on it but my views are unchanged by the critical inspection If any misstatements of fact had crept in I would gladly correct them, but even if corrections were possible, the basic views expressed would be unaltered—namely, it is dangerous teaching that it is as safe routinely to deliver all women by operation as to await physiologic labor As clearly as I can see from his meager statistics, he had 0 78 per cent of his patients spontaneously delivered it is not definitely stated, but we are left to surmise that these nine women delivered themselves before his arrival 82 per cent. of his 1,130 cases in his last report were delivered by version, and if version was impossible, then 8 8 per cent had cesarean sections some 7 per cent more had some other operative procedure employed for extraction, and why these last eighty-three patients were not subjected to cesarean sections is not stated any more than the noteworthy absence of indications for his sections

If Dr Potter had written a book whose purpose was to advocate a more frequent resort to version in contrast to high forceps and cesarean sections done for minor obstetric complications there could be no criticism Under such circumstances, the aim of the book would be appropriately "a more extended use of version", but an author, as well as his proponents, has poor logic when it is defended that parturient women should be treated in one of three ways—spontaneous labor for those who terminate their labors before the arrival of the attendant, version in the vast majority, and cesarean section for those in whom version is considered contraindicated As Dr Potter makes a routine practice of operative delivery, he cannot offer indications for his versions or his sections other than the conservation of his time and strength, and incidentally to shorten the labors Even if indications were offered, we would hold them specious for any obstetrician to have a full 99 per cent of operative deliveries

To quote Dr Hayd "Until it is proved, in the hands of other men, that his practice is more dangerous to mother and child the question must be left in statu quo" In Professor Rucker's report on his experience with Potter's version in the *American Journal of Obstetrics and Gynecology* (1 574 [March] 1921), the author is enthusiastic for the method yet his fetal mortality was from 12 1 to 17 55 per cent according to "group"—a gross mortality of 14 5 per cent Professor Rucker is the first Potter enthusiast to report his results—and is still enthusiastic when his fetal mortality is from two to three times the normal experience If this is any criterion, we may only feel that the method has been tried and found wanting in safety or rationality

To answer all of Dr Hayd's comments would take much space especially as his strictures are often not compatible with scientific obstetric thought however, with the limited space available I offer these concrete statements of fact

1 The historical data are correct so far as they go There is a woful absence of facts which associate the steps in the so called Potter's version with the originators of those steps which leaves the implication that Potter originated them de novo There is not one detail of his procedure which could not have been found in the literature

2 It is so self evident that resistance of the soft parts should be overcome that it is common experience of obstetricians that they have ironed out the perineum these many years The necessity is so self evident that to mention it is trite

3 The dictum of one man who has a peculiar facility with one hand cannot refute that common experience dictates that a sane choice of the hand is dependent on the position of the child, or some particular exigency of the case The ready success of version is dependent on so many factors (presentation position indications and anatomic factors) that it is irrational to expect that one fixed, set rule of conduct will fit every condition

4 Peu in 1694 practiced entering the hand between membranes and uterus which Potter implies is his method Any elementary student knows that some interval will elapse between the rupture of the membranes and retraction of the uterus—during which interval, even an hour or two, version is readily possible To argue that Peu's method counts for a better version than when the rupture of the membrane takes place at the internal os, Levret's teaching, is puerility To smear the vaginal contamination, which inevitably must occur from the internal hand to the mucosa of the uterus is not safe obstetrics

5 Pare recommended bringing down both legs Common sense shows that a full breech will secure more dilatation than will one leg brought down, and much more than when both are brought down, essentially, their relationship is 1 ¾ ½ in dilating surface We concede that when rapid extraction is demanded better traction may be secured by pulling on both legs than on one

6 Version is completed with the turning thereafter, if no indication exists the delivery may be left to Nature, or at most manual aid may be employed On the other hand when delivery is imperatively demanded, rapid extraction should be employed As Dr Potter operates on normal women, 'manual aid is his method There is nothing new to this

7 Every operator has found occasion for delivering the anterior arm first Common experience indicates that the posterior arm in the majority of instances may more easily and quickly be brought down than the anterior This is so true that practically every authority recommends it, if the anterior arm may not easily be reached, the shoulders should be rotated so that the anterior arm becomes posterior, delivering it as such Dr Potter, therefore has not originated a detail by bringing down the anterior arm as such, he merely attempts to contravene common experience by being different

8 Figure 15 depicts a distinctly abnormal breech mechanism which is observed occasionally especially in sacral posterior positions, this conforms to the general principles of certain occiput posterior cases forecoming head This is due to some disturbance of pelvic configuration (of the bones or pelvic

floor), and more commonly to factors which determine the rapid descent of the posterior hip, with its anterior rotation again comparable to anterior rotation of the occiput posterior Later, such rotation determines that the back shall be posterior before the shoulders enter the brim In operative cases, if the attendant is not fully conversant with abnormal mechanisms, the pulling on the posterior leg will produce this maneuver *This accident may inevitably occur, but almost* invariably it is a distinct *error of art* As most authorities attempt to depict things as they should be, this illustration is largely new however, in Ramsbotham's book, page 250, Figure 119, fifth American edition, 1849, this position is portrayed in sagittal view, the caption is different There would be no issue on this score if Dr Potter had noted that the illustration showed an abnormal rotation

9 It is refreshing to secure the admission, which we trust Dr Hayd gives authoritatively, that the historical data were supplied by an "abstract company" Is this the explanation of the absence of those grammatical errors in the history that are present in the clinic part of the book? In any event, the explanation does not make the compilation better, and does not excuse the author from advancing it as his own

10 Dr Potter's statement that he only once broke a bone of a living baby is based on such empiric absence of observation that it is misleading If Dr Hayd will read Dr Potter's closing remarks in the *American Journal of Obstetrics and Gynecology* (**1** 642 [March] 1921), he will see the significance of my declaration He there states, "Nor have I X-rayed or made inquiries to know whether there were fractures because I do not think it necessary I know there were none" Injuries and fractures have had a definite incidence in both primary breech extraction and that of secondary breech (after version) in the hands of every obstetric expert who has lived We must therefore discredit the statement of Dr Potter, which may come from lack of routine observation Dr Potter would possibly have a definite incidence of fractures to report if a thorough routine examination were made of all his new-born babies

In conclusion, we may but reiterate what was stated in the review "The teaching, as given in this book, is dangerous and reprehensible, a rational, sane, obstetric thought is imperatively needed if conservation of mother and child are to be realized" An obstetric operative furor does irreparable harm by destroying lives needlessly

[NOTE—While it is not customary to publish responses to book reviews, and the reviewer's reply, space is given in this instance because of the importance of checking this radical trend in obstetrics]

MODIFICATION OF ANTIRABIC VACCINE

To the Editor —Please inform me as to the opinion of the best authorities with regard to the therapeutic efficiency (or prophylactic) of the Cummings Rabies Vaccine compared with that of the regular Pasteur antirabic vaccine which is given in doses of increasing potency

B S PENN M D Humboldt, Tenn

ANSWER—In the series of special articles on biologic therapy published under the auspices of the Council on Pharmacy and Chemistry, A M Stimson (THE JOURNAL, Jan 22, 1921, p 241) wrote

The further treatment of the fixed virus in order to prepare the vaccine may proceed according to several recognized methods, the intent of which is either to accomplish graduation of the dosage, or to secure a further attenuation of virulence, to preserve against rapid deterioration, or merely to provide the material in a form convenient for use Of these methods the most commonly employed are emulsification of the virus and graded dilution in salt solution, reduction of virulence by slow desiccation for definite periods, followed by preservation in glycerin, removal of diffusible substances by dialysis [the Cummings method], rapid desiccation in a frozen condition, and treatment by various chemicals, notably by phenol The advocates of each of these methods can adduce arguments as to the convenience, economy or suitability for some special purpose of the method which they employ, but it is believed that there is no acceptable evidence to show that any one method is preeminently more efficacious in conferring immunity to rabies than others Some methods have, however, been subjected to more extensive practical application than others

Whatever the method employed, the final substance to be used for injection consists of a liquid suspension of more or less modified fixed virus, and this is administered in a series of subcutaneous injections, given for a period of time which may vary according to the method used, up to a maximum of three weeks It has been found possible, and is theoretically advantageous, to modify the schema of injections employed originally by Pasteur in using the virus attenuated by slow desiccation For example, the plan of injections now employed in the Hygienic Laboratory, U S Public Health Service, eliminates the use of long dried and presumably inert material, while retaining roughly Pasteur's idea of administering a succession of courses of injections of increasing virulence This schema is admittedly arbitrary, and is supported more by the evidence of long usage than by strictly scientific considerations"

ENURESIS

To the Editor —Kindly send me any information you have as to the treatment of bed wetting in children and young adults I would appreciate greatly some references for this condition or remedies for it.

Church Missionary Society—At a recent exhibition of the hospital facilities in lands far from civilization held in London England it was announced that the society now has thirty seven mission hospitals five of which have medical schools attached to them There are leper establishments in connection with four of these hospitals eight are equipped with modern roentgen-ray apparatus Physicians are badly needed to continue the work The hospital at Mengo Uganda British East Africa, contains 212 beds with separate blocks for Europeans There is a large dispensary pathologic laboratory, operating room and roentgen-ray room A medical school for twenty-four students adjoins the building A new maternity training school was recently opened and twenty young Baganda women are trained in midwifery yearly and receive a government diploma after examination as certified midwives The Pakhoi Medical Mission Compound is situated 500 miles from Hong Kong China and has 210 beds, including a leper asylum containing 160 lepers who are segregated and treated with chaulmoogra oil One trained nurse (the only white trained nurse) is in charge of this institution, there being no physician there at present Models of the Peshawar Medical Mission the Cairo Mission Hospital and the Church Missionary Society's hospital at Kampele, Uganda, among others, were on view at the exposition

Book Notices

DIE WASSERMANNSCHE REAKTION MIT BESONDERER BERUCKSICHTIGUNG IHRER KLINISCHEN VERWERTBARKEIT Von Dr Harald Boas Privatdozent der Universität Mit einem Vorwort von Geh Med Rat Prof A Wassermann Third edition Paper Price 36 marks Pp 176 Berlin S Karger 1922

This follows the lines of former editions While there have not been many changes or additions, yet the extended personal experience of Boas with the Wassermann test has enabled him to draw valuable conclusions concerning the test After a rather comprehensive historical review, Boas discusses the technic and details of the test, and describes many of the numerous modifications He believes the simple alcoholic extract of human or beef heart the most reliable antigen although he inclines to the belief that the cholesterolized antigen may be of value if properly controlled to rule out false positive findings For the sake of completeness he discusses many of the tests which have been advanced as substitutes for the Wassermann test and believes that the Sachs Georgi and Meinicke tests are the best of these The special merit of this little book is the discussion, based on the personal experience of the author of the presence or absence of positive results in the various types of syphilis From the standpoint of interpretation, Boas believes that a positive test should be regarded simply as a sign or symptom of syphilis and that treatment should be guided by the presence or absence of positive tests However, he warns against placing any reliance on a negative test, except when this appears after a vigorous course of treatment In other words a negative test cannot be understood as excluding syphilis In the incubation period or in the initial stage of syphilis a positive Wassermann test does not usually appear until shortly before the appearance of the secondary symptoms In the secondary as well as in the tertiary stages, this test is almost constantly positive in the untreated cases, but may be negative in those cases in which early treatment has been given In latent syphilis the results are variable, Boas inclining to the view that only the positive reactions have any diagnostic value The same situation is found in tabes and in general paralysis although the reaction tends to be positive in a greater percentage of cases than in the latent types of syphilis As to the influence of treatment on the Wassermann test Boas states that most cases gradually assume a negative condition under protracted treatment, but that treatment may in some cases render a negative case positive or strengthen the positivity of the reaction Further, some cases assume a 'Wassermann-fast' state under certain lines of treatment so that such treatment must be replaced by other measures

SURGICAL AND MECHANICAL TREATMENT OF PERIPHERAL NERVES By Byron Stookey A M M D Assistant Surgeon New York Neurological Institute With a Chapter on Nerve Degeneration and Regeneration by G Carl Huber M D Professor of Anatomy and Director of Anatomical Laboratories University of Michigan Cloth Price $10 net Pp 273 with 275 illustrations Philadelphia W B Saunders Company 1922

This is the first real effort that has been made to place the surgery of the peripheral nerves on the same plane with that of the brain and spinal cord It is a thoroughly complete work being based primarily on the fundamentals of anatomy, embryology and physiology On every point the evidence has been formed from the best and most recent experimental work and the conclusions have been drawn only after a careful analysis of the literature The anatomy of peripheral nerves is dealt with in minute detail particular stress being laid on their embryologic development This is followed by a chapter on nerve degeneration and regeneration by G Carl Huber in which the progress of the experimental work is reviewed completely and clearly and so fairly that the reader can scarcely fail to secure a clear understanding of this field The methods of nerve repair are ushered in by criticism of the old treatments and methods, after which the author elaborates in detail on the technic of nerve suture, nerve crossing and nerve transplantation The methods of bridging a nerve gap, perhaps the most important subject

in nerve surgery from the practical point of view, are then reviewed and carefully analyzed One is impressed with the vast amount of painstaking work that has been done on tubulization by Huber, whose researches since 1895 have so completely altered surgical methods along that line The clinical aspect of the subject is then presented in all its phases, with the utmost care as to minute details As stated in the author's preface, the various syndromes, motor electrical and sensory, so elaborately treated by Tinel and Anasthasio-Benisty, are not particularly emphasized, the great stress being laid on surgical and mechanical procedures suitable to the treatment of peripheral nerve injuries Following an introductory chapter on indications for operation and the time to operate, the various nerves are taken up separately, and a most thorough analysis made of the various means of repairing injuries to them One is constantly impressed with the close adherence to the experimental side and its bearing on the conclusions drawn The facial nerve, the brachial plexus, the musculospiral, musculocutaneous, median, ulnar, lumbosacral plexus and sciatic nerves are dealt with in order, and in connection with each the normal anatomy, development, anomalies, types of injuries and detailed phases of the operative and mechanical treatment are beautifully presented The remainder of the work is devoted to a brief discussion of the nerves less frequently injured, such as the recurrent laryngeal, spinal accessory, long thoracic, subscapular, anterior crural, obturator and gluteal, followed by a treatise on nerve tumors causalgia and amputation neuromas The author deserves unlimited credit for this careful reorganization of the subject of peripheral nerve surgery If any criticism could be fairly made, it would be that there is a lack of clinical end-results to substantiate the principles on which the work is based

LEHRBUCH KLINISCHER DIAGNOSTIK UND UNTERSUCHUNGSMETHODIK FUR STUDIERENDE MEDIZINALPRAKTIKANTEN UND AERZTE Von Prof Dr Theodor Brugsch Oberarzt der II med Univ Klinik in Berlin und Prof Dr Alfred Schittenhelm Direktor der med Klinik Kiel Fifth edition Paper Price 390 marks Pp 968 with 432 illustrations Berlin Urban & Schwarzenberg 1921

This edition comprises almost 1,000 pages of closely printed and compact material covering every method of clinical and laboratory examination One is reminded in perusing this volume of the monumental work of Sahli The first part is devoted to general topics, such as anamnesis and physical examination All the well known and latest mechanical means for diagnosis, as electrocardiography, phonocardiography and roentgenology, are discussed The remainder is devoted to special methods used in the diagnosis of diseases of the various systems The subject of immunology and infection is given considerable space The attempt of the authors to cover as much ground as they do leads to an imbalance It is impossible to enter into differential diagnosis, or to consider in more than the briefest manner the outstanding features of all diseases This defect in the present edition might have been made less apparent by the elimination of a large number of tests which have outlived their usefulness, and the substitution of clinical data for them

A LABORATORY MANUAL FOR COMPARATIVE VERTEBRATE ANATOMY By Libbie H Hyman Department of Zoology University of Chicago Cloth Price $2 50 net Pp 380 with 69 illustrations Chicago University of Chicago Press 1922

This book meets a great need, for comparative anatomy teaching has not been well supplied with laboratory guides It is a pity that the course outlined, or one equally good, is not part of the curriculum of all students preparing for medicine The pedagogic policy followed is sound The problems and needs of the student have been considered with exceptional care and breadth of view Experience with different methods has proved that laboratory guides cannot be too definite The success of a course is largely proportional to the thoroughness of the organization of the instruction The experienced and open minded instructor will appreciate the effort made in this book to facilitate the acquirement of anatomic knowledge every student should have before beginning a medical course The methods employed in this book do not appear to be inconsistent with the spirit of research The student should be stimulated in scholarly ambition by the success which such a book should help him to attain It is possible that, in brief courses, the average student may find too much detail It may be necessary for the instructor in a short course to make limited selections The so called comparative plan, involving an arrangement by systems of organs rather than by types, is followed The importance of a good knowledge of the skeleton is recognized, and there is a commendable phylogenetic point of view There is much supplementary material, including a good glossary and a complete index The reader's convenience is recognized usually, but not always, in the use of complete terms instead of letters in labeling illustrations

THE CHILD AND THE HOME Essays on the Rational Bringing Up of Children By Benzion Liber M D Dr P H Cloth Price $2 50 Pp 253, with 2 illustrations New York Rational Living 1922

The fundamental text of Dr Liber's book is the plea for absolute freedom of will to the child He particularly attacks the cult of obedience, stating that the child is not the property of the parents and owes them nothing, except friendship and affection if they deserve it Presumably the judgment as to whether or not they deserve it rests entirely with the child The writing is marred by frequent uses of involved Germanic constructions The opinions are original, but too radical to be safe There are two prefaces, one at the front of the book by Upton Sinclair, and one at the back of the book by teachers in the Modern School of Shelton, N J There is also a supplementary advertisement of Dr Liber's independent magazine called *Rational Life* which is devoted to such subjects as "Birth Control," "Drugless Treatment of Diseases" and Vegetarianism" Most rational persons would differ with Dr Liber's conception of the rational up bringing of children

Miscellany

SHEPPARD-TOWNER MATERNITY ACT REJECTED BY MAINE

The governor of Maine has rejected, on behalf of the state of Maine, the Sheppard-Towner Maternity Act His rejection holds good at least until the next legislature convenes In a proclamation, issued July 17, he said, in part

I believe the time has come for the states of the Union to hold to a principle and to carefully scrutinize all offers of federal aid' before accepting them Having no doubt as to what my duty is in this matter, I decline to accept the Sheppard-Towner bill, and this state for the time being will stand with New York, Massachusetts and Rhode Island, the three states that have rejected it The state of Maine will not sell its birthright, and principle, not expediency, has been the determining factor with me in the solution of this problem

'The people of Maine are willing and able to care for their own mothers and children, and I have faith to believe that Maine men and women will do this rather than accept so-called gratuities from a federal bureau

The Sheppard-Towner bill is to be attacked in the courts by the commonwealth of Massachusetts, and eminent lawyers are of the opinion that the federal government has no power over the states in maternity and child welfare matters There also is grave doubt as to whether or not the governor of a state has the power to accept the bill in question, even though Congress attempts to confer that power upon him The governor of a state does not derive his authority from the federal government, and a federal bill that seeks to confer new power upon him is of questionable standing

The existing provisions of the Sheppard-Towner bill are reasonably moderate, but it properly may be assumed that attempts will be made to broaden its scope so as to further restrict the state's control over its own affairs It is apparent that the present bill is but an entering wedge for more radical legislation, and Maine s delegation in Congress, our

senators and representatives should be urged to resist all further encroachments upon the states by the federal government Maine will loyally support the Union in all matters that come under the provisions of the federal constitution, but the time has arrived when the people of this state will jealously guard the rights inherent in them as a sovereign people and will accept the responsibilities the possession of such rights imposes

"In years gone by the state of Maine has not hesitated to stand for great principles, and it is well for the forty-four states that have accepted the Sheppard-Towner bill to know that Maine neither asks for, nor for the time being accepts, federal aid for its mothers and children"

DRINKING WATER ON TRAINS

The Interstate Quarantine Regulations require common carriers to provide water for drinking and culinary purposes that is of satisfactory sanitary quality, further, that cooled water shall be handled in such a manner as to prevent contact with the ice The drinking water supplied in trains in the coach yards of Chicago and of other terminal cities of the Middle West was recently studied by A E Gorman, assistant sanitary engineer, U S Public Health Service He found that the railroad companies in nearly every instance were making an honest effort to meet the requirements of the quarantine regulations However owing largely to a lack of understanding of sanitary practices, some yard and coach foremen were permitting serious insanitary practices The most dangerous filth common to coach yards is fecal matter apparently dropped from the toilets of cars These droppings are altogether too common and when eliminated, a big factor in jeopardizing the drinking water supplied cars will be removed Yard trainmen and other employees Gorman recommends, should be forbidden to use the car toilets Water tanks are filled usually by means of the ordinary garden hose, which in some yards is dragged along the ground from car to car with no protection to the ends The hose is often leaky, or the free end may be frayed and while it is being dragged, filth may enter the hose or contaminate the ends In sterilizing water coolers Gorman found that the cooler was often placed on the ground over a short piece of air hose Steam lines were seen in two instances in Chicago actually lying in fecal deposits The steam table used by some yards is commendable Handling ice for water coolers is difficult, and employees sometimes put small pieces of ice in the coolers that have not been washed after falling to the ground Separate ice and water compartments will when generally used remove much of the danger from contaminated ice But even when separate compartments were in use, ice was found in many cases in both compartments Separate openings should be provided for filling ice and water compartments in coolers Gorman believes that health officials and railroad officials should confer on the matter of standardizing coach yard design, and the manner of handling ice and water

CONFERENCE ON VENEREAL DISEASES

The Northern European Red Cross Conference which met in Copenhagen in May, 1921, and which comprised delegations from England, Germany, Holland, Denmark, Norway, Sweden and Finland, adopted, among others, the following resolutions

The questions of compulsory notifications and of compulsory treatment being dependent on the experience resources and psychology of the people concerned in each country must be decided by individual nations

The regulation and official toleration of professional prostitution have been found to be medically useless as a check on the spread of venereal diseases and may even prove positively harmful tending as they do to give official sanction to a vicious traffic

Enlightenment of the general public on lines which are best calculated to minimize exposure to infection and which emphasize the necessity of thorough treatment is an essential part of any scheme for the combating of venereal diseases Instruction should particularly be addressed to parents and teachers in such a form as will enable them to give clear information on the reproduction of life and impress on adolescents the importance of individual responsibility to future generations. In the training of teachers special courses on these subjects should be provided

Medicolegal

Osteopath's License Held Properly Revoked

(Harlan v Alderson et al (Calif) 205 Pac R 1014)

The District Court of Appeal of California, First District, Division 1, in reversing a judgment that annulled an order of the board of medical examiners which revoked respondent Harlan's license to practice osteopathy in that state, says that in 1916 he was granted a reciprocity certificate to practice osteopathy, and early in 1920 proceedings were initiated before the board by a verified complaint against the respondent, charging him with a violation of the ninth subdivision of Section 14 of Chapter 354 of the Statutes of 1913, as amended in 1915, 1917 and 1919 The uncontradicted evidence introduced at the hearing showed that he wrote prescriptions and performed both minor and major surgery and engaged in the unlicensed practice of medicine and surgery The question presented to this court was whether or not the case fell within the provisions of Subdivision 9 of Section 14 of the Act of 1913 which provides what shall constitute misconduct which shall warrant the board of medical examiners in revoking a license granted under the provisions of this act and which reads

Ninth The use by the holder of a drugless practitioner certificate of drugs or what are known as medicinal preparations in or upon any human being or the severing or penetrating by the holder of said drugless practitioner certificate of the tissues of any human being in the treatment of any disease injury deformity or other physical or mental condition of such human being excepting the severing of the umbilical cord

The court thinks it did so fall The well-settled definitions of osteopathy both in the decisions and in the dictionaries uniformly hold that the system of osteopathy "uses no drugs It administers no drugs it uses no knife As a remedy a form of manipulation is used" Wherefore, under the present classification, there can be no doubt that one holding an osteopath's license issued prior to the act of 1913, or subsequent thereto on the basis of a previously secured license from another state would, if originally licensed in California since the Act of 1913, be licensed as a "drugless practitioner And by virtue of Section 21, proceedings for the revocation of a reciprocity certificate must be had under the section under which such certificate would have been issued if originally issued under the provisions of this act.

A hearing was denied by the Supreme Court of California

Opinions of What Might Be Expected from Injuries

(Posch v Payne Director General of Railroads (Minn) 186 N W R 132)

The Supreme Court of Minnesota says that the plaintiff on alighting from a train Oct 25 1919, fell on a sloping platform A physician was called to attend her and mainly from complaint of pain, diagnosed the principal injury as an impacted fracture of the right leg The plaintiff was treated accordingly The evidence on the trial made it reasonably clear that the leg was not broken at all Then in June or early in July 1920 the plaintiff became pregnant, and there was a miscarriage in September which she claimed was a natural and proximate result of the injury She also claimed that as a result of her injury, which affected her nerves, she lost in a measure the sense of hearing in her left ear although by the fall she suffered no injury to the ear nor to her head so far as the evidence showed She was given a verdict for $10 000 damages In reversing an order denying a new trial the supreme court holds that it was prejudicial error to refuse requested instructions withdrawing the items of miscarriage and deafness from the consideration of the jury on the question of damages That the accident or fall on the station platform so injured or disarranged the internal organs of the plaintiff as to render miscarriage more likely to result from pregnancy subsequently occurring was not shown by any reliable evidence and the opinion of the medical expert to that effect was altogether too speculative and conjectural

to furnish a basis for legal liability against the original wrongdoer The case would be entirely different had pregnancy existed at the time of the accident And whatever deafness she experienced was but theoretically traced by her medical expert witness to the nervousness brought on as one of the results of the accident

The opinions of medical experts as to conditions naturally to be anticipated and expected to follow from given personal injuries are of great value to courts as aids in the determination of questions of that character, and entitled to serious attention and consideration in the pronouncing of judgment thereon Such opinions, however, are not controlling on the court, and the value and probative force thereof diminishes in proportion as the evidence indicates clearly to the practical lay mind a professional entry for support into the field of theoretical uncertainties and doubts Such the court believes the field drawn from in this case by the expert, who attributed the plaintiff's subsequent ailments in the particulars stated as a probable consequence and result of the accident in alighting from the train at the time in question For the error in submitting to the jury the elements of damage referred to, there must be a new trial

Physician Entitled to Jury Trial on Claim

(In re Stein's Estate (N Y) 193 N Y Supp 298)

The Supreme Court of New York, Appellate Division, Fourth Department, says that in December, 1918, a physician presented a verified claim against the estate of one Stein, deceased, for $81,461 01, for professional services rendered to said Stein under a contract In April, 1919, the executor rejected the claim by written notice served on the claimant More than a year elapsed, and nothing was done by the executor toward settling the estate or adjusting this claim, and in May, 1920, the claimant began a proceeding in the surrogate's court for an accounting There was much delay on the part of the executor in filing his account, and many adjournments were had Finally, a formal written demand for a jury trial of the issues was filed by the claimant The surrogate determined that the claimant was entitled to have the issues tried by a jury as a matter of right, and made an order accordingly, which order is here affirmed The claim was for professional services alleged to have been rendered by the claimant as a physician and based on a contract, and so long as he made claim for a sum of money only, the granting to him of the right to have the controverted issues of fact tried by a jury on the judicial settlement was simply affording a procedure in the surrogate's court similar to the procedure a claimant had always been entitled to adopt in a common law action in the supreme court of New York The demand for a jury trial in this case was seasonably made and was never waived The claimant had a right to bring his action in the supreme court within the time provided by statute, or have a trial in the surrogate's court on the judicial settlement of the estate, but with equal rights to a jury trial in both cases

Statistics of Multiple Sclerosis I S Wechsler New York—p 59

Chronic Epidemic Encephalitis—The case of epidemic encephalitis reported by Schaller and Oliver, representing both clinical and anatomic examinations, is of particular interest because of the persisting inflammatory brain changes after fourteen months, and also because complaints of abdominal pain, muscle spasm and gastric distress thought to be due to local causes ultimately led to an exploratory laparotomy This exploration revealed no pathologic condition to account satisfactorily for the abdominal symptoms, and the final analysis of the case explained these symptoms as being due to brain lesions

Sugar in Blood and Spinal Fluid in Epidemic Encephalitis—Thalhimer and Updegraff found that in epidemic encephalitis the sugar content of the blood and spinal fluid is increased but only after a certain level of blood sugar has been reached At present hyperglycorrhachia can be used chiefly to differentiate epidemic encephalitis from the two conditions with which it is most likely to be confused—tuberculous meningitis and early poliomyelitis

Localization of Spinal Cord Tumors by Dyes—The method described by Selling consists of two steps first, the demonstration of spinal subarachnoid block, by the Ayer method, second, the injection of a dye into the cisterna magna, or into the lumbar subarachnoid space The injection is made immediately prior to operation Assuming that the lumbar route has been used, the dye will diffuse through the subarachnoid space up to the lower pole of the tumor The existence of a subarachnoid block will prevent its going beyond this point If the laminectomy opening is below the tumor, on opening the dura a deep blue stained fluid will be encountered The laminectomy must then be extended upward If, on the other hand the laminectomy has been above the level of the tumor on opening the dura a colorless fluid will be encountered The opening must then be continued downward

Cerebrospinal Fluid in Multiple Sclerosis—The spinal fluid findings in thirty-eight cases of multiple sclerosis, together with certain blood examinations in a number of these, are given by Ayer and Foster They state that there is no single fluid test of paramount value in the diagnosis of multiple sclerosis However, correlation of all tests ordinarily performed on the spinal fluid indicates that it is seldom entirely normal, and that in 50 per cent of the cases of this series findings unusual in other diseases were obtained This group of findings, which the authors consider important, is as follows fluid of normal appearance, obtained under normal or low pressure as registered by the manometer, showing a slight increase in cells (lymphocytes and arachnoid mononuclears), total protein normal or only slightly increased, globulin, a slight trace or absent, and a paretic colloidal gold curve with a negative Wassermann reaction Correlation with the clinical picture suggests that this type

of fluid indicates a progressive stage of multiple sclerosis Conversely, normal or nearly normal fluids were found primarily in patients in whom no clinical progress had recently been apparent Results of certain chemical studies designed to show disorders of metabolism in this disease, performed on blood and spinal fluid, were normal

Exogenous Causes of Multiple Sclerosis —The possible exogenous causes considered by Barker are (1) the influence of earlier infections, (2) the influence of intoxications, (3) thermal and electrical influences, and (4) trauma If the exogenous factors mentioned play any role at all in the etiology of the disease, Barker says, they must act either as predisposing influences for the true cause or as aggravators of a disease already started by the true cause

Geographic Distribution of Multiple Sclerosis —The results of the tabulation of multiple sclerosis as one of the defects found in drafted men are plotted by Davenport and the results discussed It shows that the maximum rate for this disease was found in Michigan and Minnesota in which there were eighteen persons with this disease per 100 000 Excepting Delaware and the District of Columbia (whose *rates depend on one and two cases, respectively*), the next highest ratio is that for Wisconsin, fourteen per 100,000 That these states with a high ratio for multiple sclerosis are adjacent states, bordering on the Great Lakes, is regarded by Davenport as of great interest In discussing the etiology of this disease Davenport suggests that the factor of heredity cannot be left out of consideration

Statistics of Multiple Sclerosis —Wechsler's study is based on the records of 1,970 cases of multiple sclerosis and includes the infantile, congenital, familial and hereditary forms and the mental and psychic symptoms

Heart Disease in Industry W I Clark Jr Worcester Mass —p 21
*Infantile Heart in Adult Life L F Bishop New York —p 23

Social History in Heart Disease —Four cases are cited by Reid illustrating the importance of the social history in patients of an outpatient heart clinic The social history often discloses why certain patients fail to make an expected improvement At times the skilful utilization of such data greatly increases the therapeutic success achieved The social history may contain information of value in the diagnosis of that type of patient held to have an 'irritable heart" Attention to the social history opens up a big broad, humanitarian side of the practice of medicine Further justification of emphasis of the social history is found in that it keeps alive the fact that patients are not mere medical cases but living human beings

Infantile Heart in Adult Life —The infantile heart, Bishop says, is met with as a recognizable condition from the tenth year onward The man with an infantile heart can go as far as he will, without injury to the heart, because his wind gives out and he must stop The syndrome of an infantile heart is a right predominance, sinus arrhythmia, a history of palpitation, and a soft blowing murmur above and to the left of the middle of the sternum The fluoroscope usually shows besides a centrally located heart shadow, a fairly definite predominance in the region of the conus An interesting problem has been the recognition of this condition in later life On several occasions, Bishop says, he could surmise that this condition had existed in the early life of people who later developed extremely high blood pressures (230 and 240, and the like), which could not be accounted for in any way, and which were carried with an unusual degree of tolerance They differ from the ordinary high blood pressure cases in that their hearts are not markedly the subject of a left predominance There may even be a right predominance at an advanced age A certain number of infantile hearts seem later to conform to the normal type In other words, in popular language, the condition is outgrown

Common Parasitic Dermatoses in Southern California —Ectogenous parasitic dermatoses, according to Scholtz, make up about 30 per cent of the total number of skin diseases in Southern California The most widespread in the order of frequency are streptodermias, tinea, scabies and staphylodermias Scholtz urges that a more thorough isolation of skin lesions caused by streptococci, staphylococci, tinea and scabies should be enforced in schools and in homes A sanitary inspection of domestic animals, particularly dogs and cats, in all homes from which cases of tinea are reported, *is highly desirable as these animals seem to be the main* agencies in spreading tinea Cases of tinea and scabies should be reportable

Basic Diet in Nephritis —Sansum asserts that by the employment of what he terms a 'basic diet," the urinary acidity may easily be reduced to a p_H of 7 or better On such diets patients with chronic interstitial nephritis appear to improve as evidenced by a decrease in blood pressure, albumin and casts in the urine and other symptoms of nephritis and arterial hypertension

Diabetes Insipidus Symptoms Coincident with Breast Cancer Metastasis in Skull —Cross patient was a woman, aged 58 who complained chiefly of excessive thirst of very frequent urination of weakness, of peculiar morning vomiting and of marked disability in the lower part of the back At 48 the left breast was removed by a competent surgeon because of a tumor supposed to be a carcinoma The present illness had its beginning seven months before consultation Summing up the situation the principal features were as follows (1) loss of weight and strength, (2) gastric symptoms including nausea morning vomiting and anorexia, (3) polyuria and polydipsia, (4) disability of the spine Of these, *the fourth was easily explicable, apparently, on the*

basis of roentgen-ray findings of infectious arthritis of the spine No local cause had been found for the gastric symptoms Urinary studies, blood findings and blood pressure were all rather against the polyuria being a manifestation of chronic nephritis, and there was nothing to suggest that it was of hysterical origin Roentgen-ray studies of the skull showed scattered through the cranial bones, particularly in the parietal and frontal regions, numerous rarefied areas of bone destruction, showing no evidence of new bone formation, the process in the bones was apparently invasive in character, in every way resembling the changes in malignancy The patient died on the third day of coma Cross regards the case as one of multiple, malignant metastases in the bones of the skull, at the base of the brain, and, possibly, also in the lumbar spine It is probable that the involvement of the base of the brain affected the mechanism regulating water metabolism, so that symptoms of mild diabetes insipidus developed The origin of the metastases is uncertain, but it is quite possible that they were secondary to the breast cancer removed ten years before

Endameba Histolytica in Testes in Dysentery—Warthin's case presents the unique occurrence of the metastasis of *Endameba histolytica* to epididymides and testes with definite though slight, local lesions in these organs, in a patient affected for many years with amebic dysentery, at the time of death nearly completely healed, with disappearance of amebas from the stools It is the first recorded instance of such a localization of *Endameba histolytica,* and presents additional evidence of the mildly pathogenic character of this parasite, in the slight tissue destruction caused by it and its phagocytosis of red blood cells and spermatozoa A point of some interest is the localization of the small lesions in the rete testes and tubuli efferentes with long streaming clots extending upward into the epididymis, the amebas being held within these clots In the dilated semen filled portions of the epididymis the organisms were found in greater numbers and free in the semen Their commensal character is shown by the phagocytosis of red blood cells in the clots, and by that of spermatozoa in the semen particularly, that is, they show the same tendency in the semen to feed on substances contained in it as they do on the substances in the intestinal contents

Excretion of Spirochete by Kidneys—In three cases of congenital syphilis studied by Warthin, one of a child dying at birth another dying eight days after birth, and the third at 3½ years of age, the kidneys presented an unusual degree of spirochete localization with definite lesions In two cases of acquired syphilis, those of a young man with a roseolar eruption and a young woman with maculopapular eruption, both dying from arsphenamin poisoning, a similar localization of spirochetes in the kidneys with positive evidences of excretion through the renal epithelium into the tubules was observed Identical conditions and changes were present in all five of these cases No arsphenamin treatment had been administered to the patient with the congenital case dying soon after birth or to the child of 3½ years, but it had been given to the child dying at 8 days of age, and the death was supposed to have been due to the treatment The child of 3½ years of age had albuminuria and symptoms suggesting poliomyelitis, the young woman of 23 years had casts and albuminuria, the urine of the young man had not been examined He was suppo edly in good condition, except for the chancre and the roseolar eruption

Nocardiosis of Lung—The patient whose case is cited by Callender and Coupal, two years before death inhaled into his right bronchus a chicken vertebra He minimized the importance of the size of the bone and repeated roentgen-ray examinations failed to reveal it A few months after the accident the patient had a severe attack of "influenza" with pneumonia which was especially localized on the right side A year later there was a train of symptoms of the same character During the interim the patient was in comparatively good health Following this second attack until his death (a period of seven months) the patient gradually failed He had a cough, high temperature, pain in the right side and shortness of breath Bacteriologic examinations were negative but physical examination and roentgenograms indicated a tuberculous process Two weeks before death there was evidence of embolic processes as indicated by the cerebral attack and the abscess on the leg Signs were found of old tuberculosis of the apexes It is impossible to determine accurately the exact onset of the infection with nocardia It seems not unreasonable to suppose that the focus of diminished resistance produced by the bone in the bronchus gave a satisfactory lodging place for this organism which probably came from the mouth and that it slowly developed during the last seven months of the patient's life, then by its formation of abscesses it gained access to the blood stream and produced a nocardial pyemia during the last two weeks The organism belongs to the streptothrix group and is a rather unusual type in that it is apparently an absolute anaerobe

Ameba in Kidneys—An ameba-like organism, the apparent cause of an acute parenchymatous nephritis, was found by Jackson in the kidneys of a child, 15 months old who died suddenly in a convulsion Neither the gross nor histologic examination of the tissues revealed any other apparently sufficient cause of death Three reports are found in the literature of the occurrence of somewhat similar organisms in the kidneys, twice in syphilitic fetuses and once in a stillborn, nonsyphilitic child

Complications of Diabetes Mellitus—The more important complications of diabetes mellitus are discussed by Marsh It is pointed out that some of the complications are important because of their effect on the diabetes, some because of the effect of the diabetes on the complications and some because they are distressing to the patient and may be fatal The importance of prophylaxis of most of these complications by thorough dietetic treatment of even the mildest cases of diabetes is emphasized Attention is called to the fact that success in the treatment of complications may be expected only if the diabetes is kept under control

Portal Cirrhosis in Child with Operation—The case reported by Kay and Ginsberg is one of the undoubted cases of alcoholic cirrhosis and in addition is a presentation of the only case of cirrhosis of the liver in childhood that has been treated by the Talma-Morrison operation (though with a fatal outcome) The boy, aged 11, developed the habit of taking drinks of an alcoholic beverage, which he described as vodka, stating that it was very strong and hard to take at first, but he soon became accustomed to it and learned to take it and enjoy it, receiving a small glassful three times a day He never reached the stage of intoxication His drinking periods extended over three months a year for three years The father noticed that the boy's abdomen began to enlarge and as he aptly put it, "the belly got bigger and the boy littler" The size of the abdomen increased steadily During this period the boy had periodic attacks of vomiting On one occasion hematemesis occurred Emaciation had been continuous and rather marked, accompanied by an increasing cachexia

Convalescent Human Serum in Treatment of Scarlet Fever—Bernbaum reports on an analysis of thirty-nine cases of scarlet fever treated at the Herman Kiefer Hospital with convalescent serum for the year ending July 1, 1921 Thirty-two patients lived and seven died Of the seven who died, two were practically moribund, one died within twenty-one hours and the other eighteen hours after entrance, one after eight days of acute hemorrhagic nephritis, one after eight days of septic complications Three died of toxemia Two of these received only 10 c c of serum and one 20 c c Of the thirty-two surviving cases, twenty were toxic and twelve had septic complications The average dose was from 10 to 35 c c intramuscularly The serum was administered from the third to the eighth day of the disease Children responded as well as adults Eighteen cases were treated so far the fiscal year, beginning July 1, 1921 These were the most severe of all cases of scarlet fever admitted since that date Of these eighteen, five died One died of pneumonia and sepsis after two weeks One died in twenty-four hours from myocardial failure One died of general sepsis following extensive adenitis One was sick one week before entrance, came into hospital almost moribund and died within fourteen hours One died of toxemia, but had received only 30 c c of blood, which is equivalent to about 10 to 12 c c of serum Even some of these cases showed improvement after the administration of serum Of the thirteen recovered cases, four were of the pure toxic type The blood was taken from healthy donors, Wassermann negative in the fourth or fifth week of the disease The serum was injected intramuscularly in all cases The blood was obtained from the median cephalic vein of the donors by the syringe method or into a mouth suction bottle Fresh whole blood, citrated whole blood centrifuged citrated blood, serum from defibrinated blood, citrated blood run through a Berkefield filter and decanted serum after standing were used The effect from the serum obtained in any way was identical

Diphtheria Antitoxin Administered Intravenously—Sachs states that antitoxin should be given intravenously only in severe cases in which there are present excessive membrane and toxemia

Two Cases of Cesarean Section—One of Applegate's patients had a large uterine fibroid, the nature of the dystocia being undetermined in the beginning, the other case was a breech presentation in a primipara with a pelvis below normal in dimensions and a fetal head oversize and greatly out of proportion to the pelvis

Carcinoma of Cervix in Nullipara—Hammond reports nine cases Only one of the patients was under 30 He urges that a careful history be taken of every case of pelvic disease, more especially when bleeding is a symptom, and, the physician must not be influenced by the age or social status of the woman, when making a pelvic examination, the patient must be approached with the firm determination of making a positive diagnosis

Ovarian Therapy in Involutional Melancholia—Although no definite connection between any of the symptoms of so-called involutional depression and ovarian function has been determined by Strecker and Keyes, it seems probable that in a limited number of patients the injection of ovarian extracts exerts a favorable influence on the general physical status and perhaps more particularly it lowers and stabilizes the blood pressure while possibly in a small group a corresponding helpful influence is exerted on the course of the psychosis The most important and definite physical changes resulting from experiments made on all fourteen patients were a drop in diastolic blood pressure and in eleven patients a drop in systolic pressure, ten patients gained in weight, six improved markedly in appetite, six showed improvement in quantity and quality of sleep, one reestablished menstruation after an absence of seventeen months, in one there developed a decided improvement in troublesome menstrual manifesta-

Dr. Robert Kelly Cravens

tions, and eight showed rise in the percentage of eosinophils No one patient is any worse than before medication started and there is a noticeable improvement in the general physical condition of the group as a whole

Pregnancy Following Menopause—Brandt found only five other authentic cases of pregnancy occurring after menopause in the literature His patient was 46 years of age Her last menstrual period occurred in June, 1916 In May, 1919, she was delivered of a male child weighing 9 pounds Incidentally, this child showed all the signs of achondroplasia Ten months after the birth of the child, the patient after weaning the baby, began to menstruate and had three normal periods The menses have not returned since then

Incidence of Diabetes Mellitus Among Filipinos—Concepcion shows that the mortality of diabetes mellitus in the city of Manila has gradually been increasing from year to year, especially within the last few years This increase is only apparent, due to a greater accuracy of vital statistics There is no reason to believe that increased consumption of sugar is one of the main factors responsible for the greater frequency of diabetes in the last few years At least this supposition will not hold true in the city of Manila as there is no corresponding increase in mortality from diabetes due to the increased consumption of sugar per capita The incidence of diabetes in the Philippines is very much less than in other countries, including Japan The disease is most frequent between the ages of 40 and 50 among Filipinos This is also true among Japanese and Chinese Among Europeans it occurs most commonly between 50 and 70 The slight difference may be explained by the early maturity of Orientals as compared with Europeans Diabetes mellitus as it occurs among Filipinos is of a milder type than among Europeans and Americans The mortality of those suffering from it is very low and only a small percentage die of diabetic coma The low incidence of diabetes mellitus among Filipinos and other Orientals may be explained as due either to greater power of assimilation for sugar among these people compared with Europeans and Americans, or to the fact that they are less exposed to continuous nervous strain on account of their peculiar modes of living It may also be due to some peculiar racial tendency or characteristic This point is of interest, as in the Philippines the diet is largely carbohydrate, for that reason diabetes should be more frequent here than in other countries which, however, was found not to be the case

Spontaneous Jejunal Ulcer—Twelve cases of spontaneous occurrence of peptic ulcer in the jejunum are cited by Richardson, ten being taken from the literature Of the twelve cases nine occurred between the ages of 45 and ten were in men In five necropsies in which the condition of the whole bowel is mentioned, the jejunal ulcer was the only one present in the intestinal tract, excluding for these cases a general ulcerative process In the remaining cases, only one intestinal ulcer was actually demonstrated although more might exist In six cases, confirmed five times by necropsy, and once, in Richardson's case, by operative evidence and roentgen ray, the stomach and duodenum were apparently negative Two cases showed a lesion of the duodenum or stomach In four cases the condition of these organs is uncertain The most frequent situation for the ulcer was within a few inches of the end of the duodenum, occurring there five times The other ulcers lay between this point and the middle of the jejunum or possibly lower The ulcer in seven cases showed evidence of chronicity, and was associated three times with a definite stricture of the bowel In two cases the ulcer seemed acute, in the remaining case the point is not clear Perforation occurred ten times in the twelve cases No definite etiology may be assigned to these cases Richardson suggests the possibility that disturbance of pyloric control may lead to gastric contents reaching the jejunum without neutralization and so to the formation of true peptic ulcer For ulcers situated lower in the intestinal tract, this cause seems improbable Since syphilis produces a form of intestinal ulceration which affects the jejunum more readily than the ileum, and also has a tendency to cicatricial contraction and perforation, it must be considered as a possible cause of ulceration in some of these cases although definite confirmatory evidence is lacking Two points are of particular importance in future cases a careful microscopic study of the lesions, including if possible the mesenteric lymph nodes, and the determination of the presence or absence of syphilis

Surgical Treatment of Stomach and Duodenum Ulcers—Nineteen cases are reported by Hromada and Newman Five patients died All were admitted to the hospital showing clinically wide-spread acute peritonitis In all of the cases, the cause of illness was diagnosed before operation In all cases resection of the stomach was done, and more than two thirds of the stomach was removed in two cases following

the Billroth method and in the rest the Kroenlein-Mikulicz method The duration of time between perforation and operation was from one and one-fourth to thirty-six hours All patients were given as little anesthetic as possible, morphin and ether being used All other details—history, condition of patient, findings at operation, condition after operation, and reexamination—are mentioned in the report of cases The ages ranged from 24 to 56 years, and the patients came from all walks of life—which has a bearing on the general state of the patient—nourishment and strength The cases in which a good prognosis could be made were treated by nonradical resection within the first twelve hours after perforation Local anesthesia has no advantage One patient died of an unusual complication—thrombosis of the subclavian artery with subsequent gangrene of the upper extremity—after having fully recovered from the peritonitis The intestinal function was fully restored on the second day after operation, the patient did not vomit, he could even take fluid diet and he had no pain whatever in the abdomen

Marginal Ulcer Follows Polya Operation—Hoguet and Cole assert that this is the only case of a marginal ulcer following a Polya operation recorded in literature The clinical course of the formation of the second ulcer could be followed closely

Recurrent Dislocation of Patella—MacAusland and Sargent make eight operations as follows An incision through the center of the patella tendon from the patella to the tubercle, cutting it off at this point on the outer half This half is then quilted with chromic catgut No 3, turned in under the inner remaining half and sutured in a bony groove as far as possible to the inner side on the inner face of the tibia The periosteum is then pulled over this insertion and the thin capsule pulled over these tendons

Germicidal Value of Colloidal Silver Salts—Colloidal silver salts, notably the chlorid, according to Ballenger and Elder, give off definite germicidal emanations These emanations prevent the growth of micro-organisms on Petrie agar plates in the immediate area surrounding the sealed glass tubes containing the colloidal silver chlorid A 1 per cent preparation has a germicidal value about equal to pure phenol yet when sealed in the anterior urethra for five hours is without pain, even with much stronger preparations No irritation is produced when applied to mucous membranes such as bladder nose, throat, sinuses, etc Good results followed its application to abscess cavities, fistulous tracts, and also when used as a wet dressing for infected wounds, mastoid incisions, etc Diluted 4 000 times, a 5 per cent preparation killed the spirochetes from a foul mouth in four minutes Given intravenously to rabbits artificially infected with the staphylococcus, 1 c c of a 1 per cent preparation cured the rabbits sterilizing their blood within twenty-four hours, while controls, untreated, died within forty-eight to seventy-two hours with multiple abscesses of the liver, kidney, heart, and other organs

Addison's Disease Complicating Pregnancy—To eleven cases recorded in the literature Fitz-Patrick adds one case The Pirquet and tuberculosis complement fixation tests were negative

Treatment of Chronic Bone Abscess—In cases of chronic bone abscess in which clinical signs—daily mild elevation of temperature, slowly increasing pain and tenderness—indicate that the pus is not sterile but that the virulence of the organisms is slight, Brickner suggests that simple evacuation through a small opening is well worth a trial, provided the patient is under close observation It must be remembered that, although the bone opening is relatively small, drainage is provided

Primary Carcinoma of Gallbladder—Among 525 operations performed for various affections of the gallbladder and biliary passages there were twenty cases of primary cancer of the gallbladder, a percentage of 3 8 The association of gallstones with primary carcinoma of the gallbladder is very striking In the twenty cases diagnosed primary carcinoma at operation stones were demonstrated in ten cases, 50 per cent but in many of these cases the gallbladder was so involved in growth that stones could not be demonstrated, even though present Investigations of others seem to show that gallstones are associated with primary cancer of the gallbladder in from 70 to 95 per cent of cases

Hernia of Liver and Intestine—Caudil relates two cases In one the greater part of the small intestine the cecum appendix ascending and transverse colon, had escaped through an opening at the umbilicus, apparently no larger than a twenty five cent piece The umbilical cord had been completely divided to the point of ligation The extrusion occurred while the mother was in the third stage of labor In the second case the baby was well developed and normal at birth with the exception of a large hernial protrusion from the umbilical region The mass was the size of a large orange and very hard and extended from the umbilicus to the

ensiform cartilage, the umbilical cord coming off from the lower portion of the mass The hernia was covered with a thin glistening membrane The anterior abdominal walls were well developed, the hernial mass being very much constricted at point of emergence from the abdominal cavity The hernia contained nothing but the liver which was apparently very much enlarged

Aneurysm of Ductus Arteriosus —A girl, aged 6 years, died from a sudden and profuse hemoptysis There was a history of measles followed by diphtheria five months previously, and six weeks later she suffered from "pleurisy" and had not been well since On admission she was complaining of pain in the left side of the chest with cough and feverishness There was a soft systolic murmur at the apex and over the sternum Examination of the lungs showed some dulness in the left infraclavicular and suprascapular regions with diminution of the breath sounds and some crepitation over the right apex in front As the case progressed, the dulness at the left apex became more pronounced and the apex beat extended further to the left The short systolic murmur disappeared The temperature remained moderately elevated (from 100 to 101 F) throughout The necropsy disclosed a rupture of an aneurysm of the ductus arteriosus into the lung

Cancer of Tongue Excision of Tongue Cancer of Stomach 34 Years Later J S Manson —p 996

Duodenal Tube in Diagnosis and Treatment of Biliary Disease —Apart from its value as a diagnostic measure Meakins asserts that the use of the duodenal tube lends itself to treatment In cases of biliary stasis independent of complete obstruction it is advisable to promote free and periodical emptying of the gallbladder and passages This is of particular importance when the stasis is associated with some chronic inflammatory process If cholelithiasis is present and there is good reason to avoid an operation, if possible, much in the way of amelioration may be expected This hope is especially warranted when it is realized that in practically every case of cholelithiasis, a chronic infection of the biliary passages is present, which infection perpetuates and is perpetuated by biliary stasis in the manner of a vicious circle Several cases in point are cited

Acute Jejunal Diverticulitis —Christie's patient complained of acute pain in the left side of the abdomen, below the umbilicus At the site of the pain there was distinct tenderness on palpation and a suspicion of slight rigidity On deep inspiration a round mass could be felt somewhat larger than a tennis ball, about midway between the umbilicus and the symphysis pubis, just to the left of the middle line The lump was hard and of the consistence of a uterine fibroid, though it was extremely tender Vaginal examination did not offer any assistance in diagnosis, and per rectum no fullness could be felt through the pouch of Douglas The swelling was not particularly mobile, though it was circumscribed Operation was performed fourteen days after the onset of the acute phase of her illness On opening the peritoneum, a quantity of serous peritoneal fluid escaped About the center of the abdomen, to the left of the middle line, was a mass somewhat larger than a tennis ball and entirely covered with a thick layer of omentum When the swelling was denuded of its omentum, there was exposed a large spherical mass, tense and fluctuating about the size of an apple springing from the antimesenteric border of a loop of small intestine A large gangrenous patch was disclosed on the fundus of the swelling, with a perforation in its center through which very foul smelling pus and semisolid contents escaped It was obvious that this was a condition analogous to acute inflammation of a Meckel's diverticulum, which had perforated soon after the commencement of her illness but which had fortunately been successfully dealt with by the omentum The origin of the diverticulum from the jejunum about 9 inches below the duodenojejunal junction was established

Amebicidal Action of Conessine —Conessine, an alkaloid having the formula $C_{24}H_{40}N_2$ which has been isolated from several members of the family of *Apocynaceae*, is shown by Brown to exert a very strong inhibitory action on the growth of free living amebas, in fact, exactly equal to that of emetin Infusions of the seeds of these plants have for many years been used in India with marked success in the treatment of chronic dysentery Although when administered subcutaneously conessine produces an area of necrosis at the site of inoculation, it can be administered by the mouth or intravenously in suitable doses without producing symptoms It is approximately 50 per cent less toxic than emetin A diminution of the inhibitory action on free living amebas of solutions of emetin and conessine which have been in contact with intestinal mucus is shown The serum of patients receiving full and repeated doses of emetin has apparently no amebicidal action, hence it is unlikely that the presence of conessine in blood serum could be detected by its effect on amebae The drug was used in the form of the sulphate. The subcutaneous M L D of conessine for a mouse is approximately 3 mg, and of emetin 2 mg The intravenous M L D is 0 45 mg and 0 3 mg respectively, or in other words, as far as these observations go emetin is approximately 50 per cent more toxic than conessine

Modified Cholecystenterostomy —The following procedure is advocated by Fullerton The gallbladder is opened and cleared of its contents A light clamp is placed near the neck and the greater part of the viscus is removed The small remaining portion is anastomosed to the duodenum, so that when the operation is completed the cystic duct opens into the duodenum without the intervention of any sac which might harbor gallstones or regurgitated intestinal contents Just enough of the gallbladder is left to enable the anastomosis to be accomplished satisfactorily

What Is Heterophoria? A J Ballantyne —p 321
Fundamental Points in the Diagnosis of Pulmonary Tuberculosis J Crocket —p 329
*Tay Sachs Disease Symptomatology and Pathology of Three Atypical Cases H W Torrence —p 341

Tay-Sachs Disease —The cases described by Torrance being the youngest in the list most closely resemble the infantile Tay-Sachs group, with regard to the age incidence Histologically, they also resemble it, but possessing the typical pathologic picture of degeneration of optic nerves, nerve fiber layer, and ganglion cells (a triple syndrome) They present fewer additional variations to the accepted triple syndrome than the other cases Of these additional irregularities, most certainly the degeneration of rods and cones may be discounted owing to postmortem change and method of fixation In the elder cases (i e, Ichikawa and Wandless) the retinal destruction is most complete This may be due to the patients having lived longer than in the infantile group, and so allowing the final stages of degeneration to take place

Examination Into Degree of Efficacy of Antirabic Treatment W F Harvey and H W Acton—p 852

Visceral Infections by Fungi—The following cases are cited by Mackie one case of pulmonary aspergillosis complicating kala-azar, and two cases of streptothrix infection of the brain

Chemistry and Therapeutic Value of Anthelmintics—According to Caius and Mhaskar, salicylic acid has no anthelmintic properties, but esterification with methyl alcohol results in the formation of a compound with well marked vermicidal properties Esterification of either thymol or betanaphthol results in the loss of the vermicidal and vermifugal properties of those two very potent anthelmintics

Delayed Cures in Hookworm Infestation—In addition to its immediate vermicidal action Mhaskar says, an anthelmintic may also have a remote action on the worms This remote action brings about 'delayed cures" Except in proved cases of reinfection, a treatment which is known to be efficient need not be followed by any other

New Serum Test for Kala-Azar—The technic of the test described by Napier is similar to that described by Gate and Papacosta as the formol-gel test for syphilis, but the specificity of the test is in no way dependent on the gel formation but on the accompanying formation of a white opacity Napier terms this the 'aldehyde test" About 5 c c of blood is withdrawn from the patient's arm and allowed to stand for a sufficient time for the serum to separate One c c of clear serum is then placed in a small test tube ½ inch in diameter, to this one drop of 30 per cent liquor formaldehyd in the form of commercial formalin is added, the serum is immediately well shaken and placed in a test tube rack at laboratory temperature The serum from ar untreated case of kala-azar will immediately become viscid, within a minute or two it will have 'set,' so that the tube can be inverted without the serum being spilled, and will begin to become whitish and opalescent Within from three to twenty minutes, the time varying with different cases, the whole of the serum will have become absolutely solid and opaque like serum coagulated by heat or the "white' of a hard boiled egg If the serum is hemoglobin stained the coagulated serum will have a pink tinge which will turn chocolate brown after twenty-four hours

Formol-Gel Reaction in Leprosy—One hundred and sixteen serums from cases of leprosy not specially selected—nodular, anesthetic and mixed cases were included indiscriminately—were tested by Turkhud and Avari by the formol-gel method of Gate and Papacosta Every case gave a definite y positive reaction The test was carried out in every instance with inactivated serum only From these observations it appears that the Gate Papacostas reaction is likely to prove a valuable serologic test in the diagnosis of leprosy

*Malignant Melanoma of Gum M J Stewart and J Phillips—p 12
Agglutinating Serum for Certain Strains of Tubercle Bacilli J Smith—p 13
Diagnosis of Suprarenal Insufficiency S Wright—p 14

Etiology of Rickets—The observations on the etiology of rickets reported on by Chick et al disclosed that rickets developed during winter and spring under excellent hygienic conditions in infants receiving a diet composed of fresh milk from stall fed cows and to which sugar was added, and was prevented in the case of children receiving a diet containing cod liver oil, more milk, and less carbohydrate Both milks were low in vitamin A content Rickets did not develop in summer on either diet Rickets can be cured by codliver oil and by exposure to sunlight, or to the radiation of the mercury vapor quartz lamp The first six months of life is a period of special susceptibility to the onset of the disease Rickets may develop in an infant whose general condition is good or improving, and healing of the bones may occur independently of improvement in the general condition

Melanoma of Gum—Stewart and Phillips relate a case which is interesting as an example of melanoma arising in an unusual situation the alveolar margin of an edentulous upper jaw The patient's attention had only been drawn to the part ten days before she sought medical advice, and the denture itself was not roughened A small projecting spicule of bone was found at operation, growing from the jaw immediately beneath the tumor

Agglutinating Serum for Tubercle Bacillus—By injecting into rabbits a nonvirulent strain of living human tubercle bacilli in increasing doses at five day intervals, Smith secured a high titer serum After the sixth dose, the titer of the serum against the homologous strain was 1 1,600 Of eleven strains of human tubercle bacilli tested against the serum seven reacted to a 1 200 dilution, five to a 1 1,600 dilution

Diagnosis of Suprarenal Insufficiency—It is shown by Wright by an investigation of 100 healthy subjects that the white line of Sergent is a phenomenon occurring in a large proportion of normal subjects and is without pathologic significance A number of analogous physiologic responses are described The white line is not related to suprarenal insufficiency or to abnormally low systolic or diastolic pressure The white line is produced by local emptying of the capillaries from the active contraction of some elements in their walls, and is quite independent of the condition of the

arterioles A nervous mechanism of the nature of an axon reflex may be involved The bearing of this investigation on the clinical recognition of suprarenal insufficiency is discussed

Archives de Medecine des Enfants, Paris

*Foreign Bodies in the Duodenum V Veau and R Doubrere —p 321
Case of Lymphogranulomatosis H Barbier et al —p 338
Congenital Occlusion of Small Intestine A Rendu and P Wertheimer —p 349
*Acute Articular Rheumatism P Gautier —p 354
Crossed Intercostal Zona After Pleurisy G Schreiber —p 357
*Familial Hypertrophy of Bones Pleonosteosis J Comby —p 360

Foreign Bodies in the Duodenum—Veau exposed the duodenum of an 11 months infant who had a safety pin arrested at the spot the point upward He did not venture to cut into the duodenum, but merely manipulated it to dislodge the safety pin and squeeze it shut Attempts to force it along failed The safety pin was found in the stool the sixty-fifth day after the operation, the eighty-third after it had been swallowed He summarizes 21 operative cases from the literature, and 10 others in which the foreign body was found in the duodenum at necropsy The foreign body was a safety pin in only 4 of the cases and only 8 of the patients were children In 7 cases the duodenum was incised, with one death A gastro-enterostomy completed the operation in one case In the 6 cases with peritonitis already installed, 50 per cent died With infants, an incision across the fibers of the rectus gives more material for suturing Evisceration should be avoided in infants as this entails shock The suture threads should be left unusually long, up to twenty-one days The foreign body was worked back into the stomach in 6 cases with recovery in 4, in the fifth case the perforation of the duodenum had escaped detection

Complications of Acute Rheumatism—The boy of 6 was discharged the fifth week after the onset of acute articular rheumatism, during the course of which there had been endocarditis, pericarditis pleurisy and chorea He had been given 3 gm of sodium salicylate daily for two weeks and then smaller doses for ten days with digitalis and ice to the head as needed The only relic left of the whole is a mitral insufficiency

Familial Disease of Ossification—The family described here was reported by Leri last year, as summarized in THE JOURNAL at the time, Nov 5 1921, p 1526

Bulletin de l'Academie de Médecine, Paris

*The Soil in Tar Cancers G Roussy —p 617
Case of Adams Stokes Disease O Josue —p 621
Mechanism of Acceleration of the Pulse W Janowski —p 625

Uterine Fibromas—Tuffier insists that roentgen castration is contraindicated for women still in the child-bearing age He argues that enucleation should be given the preference always except when conditions otherwise justify hysterectomy The one great objection to enucleation has been the danger of recurrence, but now that irradiation can combat any recurrence, this objection is removed

Clamps in Abdominal Surgery—Abadie and Argaud used the Mayo and other clamps in their experimental research on dogs, and announce that the crushing—instead of killing the tissue cells, as they expected—seemed to inspire them to more active repair than when the tissues were merely sutured without being clamped The denuded portions healed over more rapidly Linen thread tore through sometimes but chromecized catgut 00 answered all requirements The Martel technic gave more regular and prompter results than the Mayo

The Soil in Tar Cancer—Roussy obtained tar cancers in 38 per cent of sixty adult mice by the end of 240 days Benign tumors had developed in 26 per cent, and 23 per cent had shown no signs of a tumor In nineteen of the sixty mice multiple tumors developed malignant in fourteen The difference in the outcome must be ascribed to the soil

Danger of Ordering a 'Twenty Thousandth Solution or the Like J Janet —p 367

Reflex Phenomena of the Genito-Urinary Apparatus—Bartrina reported last year a case in which the abnormal position of one kidney checked the functioning of both kidneys, and the menacing uremia was cured only by removal of the malplaced kidney But the other kidney is not the only organ that suffers from an inhibiting reflex starting in the urinary apparatus The genital and the digestive apparatus may feel the effect, as also the other elements in the urinary system Among these reflexes, pain or tenesmus in the bladder early in renal tuberculosis is exceptionally instructive Disturbances in the urethra and prostate are common with calculi in kidney or ureter This 'false urethritis" with unsuspected calculi in the kidney often proves misleading There is pain or smarting in the urethra, and there may be secretion, but the gonococcus is not found The ordinary bacterial flora may then set up inflammation, or the local treatment applied on a mistaken diagnosis may start it

The neuralgia character of the pain stamps these reflex cases as a group apart They persist refractory to treatment until the calculus ceases to give further trouble Pain in kidney or urethra may be noted in gout, diabetes, phosphaturia, etc, probably from some old damage of the kidney with which it still has to contend The kidney often suffers in the uric acid oxalic acid and other diatheses There may be no symptoms in the kidney itself, but its intimate nervous connection with the genital apparatus may readily explain certain instances of impotency, spermatorrhea, and other functional disturbances, as of reflex origin Intestinal disturbances traceable to reflex action from unsuspected kidney stones range from simple constipation to pseudo-occlusion and spasmodic pains One of his patients with known kidney calculi sometimes had to take enemas a dozen times a day to relieve his returning colic Another barely escaped a laparotomy for ileus by the discovery of a few erythrocytes in his urine In all these bowel cases the complete cure followed the clearing out of the calculi from the kidney Pain spreading from the bowel to the rectum and anus is particularly suggestive of a kidney calculus Injection by the rectum of an anodyne relieves the pain with true kidney colic better than by ingestion or hypodermic

Renorenal Reflex—Lanzilotta reports five cases in which the pains from a diseased kidney were localized exclusively in the other kidney which was sound After removal of the calculi or of the whole kidney, there was no further pain on the other side

Profuse Hematuria with Hydronephrosis—Five cases are described They had mostly been mistaken for cancer, but recovery followed nephrectomy

Cystoscopy in Chyluria—The cystoscope revealed that the chyluria was not as independent as assumed In the three cases described, treatment with hexamethylenamin and uva ursi was followed by an exceptionally rapid cure

Manual Treatment of Functional Spasms L Durey —p 709
The Dose in Radium Treatment R Weill —p 714
Electrotherapeutics in Constipation A Berthomier —p 719

Radiotherapy—Zimmern exclaims that every day is recording new progress in technic, in diagnosis, in therapeutic application of radiant energy, so that radiology is establishing more and more its position as one of the strongest pillars of the medical sciences The deep roentgen ray treatment is nothing new he says, but the logical development of our knowledge of the properties and biologic action of the roentgen rays In pruritus and radicular neuralgia roentgenization of the roots involved, where they emerge from the spine has cured in a number of rebellious cases as also in radiculitis of the sciatica or lumbago type With deep roentgen therapy, there seems to be an optimal dose for each kind of affection, but this may vary with the individuals in each class In diagnosis, Sicard obtained instructive findings by injecting an opaque iodin compound into the epidural space or spinal canal as it worked its way into the sacral culdesac For pyelography, a 30 per cent solution of sodium bromid *has been found efficient, while it has the advantage of being* nontoxic

Hydrarthrosis of the Knee—Hirtz relates that a prompt cure was effected by roentgen exposures plus static electricity in all but one of twenty-four cases of acute or chronic hydrarthrosis, and great improvement was realized even in this one case A tuberculous element is probably responsible for the partial failure in this patient The list includes several cases of gonococcus origin

Prophylaxis of Electric Accidents—Zimmern urges that children in school should be systematically taught the danger of placing the hand on a gas or water faucet when an electric wire is held in the other hand

Electricity in Treatment of the Urethra—Heitz-Boyer recapitulates the many uses for static electricity, diathermia spark treatment, *etincelage,* in acute and subacute affections of the urethra, and in sclerosis by *etincelage* or electrolysis and in destroying polyps and other mild tumors In short he adds, there is scarcely any lesion in the urethra that is not amenable to some form of electric treatment

The Galvanopsychic Reflex—Lahy discusses the differences in the galvanometer readings when connected with a human body and generator The resistance of the body to the electric current varies even with mere emotions and this galvanopsychic reflex is thus one of the most sensitive means at our disposal for investigating emotion It is significant that the response is most pronounced when the electrodes are placed on a region where sweat glands most abound

Burns and Their Treatment. A Kotzareff —p 5
Angles of the Colon in the Fetus and the Newly Born P Descomps and R Ducastaing —p 30
Dead Bone Implants C Girode —p 60

Burns and Their Treatment—Kotzareff recalls that animals die from burns just the same whether the nerves innervating the region have been severed or not They succumb to poisons generated in the burned tissues unless they can manufacture antibodies or have them supplied from without promptly enough to annul the toxic action Serum from a guinea pig that had been burned, and had produced antibodies, when injected into another guinea-pig protected it against fatal harm from a burn experimentally induced afterward, even when more than half of the body was gradually subjected to a burn of the third degree Fourteen series of experiences in this line are reported, with other data which all demonstrated, he says, that serotherapy is capable of warding off the toxic action from a burn the toxemic shock, which is the main factor in the fatal outcome of burns He urges the systematic production and use of an antiburn serum It can be obtained from patients convalescing from burns or can be prepared from animals Two clinical cases are described in which the recovery of the boys of 8 and 5½ is ascribed to the intramuscular injection of 5 or 8 c c of serum from other children convalescing from burns The reaction to a severe burn is manifest in fifteen minutes by the eosinophilia in the lungs This is not special to burns, being found in all endogenous and exogenous intoxication from destruction of animal tissues This destruction, however, entails an immunizing process in time, and this we can hasten by injecting an antiburn serum The question now is merely the production of an antiburn serum so it can be readily available at all times

Disadvantages of Dead Bone Implants—Girode writes from Delbet's surgical service to describe the experience with a dead bone implant in treatment of fifteen cases of pseudarthrosis or fracture of the neck of the femur The bone was taken from the tibia or the ulna of just slaughtered cattle and was kept in alcohol The results were extremely unsatisfactory for a number of reasons Delbet has returned to his former method of taking a strip from the patient's own fibula for the purpose without periosteum

Recurring Inguinal Hernia Oudard and G Jean —p 143
Mixed Tumors in the Parotid Region E Forgue and G Roux —p 181

Recurring Inguinal Hernia—Oudard and Jean tabulate from the navy surgical records 145 out of a total of 183 cases of known recurrence of inguinal hernia after operative treatment The recurrence was external oblique in 131 instances direct in 13 and internal oblique in only one case No method of treatment was exempt from recurrence, even when done under the most favorable auspices These experiences teach the necessity for supporting the wall after the primary herniotomy if the tissues are exceptionally flabby, not with a pad merely an elastic band The sac should always be amply opened up to see that there is no adhesion, and any epiploic fringe should be resected The percentage of recurrence with the various methods of operating ranged from 1 to 10 per cent The number of recurrences with the Bassini operation have convinced them that this method should be definitively abandoned The Championniere method is as good as the most complicated for ordinary hernias of the congenital type with a long narrow canal With hernia of other type they commend a modification of Halsted's first method

Mixed Tumors of the Parotid—Forgue and Roux review twenty two cases

Pseudocyst in the Radius L Baccarini —p 233
Accessory Interrenal Body Removed at Herniotomy U Stoppato —p 253
Chronic Primary Pancreatitis D Calzavara —p 262
Limits of Prostate Operability G Roello —p 289
Tuberculous Peritonitis C Decio —p 311

Pseudocyst in the Radius—The head of the radius was resected in the boy of 6 and the findings suggest that some injury of the vessels had allowed the escape of blood into the bone these repeated small hemorrhages prying apart the lamellae They drop into the marrow cavity and are absorbed This sequence may occur from trauma, but more often it is the result of some toxic or developmental anomaly of the artery wall This explains best the gradual regular increase in the size of the cystic cavity Scraping out the cyst removes the altered bone tissue and the abnormal vessels and leaves a clean cavity and there is a chance it will fill up with normal compact bone These pseudocysts appear during the period of most active growth of the long bones, and in the region of the bone close to the epiphysis, where the growth process is most active The lesion is usually single and is cured by simple curetting, if the safeguarding of the region can be counted on during the months of the repair process

Chronic Pancreatitis—Calzavara relates that the woman of 31 after a hearty meal, experienced a sudden intense pain in the epigastric region which did not spread The pain ceased suddenly and spontaneously in two hours, but it

returned again for seven days, either from two to four hours after eating, or during fasting There was no vomiting, fever or jaundice There was a free interval for three years, and then the pains returned as before, recurring during two weeks A year later they reappeared for three and later for seven days, the interval finally becoming only one month At the last attack there was vomiting and a slight tendency to jaundice An operation showed a chronic, evidently primary, circumscribed interstitial inflammatory process in the head of the pancreas He did not attempt resection, and merely provided an ample outlet for the bile by suturing the fundus of the gallbladder to the anterior wall of the stomach in the prepyloric region There has been no return of the disturbances during the more than a year since and the general health has been perfect The case confirms that a primary pancreas disease may simulate gallstone colic The lack of spreading of the pains helps to differentiate the pancreatitis There were foci of fat necrosis in the omentum in this case, with atrophy of the adipose tissue with polyblastic infiltration

The Limits of Operability with Prostate Disease—Roello analyzes 520 operative cases of hypertrophied prostate in Lasio's service since 1909 With the Freyer operation, 469 were cured and fifty-one died, but the mortality has been constantly declining, from over 14 in 1909 to 4 55 per cent in 1921 There are no contraindications to the Freyer operation he says, except grave valvular or heart disease with lost compensation, or tabes or myelitis interfering with the innervation of the bladder or extreme wasting disease or acute infectious disease Under all other conditions the operation at one or two sittings has every prospect of success

Surgical Treatment of Tuberculous Peritonitis—Decio relates that 19 are still living of the 31 operative cases he describes in detail The outlook seems to be promising for a combination of radiotherapy or heliotherapy with operative measures In over two thirds of the cases the peritoneal tuberculosis subsides after the laparotomy, especially the serous form of tuberculous peritonitis Of course, the patient may succumb to tuberculous lesions elsewhere, after clinically normal conditions have been restored in the peritoneum He analyzes recent literature on the subject The 31 cases cited are the only ones he has been able to trace of the 50 operative cases during the last ten years in Ferroni's service at Florence The patients were all women between 22 and 55 except 2 girls of 15 The age seemed immaterial for the results, as also whether a drainage tube was left or not In his latest series he closed the abdomen completely after the exposure of the peritoneum to the light and air during the laparotomy He compares the various theories that have been advanced to explain the action of the simple laparotomy, inclining to ascribe the effect to the 'modification of the humors" by the operation

*Indol in Pulmonary Disease O Cantelli—p 481
*Evils of Taxis for Hernia R Botteselle—p 483
*Hydatid Cyst of Liver O Cignozzi—p 485
Primary Soft Chancres on Tongue G Martini—p 490
Preventive Treatment of Neurosyphilis G Pellacani—p 491
Lumbago and Sciatica E Arevoli—p 493

Formation of Indol in Destructive Pulmonary Lesions—Cantelli's research on rabbits in 1915 confirmed that indol was excreted through the skin after injection of indol His research here reported on patients with pulmonary lesions apparently establishes that indol in the breath and in the sputum is a sign of a suppurating and destructive lesion in the lung It was never found with pulmonary or bronchial lesions not accompanied by suppuration, and it seems to be responsible for the fecaloid odor in the destructive process Indol in the urine warns of a suppurating and putrefying process somewhere in the body

Evils of Taxis of Hernia—In the case reported, the strangulated hernia was reduced by taxis without the strangulation being corrected or even suspected This is the great danger of taxis except as a preliminary when all is prepared for an operation In this case the man was a deafmute, and the symptoms of ileus were all that was known of the circumstances

Operative Treatment of Echinococcus Infection of the Liver—Cignozzi reports 2 deaths and 3 cases of recurrence in his 50 operative cases of hydatid cysts in the liver and 8 in the lungs In 4 other pulmonary cases, no operation was attempted This experience has demonstrated the advantages of suturing the cyst to the abdominal incision, with capillary drainage The extensive defect left can be readily corrected with a plastic operation In one case in which the hepatostomy opening is illustrated, the cyst measured 16 cm in depth Notwithstanding this large size, the cyst was easily reached through a parirectal incision and marsupialized The cyst cavity is packed with dry gauze for ten days and then with gauze dipped in an acid alcohol solution The cyst membrane shrivels and is cast off spontaneously in from eighteen to twenty days The temperature usually runs up after the fifth or six day, from resorption, but returns to normal after the membrane has been cast off The gauze aids in stimulating granulation so that the healing is complete in from seven to eighteen weeks A plastic operation to close a large defect has been applied in 140 cases, and always with most satisfactory outcome The fluctuation is rendered evident as the patient lies on his side on the table or bed, without a pillow and the physician places his right fingers on the lower part of the liver region while with the other hand he depresses the wall, 4 or 5 cm above telling the patient not to breathe By this means a wave of fluid can be dashed back from hand to hand, a constant and pathognomonic sign of the cyst below The cyst tends to spread forward wherever its origin Eosinophilia is found in 60 or 80 per cent of the cases, and the intradermal reaction in 90 per cent but the fixation of complement test is positive in about 93 per cent The urine sometimes contains albumin and tube casts

*Early Diagnosis of Apical Disease I Jacono—p 529
Surgical Treatment of Tabetic Gastric Crises D Giordano—p 530
Epigastric Pain with Hemoptysis C Cantieri—p 531
*Spastic and Plethoric High Blood Pressure C Trunecek—p 534
*Inheritance of Disease P Mino—p 535

Early Diagnosis of Apical Disease—Jacono adds palpation through the axilla to Boeri's four signs of incipient apical disease namely, the auscultation findings after massage of the apex, tenderness of the chest wall in the apex region, defective or excessive development of the muscles in the region, and the pupil phenomena Jacono pinches the muscles through the intercostal spaces, in and below the axilla, on both sides In health this gentle pinching is scarcely noticed but with apical disease below, it causes lively pain If the glands feel large and tender, this is further evidence of a lesion in the apex These changes might be explained by toxic neuritis, reflex neurotrophic disturbance, or involvement of the pleura

Surgical Treatment of Tabetic Gastric Crises—In Giordano's patient the gastric crises were essentially motor disturbances, and he severed the vagus at the diaphragm, supplementing this with gastro-enterostomy and dilaceration of the sympathetic fibers accompanying the celiac trunk nerve The young woman had been confined to bed for a year, the gastric attacks returning every two or three weeks, and lasting from three to ten days The rebellious vomiting had sapped all her strength After a two months' interval, the vomiting attacks returned, but the food was passed on and retained, and the attacks could be arrested with chloral Of late they have been growing less severe and less frequent, but pains in the legs have been growing more severe

Epigastric Pain with Hemoptysis—Cantieri warns that this combination of blood issuing from the mouth and pain in the epigastrium is liable to be mistaken for a bleeding ulcer in

the stomach or duodenum In one young woman, intermittent epigastric pain, tenderness, dyspepsia, and blood issuing from the mouth accompanied the menstrual periods Finally rales and blood streaked sputum corrected the diagnosis In another case the epigastralgia and dyspepsia were not accompanied by any signs of tuberculosis, but the conditions under which the hemorrhage appeared testified to its hemoptysis nature, corroborated by the ultimate fatal course of the case The epigastralgia disappeared after a few months The solar plexus evidently suffers from the tuberculous toxins and decalcification This plexus is also liable to be compressed by tuberculous suprarenals In another case, the patient was sometimes waked in the night by blood in her mouth and a tickling in the throat, occasionally this occurred in the daytime An apical affection had been diagnosed, but the persisting good general condition during the year finally led to search elsewhere, and a varicose vein was found in the throat The young woman was hysteric and had varicose veins on the legs and varices in the vagina When the temperature rises and keeps high after the hemorrhage, this tips the scale in favor of a tuberculous process The lack of physical symptoms should not mislead the physician Blood in the stools is *no criterion, as blood from the lungs may be* swallowed Radiography may give the clue when all else fails The gastric pain in these hemoptysis cases may deceptively simulate the classic pain with gastric ulcer He warns against the unconscious tendency of the patient and family in such cases to mislead the physician away from the idea of the more serious lung disease, by emphasizing the gastric ulcer features of the case

High Blood Pressure—Trunecek discusses the type in which the high blood pressure is the result of spastic contraction of certain parts of the blood vessels, and the type for which a plethora of blood is responsible In both these forms, food that leaves toxic waste should be avoided, and hygiene in general enforced If this does not cure, then the acids in the blood should be neutralized with a harmless alkaline solution For this he commends the fluid known as Trunecek's serum It is a combination of all the alkalines normally in the blood serum, and in the same proportions From five to ten injections, each of 2 or 5 c.c of this repeated twice a week are generally successful In older persons with long chronic high pressure of these types, the course must be longer In prophylaxis, a course of chlorid and bicarbonate mineral waters, once or twice a year for two or three weeks, and iodids to promote oxidations may be useful, with Trunecek serum at need

The Mendelian Laws in Inheritance of Disease—Mino remarks that at present all that can be done is to accumulate data in this line, for the deductions of a following generation But the individual must compile the data with criteria and methods which will render their utilization possible

*Bio ociologic Progress in the Americas R. J Fosalba—p 111
Stenosis of Larynx Following Smallpox A Flores—p 136
Amebic Interstitial Hepatitis C Monge—p 139
The National Public Health Service in Peru—p 157

Synthetic Program for Biosocial Research—This is Fosalba's inaugural address on election to the Academia de Medicina of Peru He states that the compulsory physical training which was introduced in Uruguay fifteen years ago has already increased the average height of the young by 17 mm Up to 15, the height surpasses that of corresponding ages in Europe and the United States He adds that Uruguay has made a greater reduction in the death rate from tuberculosis than has been realized in European countries The efforts have been concentrated mainly on the "pretuberculous," striving to eradicate the predisposing factors He describes what has been accomplished to date in concrete biosociology in the Latin American countries and the results of his own investigations

Amebic Hepatitis—Monge classifies hepatitis in six groups, the acute, the jaundice-inducing, the chronic, the tuberculous, the syphilitic and the toxic He describes a case of acute interstitial hepatitis in a man of 32, who had lost 30 pounds in weight during the eight months of agonizing pains in the enormously large liver Repeated punctures were negative, and cancer of the liver had seemed certain Notwithstanding the absence of amebas in the stools Monge gave tentative emetin treatment and a complete cure followed in less than a month Before the end of the month he found some encysted amebas in the stools He does not know of any similar case on record of amebic hepatitis, simulating cancer

The Problems Before the Public Health Service in Peru—This is the letter of acceptance of Dr Henry Hanson, an officer of the United States Public Health Service when he was recently appointed chief of the national public health service in Peru

Stigmata of Chronic Gonorrhea in Women L del Portillo—p 113

The Stigmata of Chronic Gonorrhea in Women—Portillo gives a list of seven stigmata liable to be found in the vulva of women who have had gonorrhea at some time, six in the vagina and four in the urethra He lists among the vulvar stigmata adhesion of the opposite walls This is very rare, it follows only severe inflammation Papillary excrescences may be found in the vulva vagina or urethra and although these may be due to other causes yet the presumption is in favor of irritation from chronic gonorrhea as a rule Cysts in the wall of the vulva or vagina can be felt as small torpid bunches never causing pain but they may grow to quite a size and they may become infected and rupture They must not be confounded with bartholinitis Hyperesthesia of the vulva and hypertrophy of the walls of the vulva and vagina are further suggestive as also narrowing of the passage in either a phlegmon in the vaginal wall and vaginism Partial stenosis of the vagina or urethra is also suggestive of irritation from chronic gonorrhea The relics of gonorrhea in the uterus and adnexa are familiar to all from metrorrhagia cysts adnexitis refractory to vaccines, and sterility to the complications of childbirth

Arterial Anesthesia—Calcagno trephined an osteomyelitic focus in the tibia of a boy of 16 under the anesthesia induced with 0.2 gm of stovain in a 0 5 per cent solution, injected directly into the femoral artery through the skin He sometimes expels the blood from the limb by winding it from the toes to the root beforehand In one man of 52 the anesthesia was complete with only 0 12 gm of procain allowing amputation of the leg for syphilitic gangrene He describes a number of other major operations on the legs done under arterial anesthesia For the arm, it is safer to expose the artery before making the injection, or a retrograde injection might be made in the radial artery The only contraindication is infection in the region where the artery is to be injected The needle hole closes spontaneously afterward

Bacteriophagia—Pico's experiments are the first to be recorded he says in which the bacteriophagic action was induced with pancreatin, trypsin or papain instead of a filtrable virus as in the experiments of others The bacteriophagia is thus a transmissible autolysis of micro-organisms, accelerating the normal autolysis of the bacteria The regeneration of the lytic principle at the expense of the disintegration products of the bacteria explains the serial character of the autolysis This, he explains may serve as the basis for a new bacteriologic therapeutics, a lysinotherapy, based on a more general conception of the bacteriophagic phenomenon than d Herelle visioned

Chronic Hydrocephalus in Children—Cassel has found the prognosis of syphilitic hydrocephalus, as a rule, unfavorable. A number of children succumb to the cerebral symptoms without securing any benefit from energetic antisyphilitic treatment. A complete cure is rarely accomplished. Most patients retain at least mental defects that are more or less marked, many become grave neuropaths that are a great burden to their family. However, in spite of the unfavorable prognosis in most cases, in no case should energetic treatment be neglected.

The Iodin Content of Drinking Water in Relation to Goiter—Miesbach has conducted investigations in Bavaria which lead him to believe that the lack of iodin in the drinking water in certain regions may possibly be the cause of the increased incidence of goiter in those sections.

Sterility in Women—In the course of this dissertation on the prospects of treatment of sterility, Schmidt says that when stenosis of the cervix seems to be responsible for the sterility, the best results have been attained by Fehling's rinsing treatment. A fenestrated glass tube, the size of a lead pencil and about 5 cm. long, is introduced into the cervix. It is slightly curved, and a glass plate prevents its slipping into the uterus. It is worn for three days, and then the uterus cavity is rinsed out with a 1 per cent. solution of liquor formaldehydi. The tube is replaced for three days, and this is repeated two or three times, rinsing the uterus in this way at each change. This induces a moderate astringent action on the mucosa and the os is mechanically and permanently en ed, and the uterus accustomed to mechanical irr tation. regnancy followed in a recent series in 27 per cent. of tl fifty-six cases, and in 35 5 per cent. of another series of thirty-one cases.

The Initial Pains with Ulcer—Jonas' analysis of a long series of cases demonstrates that a sensation of oppression or cramp occurring in the stomach daily or almost daily for weeks, showing some connection with intake of food, and followed by long periods of freedom from disturbances, the whole displaying a seasonal character, suggests incipient gastric or duodenal ulcer. A period of excessive peristalsis precedes the actual ulceration in stomach or duodenum.

Treatment of Swine Erysipelas in Man—Gestewitz concludes from six cases of this kind that the disease in man is comparatively mild and local. It may heal under ordinary salves, but if not, the antiserum should be administered. In one of his cases certain general symptoms followed the eating of the well cooked meat of the diseased hog, but it is a question whether they were referable to serum sickness or to food anaphylaxis.

Cultivation of Tubercle Bacilli—Meyer and Fitschen report almost invariable success with the Dorset egg culture medium, shaking up the yolk and white together, and adding one-fifth part of water, and slanting the test tube in the incubator till it hardens. The usual preliminary treatment with an alkaline caustic kills off the accompanying bacteria. They close the tube with paraffin and stain a smear from the culture the fourth day, and every two or three days thereafter.

Thallium a Specific Poison for the Endocrine System—Young rats fed with bread dipped in a 1 5,000 solution of thallium acetate lost all their hair in a month. The growth was stunted, and the animals presented a cretin-like appearance. When the drug was injected, the toxic action was pronounced and often fatal. The endocrine glands showed a selective toxic effect, and the whole organism suffered secondarily through intermediation of the ductless glands. Buschke and Peiser do not know of any other substance that acts thus almost exclusively on the endocrine system. Experiments on tadpoles with thyroid treatment to counteract the thallium, and experiments on the frog heart have been confirmatory.

Treatment of Convulsions in Children—Blühdorn recalls that the convulsions of spasmophilia occur scarcely ever outside of the winter and spring, and that breast-fed infants escape as a rule. Infants overfed with milk, with a tendency to hard stools, are the predisposed, rachitis and spasmophilia have much in common. Overheating and prevention of radiation of heat are also liable to induce convulsions. An ample supply of fluids is imperative, poured into the stomach or rectum or infused subcutaneously. If chloral fails to relieve the spasmophilic convulsion, there is probably some organic cerebral process. Calcium treatment combats the spasmophilia effectually and the child can be fed as indicated. He prescribes it in the form of 10 parts calcium chlorid, 2 parts anisated solution of ammonia, 1 part gum acacia, saccharin to taste, and water to 200 parts. The dose is 10 c.c. six or eight times a day at first and then three times a day, kept up for a long time. Spasmophilia may accompany and aggravate organic disease, as in a recent case of convulsions in whooping cough. The electric and other tests were negative, and the convulsions seemed to herald the fatal termination. As a last resort, 20 c.c. of an 8 per cent. solution of magnesium sulphate was injected, and the benefit was amazing. In all organic cases, therefore, it is well to give tentative treatment for possible spasmophilia, to eliminate this factor, at least.

Protein Therapy—Voehl's summary of recent literature on parenteral protein therapy mentions chronic joint affections

and skin affections as the fields in which this method of treatment is proving most effectual Although there is no general agreement, yet the testimony already available is very encouraging, although we must not forget, he adds, that, with any new treatment, the favorable results are more liable to be published than the unfavorable

Payr's Lymph Drainage in Elephantiasis Cruris—Haubenreisser reports two cases of elephantiasis cruris in one of which lymph drainage by the Payr method accomplished a complete cure and another case in which the same method brought about an almost complete cure

Gradual Dilatation of Stricture of Urethra—Hammesfahr states that in two cases of extreme narrowing of the posterior portion of the urethra following, in one instance an operation and, in the second instance, trauma, he was able to effect a cure by passing a small ureter catheter or wire by way of the cystotomy wound through the bladder into the urethra By this "endless" method he was able to pass rubber tubes of increasing caliber

Recurrences Following the Bassini Operation—Schwartz discusses a series of 500 operations for inguinal hernia by the Bassini method In 207 cases in which reexamination was possible after from one to eleven years, there were eleven recurrences, or 5.3 per cent Other series refer to from 10 to 20 per cent recurrences He describes the slight modification of the Bassini method that Friedemann employs

Ovarian Therapy in Climacteric Toxicodermias J Hofbauer —p 558

New Basis for Cancer Statistics—The introduction of roentgen and radium therapy has made it necessary to adopt entirely different rules for cancer statistics, it being especially important that new statistics make possible a comparison of the results of operation with the outcome of irradiation Winter has drawn up a carefully worked out scheme for statistics on the modern cancer problem He gives the outlines of his plan

Speed of Sedimentation of Blood Corpuscles—Linzenmeier emphasizes again the diagnostic value of the determination of the suspension stability of blood corpuscles in gynecologic practice If the sedimentation time is accelerated, that is, if it is less than thirty minutes acute inflammatory processes affecting the genital organs may be suspected The changes in the sedimentation velocity will often furnish desired information when changes in the temperature leave us in the lurch In the differential diagnosis between recently disturbed ectopic pregnancy and acute adnexal and peritoneal affections slow sedimentation points with a high degree of probability to tubal pregnancy Sedimentation serves also as an excellent indicator as to the time for operative intervention in fixed retroflexion, chronic adnexal tumors and similar affections If sedimentation occurs in less than one hour virulent infective agents may still be present and we had better wait with the operation, if sedimentation requires two hours or more it is safe to go ahead with a laparotomy latent infection need no longer be feared The buffy coat or crusta phlogistica of the physicians of earlier centuries has again come into honor through Fahreus' revival of a well known diagnostic principle

Action of Procain on Muscle Tonus S de Boer —p 1621
*Flatfoot D Brocx —p 1627
Ovarian Metastasis of Cancer J A van Dongen —p 1630

Standard of Nutrition in Children—Van der Loo gives the formulas for the ten different methods in vogue for assessing the physical fitness of children and points out the fallacies of all of them from Pirquet to Dryer He then describes his own method which he affirms, comes nearer to the ideal than any of the others for sifting out the undernourished It is based on a standard table showing the normal weight and chest measure for a given height The difference between the chest measure and the normal figure is multiplied by —2.5 for each centimeter, and the difference in weight is multiplied by 4, 3 or 2 for each kilogram His table is made up from several thousand normal Amsterdam children His index is 100 times the weight divided by the square of the diameter of the chest multiplied by the height The circumference of the chest is 3.75 times the diameter He explains,

for example, that a child 114 cm tall, with a chest measure of 54 cm, weighs 16 6 kg The normal figures he gives for a child 114 cm tall are, chest, 55 6 cm, and weight, 19 2 kg The child is thus 2 6 kg too light and its chest 1 6 cm too narrow Multiplying —2 6 by 4, and adding —1 6 multiplied by —2 5 = 6 4 We thus get $\frac{64}{4}$ = 16 kg as the loss from underfeeding and 2 6 —1 6 = 1 kg the loss in weight from the narrow chest

Prophylaxis of Flatfoot—Brocx has been impressed in his sixteen years of sickness insurance practice with the number of cases in which flatfoot develops after some accident to the foot or sickness confining to bed for a time When the patients get up after this, flatfoot develops He ascribes this insufficiency of the foot to the weakening of the muscles from disuse, but above all to the fact that when the patient gets up, he wears loose, old shoes or slippers at first The weight-bearing, with the muscles thus weakened, invites flatfoot, but it can be warded off by having a special supporting sole in each shoe Walking is the best exercise to restore normal tone to the muscles, but until this is realized, the arch of the foot should be supported

Case of Abdominal Contusion A F Nordholt —p 1704
Intragluteal Injection of Turpentine in Treatment of Gonococcus Arthritis K A Rombach —p 1707

Bacilli Carriers—Aldershoff warns that in the attempt to detect bacilli carriers and bacilli holders it is very easy to overdo, and bring discredit on preventive medicine in general He advises to restrict the search to the cases in which the epidemiologic findings indicate a carrier of virulent germs It should then be legally possible to take the necessary measures Their aim should be to keep the carriers and holders out of occupations in which the danger for others is especially great Until we know of some simple and reliable method to distinguish between virulent and nonvirulent germs, there is no use or sense in wholesale examinations on a large scale for carriers"

Treatment for Hemoptysis—Geers is chief of the public sanatorium at Joure, and until 1917 had usually from 18 to 24 severe cases of hemorrhage from the lungs each year, with more than twice as many mild cases, and there was always at least one fatal case of hemoptysis during the year Since that year he has not had a single case of hemorrhage from the lungs, and he ascribes this success to the practice then introduced of giving milk by the rectum, as a readily absorbable solution of calcium Milk by the mouth clots, and its salts cannot be readily absorbed Solutions of calcium salts given internally or subcutaneously often fail The milk enema was the last resort at the twenty-third hemorrhage in his first case, after failure of the whole arsenal of other measures There seems to be a certain periodicity about hemorrhages from the lungs and by study of the pulse, the filling of the blood vessels, the color of the face, the size of the pupils and the subjective symptoms, it is not difficult to tell when hemoptysis is impending Then he begins at once with the enema of 250 gm of tepid milk every evening, having it retained as long as possible All the milk in the institution is always heated to 90 C The enema may be given mornings, too, if necessary In special cases a subcutaneous injection of gelatin may be advisable, but he has not found this necessary more than twice in the last four years He has had no opportunity to try this treatment in hemophilia, but it proved useful in a bleeding gastric ulcer case He advises the practitioner to inject the gelatin first and then follow with the milk enemas He warns against morphin as inviting aspiration pneumonia after hemoptysis

Therapeutic Inoculation with Malaria in General Paresis—Gans reports the application in nine cases of general paresis of Wagner-Jauregg's method of inducing a fever by inoculating with malaria It has been described as a system of therapeutic "driving out the devil with Beelzebub" Gans' experience was favorable, confirming Wagner's statements The effect in three of his cases, he says, was remarkable, the others were too far advanced for any hope of benefit In a comment on this article by G C Bolten (page 2107) he mentions that he had two patients with general paresis who had fever from tuberculosis, but this fever did not modify their general paresis He also mentions that in the East Indies malaria is common in Chinese workmen, but they often develop general paresis and tabes

The More Recent Literature on Rachitis L Havinga —p 1793
A Pioneer Insane Asylum 1442 H Schade —p 1803

Diagnosis of Pulmonary Tuberculosis in Children—De Lange deplores the too frequent tendency of practitioners to decide that in a child, with a tuberculous lesion anywhere, a process in the lung must necessarily be of a tuberculous nature Even chronic lung processes with negative tuberculin tests are regarded as tuberculous, when in fact there is merely some infiltration and tendency to bronchiectasia As the lung clears up in time, the case is reported as an example of a brilliant cure under the treatment that had happened to be used at the time It is a grave blunder to send such children to a tuberculosis sanatorium A child under 8 with physical findings of such extent would rapidly succumb, if they were actually of a tuberculous nature There may be a small tuberculous focus with an encircling nonspecific infiltration The French "splenopneumonie" is one form of these chronic nontuberculous affections of the lung in children A chronic pneumonia may entail retraction, and in asthenic children the right subclavicular fossa is often sunken in Apical processes are rare in children, while a faulty attitude may induce deceptive physical findings The difference in the size of the two lungs may also prove misleading Extensive chronic lung processes in children under 8, which clear up or remain stationary, are not pulmonary tuberculosis She describes several typical cases in which only the ultimate recovery corrected the diagnosis

Phlegmonous Conditions in Digestive Tract R Roman —p 433

Phlegmonous Inflammatory Conditions in Digestive Tract—Roman gives the tabulated details of 271 cases that he has compiled, and tabulates separately the group of 41 cases in which the intestinal wall was involved In the 41 intestinal cases, 9 were saved of the 12 treated by radical operation, but all died under medical treatment or palliative operation alone Fourteen cases were in the duodenum, all fatal, but one patient was cured by resection of the bowel involved in the 6 jejunum cases, and 6 of the 8 ileum or cecum cases Two others were cured by resection of the colon MacCallum, Dowd and Taylor-Lakin are the only Anglo-Saxon surgeons cited Death occurred in twenty-four hours up to thirty-nine days, the average duration being from two to five days In a case personally observed, the acute phlegmonous sigmoiditis proved fatal in one week In a second case, the phlegmonous inflammation extended over a long stretch of the ileum, and the man of 25 recovered after this segment had been resected The sudden onset of diarrhea, without pains, in the first case, contrasted with the severe colic pains and chills in the second case, without diarrhea or vomiting The young man returned to work for four days, but the pains and tenderness kept up and a laparotomy on the presumptive diagnosis of appendicitis revealed the phlegmonous changes and allowed the complete cure Both the men had been supposedly in perfect health before In the total 271 cases, 180 were men and 73 women, the sex of the others was not specified The mortality was 91 2 per cent in the 217 cases of phlegmonous gastritis, but was 100 per cent in the sigmoid, transverse colon duodenum and esophagus cases The acute onset and rapidly severe general symptoms are common to all localizations, and there seldom had been any symptoms before to call attention to the digestive tract

SOCIALISTIC TENDENCIES IN MEDICINE *

JAMES A GARDNER, M D
BUFFALO

It is not my object to decry the benefits to humankind and to civic life which have come from some of the progressive movements brought about by sincere effort, but, in recent years, under cover of promoting the welfare of society or some part of it there have been permitted to be inaugurated many so-called reforms which, in reality, are little more than the outcome of the emotional desires of restless faddists or of the ideas of extreme and radical discontents

The contention is sane that all reforms of whatever nature should be made only after patient and scientific investigation of the causes and the cure of the evil sought to be corrected, and that the desire to bring about such reforms presupposes knowledge obtained by serious investigation and careful research, unhampered by emotion or prejudice

It is not an exaggeration to state that, in many instances, sincere and enthusiastic advocates of social and welfare legislation, so-called, are not familiar with the full purport or essential details of the measures they advocate It is not at all uncommon for boards of directors or other governing bodies, after a few moments' consideration, to announce support or opposition to legislation which has required weeks of study by men conversant with the subject before they are willing to pass judgment upon it Propagandists, through well-meaning people, have been doing much work among our law making bodies which, in the near future, will have to be undone

PROPAGANDISTS IN THE FIELD OF MEDICINE

The field of medicine has been a fertile one for the agitator and the propagandist The physician has always been ready to aid in measures for the betterment of humanity It is fair to assert that no other profession has been so lacking in self-interest It is perhaps due to this willingness to help in every movement for physical and moral advancement that the reformers and uplifters have been allowed to invade, unopposed, the practice of medicine and surgery, until the time has arrived for raising the danger signals The peril of the situation becomes more urgent when it is realized that the public is being educated to believe that the socialization of the medical profession will bring higher standards of health The fact is that, with the initiative and individuality of the physician removed the profession will cease to attract to it men of energy ability and ambition, who are now keeping American medicine in the front rank of intellectual and scientific achievement

The drift toward paternalism and pauperization is strong Benefident social workers have been working overtime to give us our Sheppard-Towner maternity bill, which will cost the taxpayers about $6,000,000 for five years Also a bill was introduced for the formation of a national board of health, with a seat in the cabinet providing for federation of all state, municipal, and county health officers, and placing them under a secretary of health at Washington It provides for a suitable central office for each health division and for regional hospitals and sanatoriums, to be supported jointly by the state and the federal government, so that adequate free facilities may be provided for all those suffering with infectious diseases, particularly tuberculosis as well as surgical diseases, in order that these diseases may be cured and eradicated Only $63,000 000 is needed to develop this idea

In New York State we have managed to escape the fetters of public health insurance for the time being, but we expect each year, that it will appear in the legislature under another name I shall not refer to the bills of this type that were introduced in the last Congress

CHARITABLE INSTITUTIONS

In the field of medicine, we find an increased number of public hospitals and charitable institutions, and there is an ever increasing attempt to build up, under governmental control and support, medical charities, in the nature of health centers, diagnostic clinics, bureaus of health insurance, compensation acts, and other like public activities for the purpose of caring for those who supposedly are unable to pay These medical charitable institutions however, are not confining their care to needy charitable cases, but, increasingly, by skilful advertising and other effective means, are bringing under their care those who are able to pay for medical treatment

The slogan of free health" has an alluring sound, but it is false in its concept The public needs protection, but primarily it needs education If the public were educated and knew what it is receiving, there would be no lodge practice or splitting of fees, and chiropractors and the other medical isms would disappear Faith in human nature leads many people to accept ideas from friends or take too seriously what they read It has always been an amazing anomaly that a man seeks and willingly pays for the highest degree of legal skill to protect his property, while he is willing to barter his life away to mediocrity

Prevention and education need the aid of the government, but the state should not compete with individual

* Chairman s address read before the Section on Urology at the Seventy Third Annual Session of the American Medical Association St. Louis May 1922

skill and superior knowledge and efficiency in the care of those who have money to pay and so should not be treated at public expense. The evil results are twofold. The medical profession will lose its motive and impetus to go forward, and, consequently, its standard will be lowered and its progress cease, and the patients who are treated free by the state will sacrifice their self-respect in their willingness to be pauperized.

The needy poor have always been cared for cheerfully by physicians, and it is reasonable to believe that this policy will not change. Many hospitals, and scientific laboratories have been established and the best facilities available have been installed to care for the sick when they are unable to pay. This class of patients is also desired by the college hospitals, where students are instructed by the best trained teachers. The college hospitals open their doors to the poor for this reason, and patients have the benefit of treatment by the most skilful physicians and surgeons in the community.

In the municipal or state-owned hospital, with its large financial backing, we find many positions for willing workers. Large buildings must be provided, with many beds, the more the merrier. Of course, if the management cannot keep these beds full, the number of employees must be cut down, so there is every inducement to care for as many patients as possible. Rivalry exists among these state-owned institutions to see which can hold the largest clinics. Naturally, the boards of trustees and the superintendents, if they have the money, will make every effort to develop large clinics, and the mere fact that a patient has plenty of money with which to compensate his family physician or a specialist for any treatment he may require will not interfere with his treatment free of charge if he is an "interesting case."

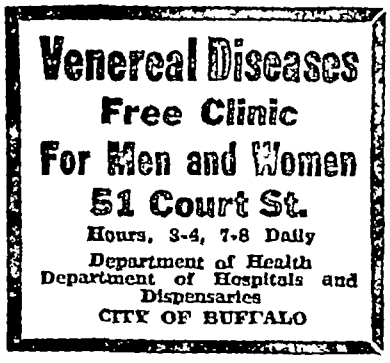

Fig. 1.—An appropriation of $2,500 a year was made by the city to carry this insertion in four of the daily papers.

HEALTH CENTERS

In Buffalo, the health center has been developed, and we have had ample opportunity to watch its growth. The department of hospitals and dispensaries is a well organized machine, 25 per cent of our physicians are serving with or without compensation, some on full time at from $1,500 to $3,000 a year.

In the urologic department, there has been a very rapid growth. By the expenditure of $2,500 a year for advertisements in the daily press, stating that patients are cared for free of charge, the treatments given were increased from 100, in 1916, to 24,949, in 1921. Urologists are employed at $760 a year for part time. One of our city urologists stated that he saw from fifty to seventy patients in a two-hour period three times a week. He accounts for the number of cases cared for by the excellent system. Gonorrheal patients irrigated themselves, the orderly massaged them and a nurse prepared the arsphenamin, so the urologist's only job was to insert the needle. There was no laboratory attached, and no smears or urine were examined. If the physicians wished these examinations made, the patients were sent to the city laboratory and reports made at a later date. Does any one think that these patients are *getting service*, even if it is free? There is no official dividing line between those whom they care for as free patients and those who are refused because of their ability to pay. An announcement has been made from time to time that any one making more than $20 a week will not be cared for. Therefore, those who came to the clinic in their automobiles never had an income of more than $20 a week.

With the necessity of seeing so many patients in such a short period, the dispensary physician must neglect his most important duty, that of advising the patient of the great danger of infecting others while he is still an active carrier of disease. He loses the personal touch with his patient which is the successful element in the treatment of disease. In private practice, the physician is not only a physician, but more often a friend also, and the relationship with his patient is a very personal one. Wholesale or commercial methods cannot succeed in medicine. The treatment of the sick is individualistic, and the state should not try to assume this function.

The private physician must compete with the government employee, the latter having offices, equipment and free drugs to aid him in procuring patients. He is content to accept the princely salary of from $75 to $150 a month. The private physician who cares for a venereal case is supposed to furnish his competitor, the government, the name and address of his patient.

This kind of interference would never be countenanced in the business world, but it must be remembered that the physician prides himself on not being a business man, therefore, he permits it.

Why not pay the laborer a living wage that would permit him to live and pay for his medical attendance, rather than ask the physician to make up the deficit in so-called charity hospitals and dispensaries? We want to give the needy poor better care than they have ever received before, but this cannot be done if we have to care for those who can afford to pay.

THE VENEREAL PROBLEM

Public health is the musical instrument easiest for the welfare worker to play and the softest chord is the venereal problem. They not only are able to stir the sympathies of the public, but also can arouse it to supporting the movement through fear of infection. The government has given considerable encouragement to this movement since the beginning of the war, together with semiprivate charities which have sprung up, claiming that they stand between the venereal clinic and the specialist with regard to the cost to patients.

The question whether or not free treatment and the ease with which it can be procured does not encourage the patient "to take a chance" rather than stamp out the disease, has yet to be answered.

The urologist, I believe, will, in a short time, be stripped of his venereal work so far as private practice is concerned. In the more technical field, the cystoscopic examination and diagnosis, together with surgery of the urinary tract, the encroachment will be less rapid, but nevertheless progressive.

RESULTS OF "FREE HEALTH"

To show how insidious is this virus of free health under the guise of medical charity, let me quote from

the announcement circulated in the health week campaign, by the council of the Medical Society of the County of Erie, the campaign headquarters being at the Buffalo City Hospital

Throughout the week members of the Medical Society of Erie County will be in attendance for diagnostic and advisory purposes, free of charge, regardless of financial standing of patient All reports will be mailed to physicians designated by applicants

This was a free campaign—free movies free exhibits and free medical examinations In the amusement column of the daily press, immediately above the announcement inserted by the Christian science church, appeared the advertisement presented in Figure 2

If we draw attention to the fact that physicians who are not on public payrolls will have difficulty in making a living should this so-called "free health" reach its logical outcome, the public may not be sympathetic until the awakening comes When, however, the physician's success becomes dependent on political preferment and the principle of medical socialism is substituted for the keen rivalry which now exists, and which calls for the best brains and the highest resource to achieve actual and deserved success, the patient will come to know that free health is at first a meaningless and then a dangerous term Health can be obtained and preserved through education and by the exercise of knowledge and skill It cannot be procured or maintained by the construction of palatial hospitals at public expense, and by the haphazard treatment of disease by physicians who are without personal interest in their patients, and whose reward is received from the public treasury and not in the consciousness of duty performed, with the incident recognition and success which such performance brings to the individual Socialized medicine can no more succeed than socialized industry has succeeded Its failure is as sure as its consequences are appalling There can be no such thing as free dispensaries and free clinics—they are bought and paid for by every member of the community They are expensive, as is everything conducted by the government, and the care given by the state to the sick has been and always will be inefficient Taxpayers have a right to protest against paying medical bills for those who are financially able to defray their own expenses It is making liars and cheats of numbers of people

Many have come to believe that this free service, for which they should be made to pay, should be extended to the matter of street car fares, and of gas and electric light

FIRST CHURCH OF CHRIST, SCIENTIST
IN BUFFALO NEW YORK ANNOUNCES A
FREE LECTURE
ON
CHRISTIAN SCIENCE
BY
MR JOHN J FLINN, C S OF EVANSTON ILLINOIS
Member of the Board of Lectureship of the Mother Church—The First Church of Christ Scientist in Boston Mass
ELMWOOD MUSIC HALL, Virginia and Elmwood Ave
ON FRIDAY EVENING, OCTOBER 21st, 1921
AT 8 15 O CLOCK — THE PUBLIC IS CORDIALLY INVITED

Fig 2—The upper advertisement which appeared in the Buffalo Express Oct 21 1921 was authorized by the council of the Erie County Medical Society To pay for this advertising campaign $1 600 was collected from milkmen instrument houses and druggists

It is not wise for a state to pauperize its people, nor is it fair to the medical profession to deprive it of its legitimate livelihood

The man who takes up the study of medicine in New York State must spend, after he leaves high school the equivalent of two years in college and four years of the hardest kind of study in a medical school, and at least one year's, or more often two years', internship in a hospital Before he can begin to earn his living he must spend seven or eight years in study and work

The physician has always been too busy looking after the needs of his patients to give much time to his own interest As we view the changed conditions in the last few years, unless he awakens to the drift of the tide there will soon be little inducement for a young man of real ability to enter the medical profession Even now, after he has finished his hospital internship, he finds that the cost of opening an office and waiting for a practice is appalling If he accepts a municipal or a state position, which gives him an income of $500 or $1,000 a year, it will help to tide him over a few years Habits are easily formed He receives a slight increase as years pass, but he loses the courage to break away and strike out for himself His ambition and incentive have been lost The young physician, ambitious to rise in his profession, and realizing that only by hard work and conscientious study can he accomplish this end, finds that, while he is improving himself, he incidentally is making himself a better public servant If his incentive and ambition are taken away by some government job, will he be any different from the clerks that we find now who have held the same position for years, and who if they lose their positions, are unable to support themselves?

Throwing aside all consideration of the medical profession, a very serious outlook confronts us Without realization of the outcome, a dependent class is being formed, a class which will next demand other benefits without pay or effort It is my belief that the time has come for action on the part of physicians who are proud of their profession We have been quiescent and complaisant, until the political doctors and doctor politicians have gained a foothold which will be hard to break They make an insidious plea for public support and a seductive argument to gain the good will of honest and fair-minded people They have patronage which they distribute judiciously among those whose help may be desired either within the medical profession or among outside political or other influential circles The medical profession cannot be free

and uncontrolled with these medical machines, powerful and active with their advocates and defenders, spread over a city or a state, with jobs to distribute and with power to destroy a private practice built up after years of struggle and faithful service

It will not do to scoff at the danger or minimize its importance. In its inception, it was harmless. In its spread, it has become a menace to medical men in their standing, ideals and progress. If we do not destroy socialism in medicine, it will destroy us.

The field of social welfare or social reform has developed to such an extent in recent years that it is now a recognized profession, remunerative and popular. The inauguration of a particular reform movement is usually followed by the formation of an organization with a membership more or less inactive but supplying funds to one or more secretaries to carry on active propaganda.

Let me add that I deplore this general and growing tendency to ask the government to do it rather than to do it ourselves. This inclination has been in direct ratio to the increase in our unassimilated aliens. They have always been directed or driven by some one who thought for them. It may have been for good or for bad. This class is easily influenced by propaganda to believe in the socialization of everything. We are being standardized, and sterilized and uplifted to the point of stupidity.

SOLUTION OF THE PROBLEM

The solution of this problem may be stated under three heads.

1. There should be a social service ably trained to make real and thorough investigations and competent to distinguish between the needy poor and those possessing the ability to pay.

2. There should be an awakening of the medical profession to the realization that it is equally responsible for this pauperization. There should be censorship of the services of the physician by some responsible body like the county medical society, as has been done in contract practice, so that patients able to pay should not be cared for gratuitously.

3. There should be education of the public to an understanding that if the standards of medicine are lowered through the loss of impetus and initiative in the young physician, the public will be the chief sufferer.

Ultimate Fate of Syphilitic Children.—A series of investigations, extending over twenty-five years, into the ultimate fate of children born of syphilitic parents—all in the better class of the population—gave the following results. There were 139 families with 569 children. The 139 women had 263 syphilitic infants born alive, 253 dead babies and fifty-three living, nonsyphilitic children. Of the 263 syphilitic children born alive, fifty-five died before the age of 4 years. Of the 208 individuals who were the subjects of prolonged observations, 25 per cent remained alive and without attacks, 14 per cent died within the first year. All the other children have shown symptoms of disease directly traceable to syphilis. Apart from manifestations on the skin and the mucous membranes, affections of the nervous system, together with moral insanity, were most frequent. According to the statistics of hospitals with their badly fed, unhealthy applicants, 70 per cent of all syphilitic babies die in their first year.—*Hochsinger Ultimate Fate of Patients with Hereditary Syphilis Among the Better Classes.*

DETECTION OF TYPHOID CARRIERS

REPORT OF FOUR OUTBREAKS*

J. N. GEHLEN, M.D.
Epidemiologist, Minnesota State Board of Health
MINNEAPOLIS

Formerly, field investigations of typhoid fever were seldom undertaken by the Minnesota State Board of Health, except in the presence of an outbreak of considerable proportions, usually traceable to a polluted water supply. Since 1911, epidemiologic field investigations have been made, as far as possible (1) when a physician or health officer requested investigation, (2) when data furnished by the attending physician or health officer, alone or when associated with previously collected data, have indicated some local source of infection, or (3) in the absence of pertinent data, whenever time and funds have permitted, many investigations being made while the investigators were in the field primarily for some other investigation, often weeks or even months after the occurrence of a single typhoid case.

Before going into the field, the epidemiologist looks up the history of typhoid fever in the locality to be investigated, as recorded in the files of the division of preventable diseases. Our files contain physicians' original case reports and all data previously obtained from physicians and health officers and collected by epidemiologists, together with original records of laboratory examinations of blood, feces and urine, including records of Widal examinations since 1896. In addition, the records of the division of sanitation, concerning city and village water supplies, sewerage systems and certain creameries and pasteurization plants are also accessible.

In the detection of typhoid carriers, carefully collected data, supplemented by the work of the laboratory, are necessary, as suggested below:

1. Detailed case data, with special reference to source of milk and cream, to places where patient partook of food during three weeks prior to illness and to changes in personnel in the home during the same period.

2. Widal specimens from all handlers of food and milk partaken of by patient or patients in the home and elsewhere, and from all members of patient's household.

3. Feces and urine specimens from all such food and milk handlers giving a history of typhoid or continued fever, and from those in whose blood the Widal reaction is present or atypical.

4. Feces and urine specimens from any person or persons to whom data point as a probable source of infection, even though Widal reaction and history of typhoid or probable typhoid fever are absent.

Since Jan. 1, 1913, the division of preventable diseases has identified and placed under supervision eighty-six carriers of typhoid (seventy-two) and paratyphoid (fourteen) bacilli. Four hundred and sixty cases and thirty deaths have been traced epidemiologically to these carriers, two of whom have meanwhile died.

Four outbreaks which illustrate different phases of the carrier problem have been selected for report at this time. In reality, two outbreaks each are reported under Outbreaks 3 and 4.

* From the Division of Preventable Diseases, Minnesota State Board of Health.

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

FIRST OUTBREAK

No cases of typhoid fever had been reported from D, a village of about 250 inhabitants, since 1913, when Dr W P Greene, then epidemiologist of the state board of health, traced thirteen cases, which had occurred during the three preceding years, to a woman who had had typhoid fever in 1910, and subsequently sold milk in the village March 4, 1921, a telegraphic request for assistance in an outbreak in children was the first information received by the division of preventable diseases that typhoid fever had reappeared in this village

Immediate investigation showed that eleven cases, eight in children, three in adults in four families, as shown in Table 1 had occurred between Dec 27, 1920, and March 2, 1921, the early cases having been diagnosed as influenza, pneumonia and "nervous breakdown" The three adult patients, and the two young children, aged 2 and 3 years, respectively, in the P family, had attended "Ladies' Aid" meetings, attended by numerous other women and children, where light refreshments, with coffee, and milk for the younger children, were served Except for these meetings and the usual frequent visits of close neighbors, there had been no visitors in these families, and the infected persons had not partaken of food away from home There was no history of previous typhoid fever in the

TABLE 1—DATA OBTAINED IN FIRST OUTBREAK

† Approximate

well members of the four families, and the Widal reaction was absent in blood specimens from all Three families used water from a spring, and one used cistern water

All four families took milk from the S dairy Mr S, aged 63, who had moved to the village in September, 1920, had had typhoid fever forty-three years previously His wife, aged 62, their four children, three of whom were away from home, and one granddaughter living with them, gave no history of previous typhoid A hired man developed typhoid fever in 1918 while working on their farm Mr S did the milking, and Mrs S handled the milk and milk utensils, which were never sterilized

At the time of the investigation, six families, two of which were free from infection, bought milk from the S dairy A seventh family used milk from this dairy from September till November, 1920, without becoming infected The Widal reaction was present in blood taken, March 6, 1921, from Mrs S, who gave no history of typhoid or other continued fever, and was absent in blood from her husband and the other members of the family living at home *B typhosus* was isolated from feces from Mrs S, March 16

It might be concluded that all cases in this outbreak were due directly to consumption of infected milk, since only one patient denied drinking or otherwise consuming raw milk or cream, at least occasionally

A study of the incidence of cases by onset, as presented in Table 1, along with that of the data obtained, suggests that all but the first two (in very young patients, both milk drinkers) may have been secondary cases, and that there may have been but one lot of polluted milk distributed In Case 5, in the H family, who denied consumption of raw milk or cream, the patient may have been infected through its use in cool coffee or tea or on desserts, or she may have been infected through direct contact with the patient in Case 2, who attended "Ladies' Aid" meetings while sick typhoid fever not having been suspected

Cases 9, 10 and 11 in the B family, and Cases 2, 3 and 4 in the P family, were intimately associated, the B family obtaining their drinking water (spring water) from the P family's kitchen It seems probable that Mrs B (Case 9) obtained infection from contact with the P family, and that the remaining cases in the P, H and B families were but indirectly due to infected milk The fact that there was no history of previous typhoid fever in the carrier's children and that no cases had occurred among her customers in D village for a period of three months, combined with the observation that she appeared to be a very neat housekeeper, rather favors this supposition

SECOND OUTBREAK

April 30, 1921, assistance was requested in a typhoid epidemic in a well settled farming community in northern Minnesota On investigation, May 1, it was found that fourteen men, all heads of families except one, had developed typhoid fever between April 10 and April 25 One secondary case developed later, and in five of the primary cases death ensued The cases were in three townships and were from 2 to 5 miles (3.2 to 8 kilometers) apart Each of the men had lived on his own farm for a number of years, having his own water and milk supply Well members of but one family gave a history of previous typhoid fever Five well members in the family of Case 8 gave a history of having had typhoid fever two years previously (In blood from three, the Widal reaction was positive, one set of discharges from each was examined, May 12, with negative results) *There was no history of previous typhoid fever in well members of the remaining thirteen families* All fourteen men, after careful questioning, denied having eaten away from home, except two who had had one and two meals, respectively, at different restaurants, in two villages

May 3, on inquiry as to farm sales, each recalled that he had attended a sale, April 1 About 100 persons were present at this sale The men were served a cold lunch, consisting of pork, hog's head cheese and cheese sandwiches, cookies, friedcakes and coffee The women and the auctioneer were served a hot meal without sandwiches

Four women prepared the food Three denied having had typhoid fever, and the Widal reaction was negative in the blood of two, but positive in the blood of the third woman Two sets of feces and urine specimens from this woman were examined with negative results Further specimens were unobtainable *Blood from the fourth woman, aged 65*, who had had typhoid fever thirty-three years previously, gave a positive Widal reaction, May 2, and *B typhosus* was found in nearly pure culture in a specimen of feces received June 7, after six days in transit Three of her seven children gave a history of typhoid fever This carrier had prepared the hog's head cheese in

her own home It is probable that this meat was infected by the carrier in removing it from the bones, a hand process, performed before the meat becomes cold A considerable mass of this warm chopped meat cooling slowly would act as an incubator for typhoid

TABLE 2—DATA OBTAINED IN SECOND OUTBREAK

Case	Sex	Age in Years	First Symptoms	Positive Widal Reaction	Comment
1	♂	58	April 8	May 9	
2	♂	29	April 10	April 29	Died May 4
3	♂	55	April 15	May 2	Died May 14

15	♀	11	May 29	June 11	Secondary to Case 12

bacilli, if present All who became sick had eaten meat sandwiches, although most of the men, very ill at the time of investigation, were unable to state whether head cheese or pork sandwiches had been consumed by them Of two brothers who received head cheese sandwiches, one threw the meat away, while the other ate the entire sandwich The former remained well, the latter developed typhoid, and died

The severity of this outbreak, attested by five deaths, which occurred among fourteen cases, may be accounted for by the ingestion, probably of a massive dose of typhoid bacilli, such as might be expected to be present in food handled under conditions favoring bacterial development The apparently long incubation period in the majority of these cases does not seem consistent with the incidence of cases in certain food outbreaks, and I believe that the actual dates of first symptoms in most of the cases were from seven to ten days earlier than the obtainable data indicated Robust and stolid types of men are liable to throw out of account slight symptoms of illness such as occur early in the course of typhoid fever At the time of investigation, the men were too ill to give much desired data

THIRD OUTBREAK

Between October 28 and November 19, 1920 five cases of typhoid fever, two in adults, three in children,

in four families, as shown in Table 3, developed in a small village in northern Minnesota The epidemiologic evidence pointed to the S restaurant as the source of infection, all patients having had several meals there during three weeks prior to first symptoms Mrs S, aged 54, who had had typhoid fever fifteen years previously, did all the cooking and handling of food, while her husband, aged 45, who had had typhoid thirteen years previously, occasionally helped in waiting on the table The Widal reaction was positive in blood from both, December 6 *B typhosus* was isolated from the urine of Mr S, December 20 One set of urine and feces specimens from Mrs S was examined, with negative results About this time the husband left the state, and his wife continued the restaurant business She refused to submit discharges for further examinations Again, during October and November, 1921, six cases of typhoid fever, three in adults, three in children, in six families, as shown in Table 3, developed in the village Again, the epidemiologic evidence pointed to this restaurant as the source of infection All except Patient 11, who nursed Patient 10, had partaken of food prepared by Mrs S, either at the restaurant or on some social occasion, within a period of three weeks prior to the first symptoms Since 1905, when Mrs S had typhoid fever, six cases had occurred among her relatives, her husband, two sons, a daughter, a daughter-in-law (Case 8) and one granddaughter (Case 2) all cases being directly traceable to her

16	♂	9	Sept 13 1921	Oct 1921	Secondary case

Under duress of immediate closure of her restaurant, Mrs S submitted specimens, and *B typhosus* was isolated from both urine and feces received, December 6 Mrs S was compelled to give up the restaurant business

FOURTH OUTBREAK

In Dakota County, two cases of typhoid fever in one family in a rural district, reported in January, 1921, were not known to have any relationship to a third case, which had been reported from an adjoining township in November, 1920 Data on these cases were given to Dr J A Carter, a graduate student at the University of Minnesota who had been assigned to the division of preventable diseases for practical field work, and, on investigation May 25 1921, he found that five undoubted cases of typhoid fever, involving three families, had occurred between September, 1920, and January, 1921 as shown in Table 4

In Case 1, not previously diagnosed, the patient had had the first symptoms of typhoid fever about three weeks after the arrival of a new housekeeper, Mrs S Case 2 was that of a boy who developed typhoid fever while working in the home of Patient 1 where he took one meal a day The patient in Case 3, unreported, son of Patient 1, lived at home and after becoming sick visited Patients 4 and 5, his brother and sister-in-law, respectively

Mrs S, aged 50, gave a history of prolonged illness with symptoms of typhoid fever during the early part of 1920 Though the Widal reaction was positive in her blood in May, 1921, four specimens each of feces and urine were examined with negative results

First knowledge of a second outbreak in two townships in the vicinity of the preceding one was received in October, 1921, when blood specimens from members of three families gave a positive Widal reaction in eight persons, six of whom had had first symptoms in August and September Investigation disclosed that eleven cases had occurred between August 1 and November 1, as shown in Table 4 The first, Case 6, developed about four weeks after Mrs S entered the home as housekeeper Patient 7, a child in the neighborhood, visited Mrs S daily, and consumed food prepared by her

The remaining nine cases, including six members of the family of Patient 7 and three persons in two neighboring families, were closely associated one with another, and were but indirectly traceable to Mrs S The Widal reaction was again positive in blood from Mrs S, and at this time *B typhosus* was isolated from urine

SUPERVISION OF CARRIERS AND NEED FOR THEIR COMPENSATION

The state board of health, directly through its own representatives or through the local health officer, gives such instructions to be followed by the carrier and members of his family as are necessary for their protection and that of other associates, and explains the state law, which forbids a carrier to engage in the handling of any part of the public's food supply which may be consumed without being cooked after handling

The local health officer is charged to keep the state board of health informed as to any change in the carrier's residence or occupation, and, as long as the carrier obeys directions, all publicity is avoided In one instance only has it been necessary to prosecute a carrier for illegally returning to a forbidden occupation

Three of the four carriers herein reported, one a dairy woman, another a restaurant keeper, and the third a practical nurse and housekeeper, were forced to abandon their chosen occupations, the nurse-housekeeper having no income aside from her earnings for the support of herself and one dependent Such restrictions of individual rights and liberty are necessary to protect the public against these innocent distributors of disease and death

Since 1915, the Minnesota State Board of Health has been entrusted by the legislature with the disbursement of a special fund for the support of a typhoid carrier who, after unauthorized newspaper publicity, was unable to obtain work Should not the state offer compensation to carriers who must give up their chosen occupation in order to protect its citizens?

ABSTRACT OF DISCUSSION

DR JAMES J DURRETT, Memphis Tenn Persons with chronic tuberculosis should not handle foods, and, if state compensation is given to one the other should participate, also carriers of other diseases might have a just claim The aggregate compensation thus distributed would be large, and, as we have *in most places trouble getting adequate funds for* recognized public health work we should not ask for money for this purpose just yet Formerly, when the death rate for typhoid was from 30 to 40, cases of typhoid were so numerous that small outbreaks *caused by carriers were masked entirely,* or made obscure and difficult to trace With the typhoid death rate below 10, cases are sufficiently few to make even a small, sudden increase in the number stand out clearly if not conspicuously I believe that this causes us to trace relatively more cases to carriers at this time than formerly Sanitation that purifies our water and safely disposes of excreta goes a long way toward protecting us against carriers of the typhoid bacillus who do not handle foods Those carriers who prepare food and handle raw milk constitute a special problem and when detected they should be compelled to abandon this type of work, and they should be taught personal hygiene

DR JOSEPH N GEHLEN, Minneapolis With higher standards of water purification and with partial supervision of milk supplies in the larger cities and villages of Minnesota during the last few years, most of our outbreaks have been caused by carriers, although we have not always been able to trace the source The question is what to do with carriers after we find them We keep food and milk handlers out of business, and it does not seem fair to have their usual method of livelihood taken away from them without some form of compensation

---

NUTRITION IN SCHOOLCHILDREN*

TALIAFERRO CLARK, M D
Surgeon U S Public Health Service
WASHINGTON, D C

It is not the purpose of this paper to discuss nutrition from the standpoint of calory requirement, relative protein nutritive value, vitamin content or metabolic processes Our inquiry is directed more particularly to certain phases of nutrition work now being widely attempted in the schools, and which may affect, for better or for worse, 20 per cent of the total population, representing the approximate school enrolment of a given community

For untold generations, men and women have been born, "had their being," and died at a ripe old age, without thought of the state of nutrition or the character of the food ingested other than that inspired by a catholic appetite But, within the last few years, all has changed, and the popular conception of malnutrition is—shall I say?—so inaccurate that the veriest tyro in public health work, after placing a child on a scale and noting comparative results, gravely announces the percentage of malnutrition in a given population group, and, in addition, prescribes the remedy

Nutrition, or rather its opposite, malnutrition, bids fair to become a fad with large numbers of people of limited training and experience in health matters, although such men as McCollum, Mendel, Osborne, Hess and Unger in this country and many investigators in other lands as yet but "see through a glass darkly," despite the great advances made by them in the knowledge of metabolic processes and relative food values

REPORTED PREVALENCE OF MALNUTRITION IN SCHOOLCHILDREN

The percentage of "malnutrition" (underweight) in schoolchildren reported by different observers varies widely, not only for children residing in the same locality, but also for those residing in urban as contrasted with rural communities

According to Emerson,[1] approximately one third of the schoolchildren of the country suffer from malnutrition In New York City, there seems to have been

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Emerson W R P Nutrition and Growth in Children 1922

a progressive decline in the percentage of malnutrition observed in schoolchildren, as shown in Table 1.[2]

The data first reported for New York City are based largely on estimates of nutrition according to the Dunfermline scale. Later, however, the relationship of weight to height was considered also in estimating nutrition status.

Walter S. Cornell,[3] director of medical inspection of schools, Philadelphia, reports that from 5.6 per cent to 22.3 per cent of 12,817 schoolchildren recruited

TABLE 1.—MALNUTRITION IN NEW YORK SCHOOLCHILDREN

Year	Number Examined	Percentage of Undernourishment
1917	171,691	21.6
1918	184,374	19.0
1919	248,064	20.0
1920	241,064	17.7

from the poorer districts of that city are 10 per cent or more underweight, as shown in Table 2.

Of 26,318 schoolchildren examined in Cleveland, 1921-1922, L. W. Childs, director of health education for the board of education of that city, reports that 3,914, or 14.8 per cent., were 10 per cent or more underweight, according to the Emerson scale.[4]

During the present school year, 17.9 per cent of the schoolchildren of Detroit were found to be 15 per cent or more underweight.[5]

In a survey made by the Elizabeth McCormick Memorial Fund,[6] Chicago, in 1920, 57.7 per cent of the children attending a school situated in a "comfortable semiurban neighborhood" were reported as malnourished, and but 16.2 per cent of those attending a school of the stockyard district were so classified. According to those reporting, this seems to indicate that so far as these children are concerned, underweight is not altogther a question of either the quantity or the quality of the food supplied.

Reports of underweight observed in rural schoolchildren vary even more widely than do those for the cities. Service officers engaged in field investigations in child hygiene have, for a number of years, directed comparative studies of underweight in the schoolchildren of several states, as a part of these investigations. Following are some of the reported observations.

In Missouri, 1920-1921, of 9,214 schoolchildren examined in twenty-two towns, 38.3 per cent of them were 7 per cent or more underweight, as compared with 34.5 per cent of the 1,698 children examined in the schools of three rural communities.

In five Mississippi counties, of 11,270 white schoolchildren and 5,840 negro schoolchildren weighed and measured in 1920 and 1921, 5,436, or 48.2 per cent., of the former, and 3,111, or 53.2 per cent., of the latter were 7 per cent or more underweight, respectively. However, these percentages may not accurately represent the prevalence of underweight among the schoolchildren for the state at large because the counties selected for study are notably affected by hookworm and malaria.

Of 1,841 children attending school in a favorably located and prosperous county in Florida, who were weighed and measured in 1921 and 1922, 591, or 32.1 per cent., were 7 per cent or more underweight.

WHAT IS MALNUTRITION?

In view of the varying and alarming percentages of malnutrition reported by different observers, one might well pause to inquire whether malnutrition is a distinct pathologic entity or merely a symptom. If the former, is the very great reported prevalence due to a newfound ability to recognize a disorder that has been of common occurrence for years past, or to change in the quantity, quality, selection and preparation of foods in common use? On the other hand, may not the widely varying percentages be due, in very large part to the use of inexact standards for measuring nutrition, and, in instances, to defective and inaccurate apparatus?

I am not prepared to accept the popular conception of malnutrition as a distinct pathologic entity, and I believe that it is a symptom due to manifold causes operating either singly or in combination. This point of view is very succinctly set forth in a statement by Sir George Newman, quoted by Frank A. Manny, special investigator of the New York City Bureau of Welfare of School Children:

> In endeavoring to estimate a child's nutrition or its opposite (viz., malnutrition), we must think not only of bulk and weight of body but of ratio of status to weight, of the general balance and "substance" of the body and of its carriage and *bearing, of the firmness of the tissues, of the presence of* subcutaneous fat, of the condition and process of the development of the muscular system, of the nervous and muscular system as expressed in listlessness or alertness in apathy or keenness, of the condition of the various systems of the body and speaking generally, of the relative balance and coordination of the functions of digestion, absorption and assimilation of food, as well as of the excretion of waste products. It is obvious that these are data which are likely

to lead to a much more reliable opinion than the consideration of any one factor or ratio however, expeditiously obtained or convenient in form or practice and these data will demand a wider as well as a more careful and accurate observation of the whole physique of the child. Nor can an ultimate opinion always be formed at one inspection at any given moment. For nutrition, like its reverse, malnutrition is a process and not an event.

Many factors are conducive to underweight. Of these may be mentioned causes relating to the diet, to personal and general hygiene, to lack of exercise or to overexercise, to defect and disease, to possible inherited

tendencies and to environment, all modified in varying degree by the economic and educational status of individual parents and the disciplinary control exercised by them over their offspring Furthermore, is weight alone a true measure of nutrition? Is it not possible to fatten a child, as, for example, an infant fed for a prolonged period on condensed milk, and yet fail to promote proper skeleton growth or increase in vital stamina? Is it not possible, by regulating the diet and daily routine, to cause a child to take on fat, even in the presence of a grave pathologic lesion, and this without removing the cause? Underweight or malnutrition, if you please, is a distinct medical problem that must be combated by medical measures

STANDARDS OF NUTRITION

A number of different standards of physical development have been advanced for use as a measure of the state of nutrition Practically all of them estimate nutrition in terms of weight The standards most generally used in this country are two, one devised by W R P Emerson of Boston and the other by Thomas D Wood of Teachers' College, New York Both of these standards are based on weight in relation to the standing height according to sex, with the difference that Wood's tables consider the height and weight in relation to age The more recent tables promulgated by Emerson also take into consideration the age factor The chief objections to these tables are

1 The standing height, which is subject to wide individual variation, is used

2 They represent the average measurements of large numbers of children, it is true, but include children who are undernourished, or who are suffering from physical disability in varying degree, no doubt, including the measurements of a number with spinal curvature and other deformities which materially affect stature

3 A percentage deviation from the average is arbitrarily adopted to represent undernourishment, ranging from 7 per cent, according to Emerson's standards, to 10 per cent, according to those advocated by L Emmett Holt

4 They fail to take into consideration hereditary factors which influence stature, on the assumption that the height-weight index applies to all races This may be true, but has not yet been conclusively proved

5 They are confessedly approximations

BALDWIN'S TABLES

For a number of years, the child research station of the University of Iowa has been making a series of observations of special groups of children, under the direction of Dr Bird T Baldwin[7] These children have been examined from year to year, and carefully measured and weighed, and the results have been embodied in tables that represent probably the most scientific study of this problem which has yet been made in this country

Objections to Baldwin's tables are based on the ground that these measurements represent a selected group of children who, because of the very fact of their being weighed and measured periodically, are subjected to special bettering influences, a group which probably becomes more select through the falling out of the unfit from year to year Furthermore, although these data were collected in widely separated communities, the number of children included are relatively few as compared with the total for the country as a whole Considering the reported sources of the data used, the measurements of certain age groups may not be representative because based on a larger or smaller amount of data from single localities, with possible complicating race factors

FOREIGN STANDARDS

Considerable interest in two foreign standards of nutrition has been manifested in this country within the last two years Pirquet's pelidisi index, and Dreyer's assessment of physical fitness

Pirquet's Index of Nutrition.—In contradistinction to the conception that energy exchange stands in definite relation to skin area, Pirquet of Vienna conceived the idea that the intestinal area, representing the surface which governs the amount of food absorbed, affords the proper basis for the determination of normal food requirements In calculating the intestinal area he used the observation made by Henning, in 1821, that the length of the intestine in centimeters is ten times the sitting height in centimeters, and, "as deduced from various observations on intestinal volume" that the width of the intestine is equal to one tenth of the sitting height, both measured in centimeters On this basis, the area of the intestine is expressed as $10\ S_1 \times \frac{S_1}{10} = S_1^2$

However, the food requirements of individuals differ widely, owing to many factors In this connection Pirquet worked out an index of nutrition based on the weight-sitting height ratio, the so-called pelidisi, namely ten times the weight in grams divided by the cube of the sitting height in centimeters A well nourished child, according to Pirquet, will register 100 per cent In the practical application of his system to the feeding of many thousand Austrian children by the American Relief Administration, all the children that registered 94 per cent or less were considered undernourished

Furthermore, Pirquet does not rely on the weight-sitting height ratio alone in estimating the state of nutrition and the food requirements of individual children, but classifies them under four headings, according to the results of physical examination, namely, sanguis (blood), crassitudo (fat), turgor (water-contour), and muscularis (muscle)

Using the first consonants in each of these four words as a skeleton, namely, s, cr, t and m, and inserting after each of these symbols the proper vowel, "a," representing normal, "e" and "i," moderately and greatly increased, and "o" and "u," moderately and greatly decreased respectively Pirquet coined the word "sacratama" to indicate a child in normal nutrition By substituting other vowels to form, for example, the word "socrotemo," this would indicate a slightly anemic moderately thin, fairly rounded out child of moderate muscular development

Pirquet's system is probably more useful in connection with feeding large groups of children Serious objections have been offered to the application of the system to individual children, because it is based largely on theoretical premises

In a comparison of "pelidisi" with percentages by the Wood tables in a series of 984 Los Angeles schoolchildren, Faber[8] found that approximately one half o

7 Baldwin B T Physical Growth of School Children Extension Div Bull No 59 University of Iowa Dec 1 1919

8 Faber H K The Pirquet System of Nutrition and Its Applicability to American Conditions J A M A 77 1837 (Dec 3) 1921

them would be graded as undernourished by the Pirquet scale, in comparison with one fifth and one ninth as 7 per cent and 10 per cent undernourished, respectively, by Wood's tables

Representing the results of his study of these two scales by frequency graphs, Faber was able to show that, of the entire series of 984 cases, only 24 2 per cent showed comparable indices of nutrition Commenting on these findings, Faber declares that "from a statistical study of this sort, it is impossible to decide which method is at fault"

Dreyer's Assessment of Physical Fitness—John Hutchinson, as far back as 1846, observed that patients suffering from pulmonary tuberculosis showed a lessened vital capacity Inspired by Hutchinson's observation and stimulated by his experience during the World War, when vital capacity was made an important consideration in the selection of candidates for the British flying service, Georges Dreyer,[9] professor of pathology, Oxford University, made a series of intensive studies of carefully selected groups of persons, varying widely in age and physical development, and apparently he has been able to establish a definite relationship between vital capacity and certain body measurements, and to express the vital capacity as a function of these measurements

According to Dreyer, when the weight in grams raised to the two-third power (or more accurately 0 72) is divided by the vital capacity, a normal constant for persons of the same class (occupation, mode of living, etc) will be obtained, irrespective of age, weight or height Some of his other formulas are as follows, V C being equal to vital capacity in cubic centimeters, N equal to 2, K equal to a constant, L equal to sitting height in centimeters, and Ch equal to chest circumference in centimeters

$$\frac{L^2}{V\ C} = K^2$$

$$\frac{Ch^2}{V\ C} = K^2$$

$$\frac{L \times Ch}{V\ C} = K^2$$

By the use of these formulas, Dreyer has prepared a series of tables, for both males and females, of weight in relation to sitting height, chest circumference and vital capacity

Weight is classified as (1) possibly abnormal when it is found to be 5 per cent above or below the calculated normal, (2) probably abnormal when it differs from the normal by 10 per cent, and (3) certainly abnormal when the deviation is as much as 15 per cent from the normal calculated for a given sitting height, chest circumference or vital capacity

Different persons, all apparently in good health, exhibit great differences in vital capacity, depending on the occupation and mode of life This difference in normal persons, according to Dreyer, has nothing to do with fundamental bodily deficiencies, because it can be remedied by exercise and other measures

I have long considered the sitting height a more reliable measurement than the standing height for determining physical standards, and I believe that Dreyer's methods and results should be carefully studied for comparison with the standards now in more or less general use in this country

9 Dreyer Georges and Ranson G T The Assessment of Physical Fitness London, Cassell and Company *Limited 1920*

THE DUNFERMLINE NUTRITION SCALE

The Dunfermline scale introduced by Dr Alister MacKenzie of the Carnegie Dunfermline Trust, at Dunfermline, Scotland, distinguishes four nutritional groups on inspections

1 "Excellent" means the nutrition of a healthy child of good social standing

2 Children whose nutrition falls just short of this standard are classified as "good"

3 Children "requiring supervision" are on the borderland of serious impairment

4 Children "requiring medical treatment" are those whose nutrition is seriously impaired

The use of this scale presupposes medical training and experience Following are some of the comparative results of the application of this scale by medical officers of the U S Public Health Service, modified as to terminology, to 9,973 schoolchildren, largely of Anglo-Saxon stock, residing in Delaware, Maryland, New York, South Carolina and Virginia

TABLE 3—PERCENTAGES OF 9,973 CHILDREN CLASSED AS OF FAIR OR OF POOR NUTRITION

Age	Both Sexes	Boys	Girls
6	17 6	18 6	16 6
7	19 9	20 1	19 6
8	20 7	22 1	19 2
9	18 8	18 0	19 6
10	18 0	17 1	19 1
11	18 9	19 0	18 9
12	15 1	16 4	13 9
13	12 8	13 1	12 5
14	12 4	11 7	13 0
15	9 0	12 3	5.7
16	7 1	8 4	6.2

1 The percentage of defective nutrition in children classified according to clinical evidence other than weight was highest at 8 years of age, decreasing with age, as shown in Table 3

2 From the fact that the mean measurements of the children classified as of fair or of poor nutrition were constantly less than those classified as of good or of excellent nutrition, the children classified as malnourished from clinical evidence other than height and weight, are shorter and lighter, and have a smaller weight-height index

3 Differences in height are much less significant in judging nutrition than in judging differences in weight

4 In comparing the percentage distribution of the two groups classified as of good or of poor nutrition, according to clinical evidence other than height and weight, it is found that while on the average the children in the latter group weigh less than those in the former, some of the children in the poor group weigh more than some of the children in the good group This is additional evidence that weight measurements alone are not sufficient for determining nutrition, but that these must be supplemented by medical examinations

PROPOSED STUDY OF PHYSICAL STANDARDS BY U S PUBLIC HEALTH SERVICE

The Public Health Service is now making some careful studies of the physical development of schoolchildren in cooperation with the divisions of child hygiene of several state boards of health It is purposed to extend these studies and to secure the cooperation of other state and municipal boards of health, in order that special measurements may be obtained of selected classes of children residing in both urban and rural communities, in sections of the country more or

less homogeneous in population and subjected to practically the same climatic conditions

The measurements will be made in the case of certain racial groups, namely, children who may be considered of native American stock, native born children of foreign born parents, according to race stock, and of foreign born children, according to race stock They will be made in identically the same manner with instruments that have been standardized, and recorded on a special form The special measurements will be used in calculating standards for comparison with those already in use, both in this country and elsewhere, and as the basis of standards applicable, if not to the country as a whole, at least to the different sections of the country from which the data were obtained In fact it is a question in my mind whether we can hope to adopt a standard which will be applicable to the country as a whole owing to the effect of the wide geographic distribution of our population whose various elements are thus subjected to varied climatic influences and, therefore, different food supplies, and also because of the impress which necessarily must have been made on physical development by the tremendous alien immigration to which this country has been subjected in the last twenty or more years

RELATION OF PHYSICAL DEFECTS TO UNDERWEIGHT

During the present scholastic year, one or more physical defects were noted in 74 9 per cent of 8,887 schoolchildren in Detroit who were 15 per cent or more underweight No outstanding defect was observed in 25 1 per cent of them [9]

The reported percentages of defects found in greatest frequency were enlarged or infected tonsils, 50 8 per cent , defective teeth, 22 7 per cent , faulty vision, 9 3 per cent , mouth breathing, 9 2 per cent

A comparison of gain in weight by children without nasopharyngeal obstruction and those recommended for operation in a study made by the bureau of educational experiments, New York City [10] showed that 68 87 per cent of thirty-two children without this defect made gains in excess of the normal, as compared with 55 1 per cent of those without correction In comparing the relative gain, however, only 6 1 per cent of those having defects showed over 100 per cent gain in excess of the normal, as compared with 31 3 per cent for those without defects

In April, 1920, a study of 200 underweight Baltimore schoolchildren from 7 to 14 years of age was made by officers of the U S Public Health Service to determine the effect of the removal of physical defects on the rate of growth as represented by height and weight [11] These children were exempted from nutrition instruction and from any special hygiene other than the correction of their physical defects The higher percentage of monthly increase in weight noted may be largely, if not wholly, attributed to the correction of the physical defect

It was found that the percentage monthly increase in the weight of boys and girls from 7 to 10 years of age was 0 47 per cent and 0 27 per cent , respectively, before the operation for diseased tonsils and adenoids, as compared with 1 80 per cent and 2 05 per cent after the operation In the case of children from 11 to 14 years of age, the percentage of increase was 0 47 per cent and 0 84 per cent , respectively, before the operation and 2 04 per cent and 1 99 per cent after the operation It is safe to assume that underweight in the case of these children was due largely to toxic absorption rather than to improper feeding Expected percentage increase per month in weight computed from tables of average weights is presented in Table 4

TABLE 4—EXPECTED PERCENTAGE INCREASE PER MONTH IN WEIGHT COMPUTED FROM TABLES OF AVERAGE WEIGHTS

Tables	Age	Boys	Girls
Emerson	7 to 10 years	0 78	0 77
U S P H S	7 to 10 years	0 72	0 79
Emerson	11 to 14 year	0 83	0 97
U S P H S	11 to 14 years	0 82	0 97

TENDENCY OF STAPLE CROPS TO MODIFY NUTRITION

It is doubtful that more than a few children in this country are undernourished because of too little food

According to McCollum,[12] "low vitality, low resistance and inefficiency, and a tendency to cumulative fatigue' result from adherence to a faulty diet, and a diet of cereals, tubers and muscle-tissue meats is inadequate Furthermore, the cereal grains, which are incomplete foods, are coming into more extended use because of the tendency of farmers, owing to ease of production and probable relative low cost of production to plant larger and larger acreage to these grains which are so materially reduced in nutritive value by faulty milling It is necessary to supplement the bread meat and potato diet with milk and green leafy vegetables in order to supply mineral and accessory food factor deficiencies In actual practice, however, the application of this thoroughly sound knowledge will be followed by failure unless at the same time other causes of malnutrition are looked for, considered and controlled Of what avail is it to advise the underweight schoolchild to use milk when there is no milk? or to prescribe the leafy vegetables when the cereal grains and cotton form the staple crops in large areas of our country, even to the exclusion of products of the garden plot? Here nutrition becomes a matter of general education and of change in community custom and habit, involving time, and of state and federal guidance It is not merely a question of weighing and measuring

NUTRITION WORK IN RELATION TO REGULAR SCHOOL ROUTINE

So serious are the demands made on the time of both pupils and teachers by those engaged in or wishing to engage in sundry forms of welfare work, and by others with newly devised schemes for the general uplift which they wish first to try out in the schools, that any great extension of such activities, it seems, will leave but little time for instruction in the three R's It is for this reason, all basically related forms of school health work should be united and harmoniously fitted to the general plan of health instruction and health supervision, utilizing the combined wisdom of both the educational and health authorities for such purpose

Courses in health should be prescribed and given weight in the school curriculum corresponding to major

[10] Health Education and the Nutrition Class a report of the Bureau of Educational Experiments New York p 57

10 Health Education and the Nutrition Class a report of the Bureau of Educational Experiments New York p 57

11 Correcting Physical Defects in School Children Pub Health Rep 37 No 15 (April 21) 1922

12 McCollum E V Simmonds N and Parsons H T Supplementary Protein Values in Foods J Biol Chem 47 111 139 173 207 235 (Jun) 1921

subjects Such instruction naturally should be adapted to the intellectual capacity of the different age groups As regards nutrition, teaching in the early grades should be concerned more with the importance of milk, vegetables, fruits, cereals and the like, in the diet, from the standpoint that they help to make the child grow up to be strong The teaching of the principles of nutrition and nutritive values should be reserved for the older grades

Instruction in nutrition should not be reserved for and given only to a special group of children, either underweight or otherwise, but should include all children attending school, else we shall not find succeeding generations attaining the best possible physical development Such instruction is necessary for the guidance of the potential parents of future generations, and to overcome the ignorance now so commonly observed concerning these principles and values

Special nutrition classes for malnourished children are unnecessary in a well conducted school system providing proper health supervision Children judged to be undernourished, by whatever standard, are candidates for open air classes and open air schools, where everything possible may be done to restore them to normal, including supplementary feeding, examination for and correction of physical defects, special instruction and graduated exercises, rest periods and a follow-up system reaching into the homes

Weighing and measuring should be considered a necessary measure in every physical examination, and, in the case of children who fail to gain or lose weight steadily, the causes should be investigated and corrected

The character of the school lunch should receive careful attention, especially in rural schools, where many children frequently come long distances after a hurried breakfast, bringing a hastily prepared, poorly selected lunch, or none at all, and remain all day Aside from the question of the effect on health, an underfed child is no more fit for mental effort than is the laborer for physical tasks

I do not wish to convey the impression that I can find no good in the nutrition work now being done by so many earnest, and, at times, inexperienced workers, because, for the most part, the measures recommended by them, if carried out, will be helpful in overcoming defective nutrition, no matter what may be the underlying cause Furthermore, their persistent activities have served a very useful purpose in stimulating thought and action by those in positions of responsibility and qualified by training and experience to advise in such matters Among the objections to unsupervised and indiscriminate nutrition work may be mentioned

1 The tendency of the popular fancy to make a fad of a serious problem

2 The danger that the enthusiasm of untrained workers will cause them to lose sight of the fact that nutrition and its opposite are medical problems requiring the best obtainable medical advice in individual cases

3 The creation of a false sense of security in the mind of the parents of underweight children, by the temporary improvement following the application of well known principles of hygiene to ailing children, with potential disastrous after-effects, unless the treatment provided is based on medical advice

CONCLUSION

I wish to emphasize that, in calling attention to the need of proper supervision of lay and nursing workers in nutrition, I must also call attention to the apathetic, and in many instances, indifferent attitude of the medical profession to the danger signals that have been so prominently brought to the front by the lay workers, and urge the importance of physicians' displaying more active interest in nutritional problems and giving more hearty support and cooperation in solving them

ABSTRACT OF DISCUSSION

DR BORDEN S VEEDER, St Louis Every pediatrician has reached the point of view that malnutrition is an individual problem and not a group problem There are a number of causes for malnutrition, among which may be mentioned physical defects economic conditions, the environment of the child, and health habits If you take a group of malnourished children, you will find one who has cardiac disease, a second with hyperthyroidism, a third who does not have the proper amount of sleep, a fourth who does not get the proper amount or, perhaps, the proper kind of food and so on In other words in nearly every case of malnutrition, there is some one or more causes, and consequently malnutrition cannot be looked on or treated as a disease, but must be regarded as a symptom which may be produced by a number of causes In order to understand an individual case properly, it must be studied from all sides, not only the physical but the environmental The physician who sits in his office and tries to treat malnutrition by physial examination of the child alone, without entering into the life and habits and environment of the child, will not get very far, nor will the nutritional worker who tries to treat malnutrition by diet without understanding the physical background If one tries to reach the malnourished children in groups, each group must be small so that the individual child can be studied I think that the study of malnutrition has led us all to the conclusion that one of the chief factors is overfatigue The child who does not get enough rest whether it is from lack of sleep, or from overexcitement, overwork or something that has to do with its habits, is not a healthy child and is usually malnourished, whether or not there are any physical defects present The unfortunate thing about the subject of malnutrition is that it has been made a fad, and a good deal of the malnutrition which is said to exist in many of our schools, as a result of weighing children, is actually nonexistent We find that malnutrition is more common in the lower grades than in the higher grades, although no efforts have been made at all to correct conditions If one leaves a large percentage of the malnourished children alone for a year or so, a very large number of them will seemingly get well no matter how one treats them Although the amount of attention and notoriety that has centered about undernourished children and malnutrition in the last few years has probably done a lot of good by calling attention to the physical condition of the child, still it is my feeling and I know, the feeling of many pediatricians, that a grave mistake has been made by a great many persons in regarding it as a group problem rather than a problem of the individual

DR JOHN DILI ROBERTSON Chicago Lafcadio Hearn said years ago 'God never repeats His work" An individual once removed will never return or be duplicated through the eternity of eternities In other words, no two individuals, even in the same family, are exactly alike This being the case it is difficult to make standards for the purpose of determination of so called malnutrition The condition can not be determined by the same standards In other words, we have no proper standard for easy determination of the condition of nutrition By use of the yard stick the age and the scale, thousands of children throughout America have been labeled as suffering from malnutrition without the history of their forebears being taken into consideration In the majority of instances, a child follows the hereditary course of one or more of his ancestors There is undoubtedly much malnutrition This can be determined only by careful physical examination by an expert physician who is qualified to check up not only his digestive, respiratory and nervous systems but every other system of his body This cannot be done in the school, for it is necessary to check up on the blood and urine, and to make other laboratory tests To say that a child is underweight and therefore must be fattened up, with-

out a thorough examination, is to grope in the dark Would it not be better to investigate heart, lungs, kidney capacity, etc before advising Willie to put on a few more pounds, which will require more blood vessels perhaps, than heart can accommodate, perhaps more tissue than the excretory organs can care for? The so-called nutrition clinics in our public schools, during the last three or four years, have run the course of all fads, and, like every other fad, will disappear and be replaced by a sane program This program cannot be carried out by nurses or by physicians not specially trained In other words the grocery clerk system of weighing, aging and measuring must be abandoned for one conducted by trained medical men

Dr Allen J Hruby, Chicago The fad of the nutritional clinic has run its course in the public schools of Chicago, under the supervision of teachers and club women Our work in the Municipal Tuberculosis Sanitarium has shown us that some very careful work is necessary before we can adopt any standard Dr Grace S Wightman, with a committee of dispensary physicians, was selected to take charge of a group of schools, to see whether they could adopt a standard for nutrition by a careful anthropologic study of the children The final conclusion is that a careful clinical history and physical examination must be made together with a study of the economic and sociological conditions, also a complete laboratory examination and an investigation of the condition of the internal secretions, before any conclusions can be arrived at We have concluded in Chicago that all these points must be taken into consideration before we can make a diagnosis of malnutrition

Dr W L Holt Knoxville Tenn I have been much interested in this problem of malnutrition in the South One of the things I noticed was the shortage of milk I take 6 quarts of milk in my own family so that as a health officer I practice what I preach I found a great deal of malnutrition in Knoxville In one school in the poor district not less than 28 per cent of all children were 10 per cent or more underweight, and we found a great difference between the boys and the girls 18 per cent of the boys and 35 per cent of the girls being 10 per cent or more underweight That is one thing I am particularly interested in and I should like to ask Dr Clark or any one else what his explanation is regarding this difference in percentage between boys and girls I also want to ask Dr Clark what a reasonable amount of milk is for the average schoolchild I believe that a quart is reasonable, but some men think a pint and a half

Dr Isaac D Rawlings, Springfield Ill I have been much interested in this paper because in Illinois we have felt that when weighing and measuring of schoolchildren is done without any physical examination this procedure is more or less of a fad We have been really concerned over the possibility of doing harm by labeling children as sufferers from malnutrition, and giving them milk that is not made safe by pasteurization In 1911 we passed a law that no municipality could require tuberculin testing of the cattle supplying milk to the municipality, so we have no testing of tuberculous cattle except by virtue of the accredited herd act I have found by consulting the newspaper clippings that the various clubs throughout Illinois have organized a plan of weighing and measuring children and have then fed these children I understand that the milk is often not pasteurized and I am afraid that it is not safe and that the children are really in danger from it. As to their physical condition and the need of food, it seems to me that this feeding is ill advised unless measures are taken to see that pasteurized milk is supplied when it is necessary to feed these children If it cannot be obtained, commercially pasteurized, some method should be instituted whereby it is pasteurized at home or at school before being given to the children

Dr Florence Meredith, Philadelphia In Philadelphia, and perhaps everywhere, there is a tendency to overemphasize what may be done by merely weighing and measuring children and increasing the caloric intake Malnutrition is a medical diagnosis often most difficult for the physician to make Weight offers only one diagnostic point increasing the number of calories is only one remedial measure The technic of the lay nutrition worker, valuable as it is, should be supplementary to thorough medical work wherever possible Ideally, each case of malnutrition should be handled individually as to diagnosis and treatment The nutrition class has met a certain need, because of the large number of children to be dealt with But it is certainly not possible to do as good work with a group as with individuals The sooner we are able to treat malnutrition as a medical problem and an individual problem, the better All honor to those who have been successful with the class method, however For a long time yet it will be the only possible method of dealing with a great deal of the malnutrition

Dr James Stewart St Louis I cannot say that I regard the question of nutrition and the selection of children supposedly suffering from malnutrition as being entirely a fad In St Louis we have established a very efficient and conservative system We felt that the question of nutrition should not be in the hands of the teachers or school principals We believe that weighing or measuring of children should be entirely in the hands of the school physician or school nurse We were fortunate in having a demonstration carried on by the Pubic Health Service in St Louis a few years ago, and through that experiment we gained information that was so satisfactory that the board of education asked us to continue the work The school hygiene division asked that a college course in nutrition of two credits, be given to all school nurses This has been completed within the last few weeks We selected a group of children in the open-air schools, who were put on a regular routine of diet and health habits Those who were found to be physically impaired had their defects corrected and the home surroundings improved by conferences with the father or mother or the one responsible for the child With that cooperation, we believe that the work has been well done It is our object that all school systems throughout the land will leave that work in the hands of the school physician or the school nurse, because, with the experience of the physician and the nurse, these children will be brought up to the proper standard, and because of the child's improved physical condition he will be able to go through school and graduate with less effort possibly on the part of the teacher and of himself That is an economic advantage that should be recognized In our open air schools, the number of undernourished children and of cases of contagious diseases has been very low as compared with the regular elementary schools That shows what these health habits and the building up of the child suffering from malnutrition accomplish when children are brought up to a special standard and their resistance has been increased to such an extent that contagious disease in these schools is practically nil

Dr Taliaferro Clark Washington, D C The object of my paper is not merely to call attention to nutrition work by untrained agents but to sound a warning that they must not let their enthusiasm run away with them to the extent that they lose sight of the fact that malnutrition is a health problem On the other hand I must also sound a warning to those in authority and to practicing physicians that unless they wake up and take notice of underweight as a danger signal the lay workers are going to continue this work unsupervised and with potential unhappy results In regard to standard of physical development I believe that it will be rather difficult to accept or adopt a standard that would be applicable to every child in every part of the country Many factor must be considered in the preparation of such a standard The Public Health Service at present is beginning a nation-wide study of the physical development of children that takes into consideration numerous factors bearing directly on this problem One of the first steps considered was the standardization of the apparatus to be employed so that measurements made by different persons in widely separated communities would be exactly comparable Incidentally it was found that the accuracy of scales and other forms of anthropometric apparatus varied greatly This serves to call attention to the possibility of serious error in judging the state of nutrition not only because of the selection of an arbitrary standard of deviation from the normal to represent underweight but also because the instruments themselves, unless carefully standardized may vary to the extent represented by such arbitrary standard

ACCESSORY MUSCLE MOVEMENTS IN DELTOID PARALYSIS*

LEWIS J POLLOCK, M D
CHICAGO

The preservation of certain movements, the loss of which is supposed to result from injury to particular nerves, has been observed for many years Sherren[1] called attention to the fact that Swan, in 1834, was astonished at observing how much a rabbit could move its leg after experimental section of its sciatic nerve Later Letievant[2] studied this phenomenon and termed it supplementary motility Since that time, numerous investigators have observed its presence in various peripheral nerve lesions

Supplementary motility producing abduction of the arm in cases of complete paralysis of the deltoid muscle has been observed in a number of cases Few reports dealing specifically with supplementary motility in deltoid paralysis are found in English literature, and mention of it is often included in contributions dealing with broader subjects It therefore seems that it is of value to confirm and emphasize this observation

The first case reported was found in the almost inexhaustible fund of observations of Duchenne[3] Since then the condition has been noted by Robert Kennedy, August Hoffman, Loewe, Kron, Rothmann, Wendenburg, Oppenheim, Ross and others, and more recently by Sherren, Forrester Brown and most of the students of injuries to the peripheral nerves sustained in the late war, including Coleman, Ingham and Arnett, and Benisty

The frequency of supplementary motility in deltoid paralysis may be seen from the report of Bunts,[4] who, in 1903, found that in nineteen cases of circumflex nerve paralysis, seven patients recovered function, of the seven, four recovered function in the absence of the deltoid muscle

I have observed four cases showing this supplementary motility

REPORT OF CASES

CASE 1—S J, a man, aged 33, was struck on the head by a cable block, Oct 5, 1920, and sustained a fracture of the surgical neck of the right humerus When he regained consciousness, he noted that he was unable to abduct the arm to the side or to extend it backward About six months after the injury he observed that he could abduct the arm in a direction slightly and obliquely forward He was examined by me, July 13, 1921, when it was found that there was a complete paralysis of the deltoid muscle, with complete reaction of degeneration and a marked atrophy of this muscle There was an analgesia of the area of skin ordinarily supplied by the circumflex nerve He was able to abduct the arm obliquely forward to the horizontal position, and from this position to complete the process of abduction to a vertical position It was observed that the infraspinatus was hypertrophied During abduction the arm was rotated outward, and the pectoralis major became tense, apparently assisting in fixation of the head of the humerus into the glenoid cavity Rotation of the scapula occurred early, and it could not be determined with any accuracy how much real abduction of the humerus occurred during the first phase of movement The last phase was completed by the pectoralis major, supraspinatus and coracobrachialis Abduction backward was impossible

CASE 2—A T, a man, aged 23, was injured, Jan 15, 1921, when a box weighing about 500 pounds fell 60 feet, striking him on the shoulder He sustained a fracture of the scapula, of the humerus and of the radius and ulna at the elbow Following the injury he was unable to move the upper extremity in any way When examined, Jan 27, 1922, he had a brachial plexus lesion involving the musculospiral, musculocutaneous and circumflex nerves In addition to this he had a severe injury to the ulnar and median nerves as the result of a lesion in the forearm For the purpose of this communication it is unnecessary to describe in detail the brachial plexus lesion, it is sufficient to note that the deltoid, biceps and coracobrachialis were paralyzed The supraspinatus, infraspinatus, serratus magnus, trapezius and rhomboidei were conserved He noted that about six months following the injury he was able to abduct the arm completely when he rotated the humerus outward at the beginning of the movement It was observed that abduction was performed by first rotating the humerus outward by the infraspinatus, then a strong contraction of the supraspinatus, pectoralis major and triceps pressed the head of the humerus

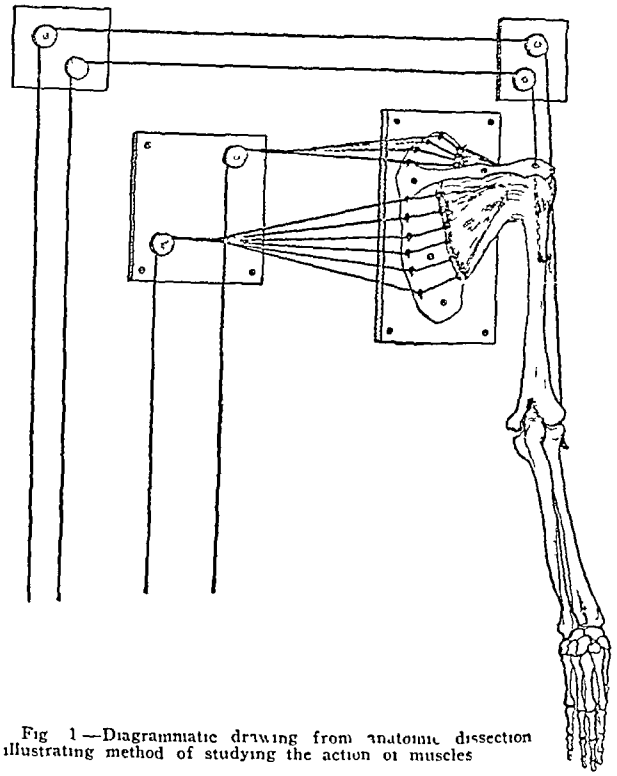

Fig 1—Diagrammatic drawing from anatomic dissection illustrating method of studying the action of muscles

into the glenoid cavity, when the scapula was rotated by a strong contraction of the trapezius serratus magnus and rhomboidei In this manner the humerus was abducted to an angle of about 100 degrees, when internal rotation occurred and the pectoralis major and probably the supraspinatus completed the abduction There was complete reaction of degeneration and almost complete atrophy of the deltoid muscle Abduction backward was impossible

CASE 3—N T, a man, aged 37, was injured, July 9, 1921, by falling a distance of 12 feet, landing on his shoulder and the side of the head Immediately afterward he found that he was unable to lift the arm, and subsequently noted that he was unable to abduct the arm except in a forward direction to a very limited degree About five months after the injury he was able to abduct the arm to the horizontal position but in an obliquely forward direction I examined him, Jan 23, 1922, when there was a complete paralysis of the right deltoid muscle with extensive atrophy, complete reaction of degeneration, and an analgesia occupying the area innervated by the fourth and fifth cervical segments Abduction was performed in three phases During the first phase

*Read before the Section on Nervous and Mental Diseases at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Sherren Lancet 1 726 (March 17) 1906
2 Letievant Traites des sectiones nerveuses quoted by Sherren (Footnote 1)
3 Duchenne Physiologie des movements 1867 p 78
4 Bunts Tr Am S Soc 21 521, 1903

the humerus was abducted, apparently by the supraspinatus, the infraspinatus, producing outward rotation of the humerus, and perhaps the coracobrachialis and long head of the biceps At about an angle of 60 degrees the scapula was rotated, as occurs normally, and the third phase was completed by the supraspinatus, pectoralis major and coracobrachialis Abduction in a backward direction was impossible

CASE 4—E D, a man, aged 45, was caught in a line shaft twenty-five years ago, and sustained a bilateral dislocation of the arms Following this he noted that he was unable

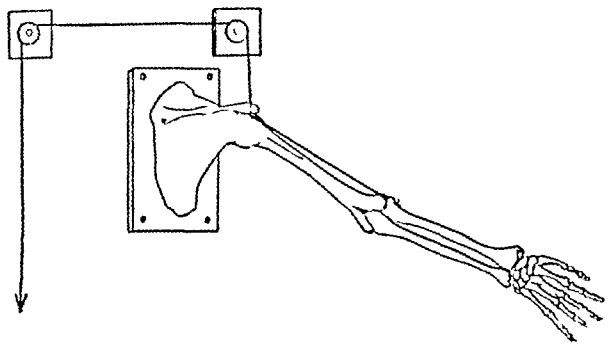

FIG 2—Abduction of arm to an angle of 60 degrees by the long head of the biceps

to abduct the right arm At the end of a year he began to draw it up along his side, shifting it backward so that he could get it into his trousers pocket About three years afterward he could abduct the arm to a right angle but could not flex and extend the forearm while the arm was in this position He continued to improve until the present date, when he stated that he experienced no disability or handicap because of the condition of his arm in the pursuit of his ordinary occupation On examination the deltoid muscle was completely atrophied The head of the humerus was covered only by skin and subcutaneous fat The capsule of the joint was lax, and a considerable space could be observed above the head of the humerus He was able to abduct his arm completely to the side and in flexion He could approximate the palms with his arms abducted fully above his head Abduction was performed in three phases, during the first of which the arm was abducted by the long head of the biceps, the supraspinatus, and in part by the infraspinatus and coracobrachialis When the arm was abducted in the position of external rotation he was unable to relax the biceps When the arm was abducted in the position of internal rotation, the biceps was seen to be flaccid, whereas the triceps became tense The second and third phases of abduction were completed about as in a normal person Abduction in a backward direction was impossible, although the patient was able to slide his hand backward and upward so as to reach his hip pocket

PHYSIOLOGY OF SHOULDER MUSCLES

The physiology of movements of muscles about the shoulder is somewhat complex, and current conceptions are obscure in some particulars and controversial in others

Until recently it was the accepted view that in raising the humerus to a straight angle, the deltoid elevates the arm approximately to a right angle, after which elevation is completed by scapular rotation This view will probably be modified through the investigation of Stookey,[5] who showed that the first cycle of elevation is accomplished by the action of the deltoid and supraspinatus, raising the humerus to about 60 degrees and accompanied by slight rotation of the scapula The second cycle is accomplished principally by rotation of the scapula due to the action of the serratus magnus, trapezius, rhomboidei and levator anguli scapulae, which raises the arm to approximately 115 degrees, and is accompanied by slight elevation of the humerus The third cycle is accomplished by elevation of the humerus from 115 degrees to a straight angle due to the action of the supraspinatus and deltoid, in which there is only slight rotation of the scapula He pointed out that the coracobrachialis and the clavicular head of the pectoralis major were associated with the deltoid in the final stage of elevation

The importance of the supraspinatus muscle was emphasized by Codman,[6] who believed that the deltoid could not act as an abductor of the arm unless accompanied in its action by the supraspinatus, whose power furnishes a fulcrum for the action of the deltoid, a view expressed in part by Winslow, in 1749 As pointed out by Stevens, the subscapularis, the infraspinatus and the teres minor act as tractors to pull the head of the humerus into the glenoid, fixing it firmly, and, beyond a certain point, the infraspinatus and teres minor behind and the subscapularis in front may possibly take on an added function, although it is probably to a limited extent namely, that of abductors as aids of the deltoid

Thus far we have seen that, in the first phase in which the deltoid is motofacient, it is supplemented by the supraspinatus and probably the infraspinatus and subscapularis, and in the third phase by the coracobrachialis and clavicular head of the pectoralis major

ABDUCTION OF ARM IN PARALYSIS OF DELTOID MUSCLE

How has the abduction of the arm in cases of complete paralysis of the deltoid muscle been explained? Duchenne showed in his case that it was the supraspinatus, the serratus and the trapezius which supplied the power, Kennedy[8] pointed out, in addition, the influence of torsion of the vertebral column Hoffman[9] considered the pectoralis major of prime importance It is the opinion of Kron[10] that the pectoralis should with the supraspinatus pull the head of the humerus into the glenoid, while the serratus by rotating the

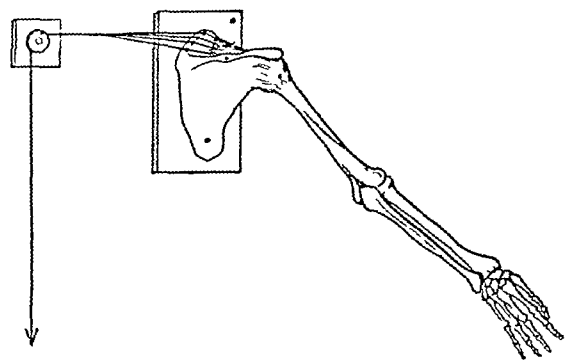

FIG 3—Abduction of arm to an angle of 45 degrees by the supraspinatus

scapula elevates the arm Loewe[11] attributed the action to the supraspinatus and trapezius Kron gained the impression that in his cases the upper part of the pectoralis major acted as a direct elevator of the humerus, aided by the supraspinatus and trapezius In one of his cases some assistance was given by the coracobrachialis and the infraspinatus

To recapitulate, the accessory muscles were the supraspinatus, pectoralis major, coracobrachialis, infraspinatus, serratus magnus and trapezius No effort has been made to determine which muscles participate in any particular part of the movement of abduction

The function of each individual muscle under normal conditions is not an indication of its limitations in vicarious function For example, the coracobrachialis and the clavicular head of the pectoralis major, acting in the first phase of abduction, would act as flexors of

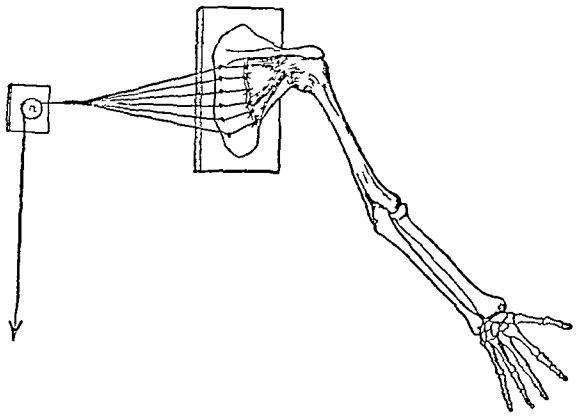

Fig 4—Abduction of arm to an angle of 35 degrees by the infraspinatus

the humerus advancing it forward, but if the forward movement be counteracted by the infraspinatus, it is possible that they may act with it to produce abduction

In an effort to understand the action of these various muscles, an anatomic preparation was made The various muscles about the shoulder and arm were resected, leaving stumps at their origin and insertion, and the joint capsule preserved intact Silk ligaments were constructed, attached to the insertion of the muscles and passed through rings at the point of origin, then through pulleys permitting traction in the direction of the normal action of the muscles The shoulder blade was then screwed firmly to a support (Fig 1) It was postulated that the contraction of a muscle could produce a movement only so extensive as would be shown by the angle remaining between the humerus and a vertical line after the muscle had been subjected to strong traction, and the humerus abducted passively to the vertical and slowly allowed to fall to the position at which the stretched muscle would support it It was seen that the long head of the biceps acted as a direct abductor to an angle of 60 degrees, that the supraspinatus acted as an abductor to an angle of about 45 degrees, that the infraspinatus produced an abduction of 35 degrees, accompanied by an outward rotation of the humerus and slight backward movement, and that the coracobrachialis brought the arm obliquely forward and upward to an angle of about 30 degrees The combined action of these muscles elevated the arm to an angle of about 65 degrees It was found that when the infraspinatus and coracobrachialis acted together, the former tended to counteract the forward action of the latter It was further found that when the arm was passively abducted to a position sufficient to permit the tuberosity of the humerus to pass under the acromial process, and when both the coracobrachialis and the infraspinatus were pulled on, the humerus retained this position, when the coracobrachialis was released, the arm fell to an angle of 35 degrees, and assumed a position of outward rotation (Figs 2, 3, 4 and 5)

From the observation of the clinical cases and the anatomic model, it would appear that there are two distinct types of supplementary motility which permit abduction of the humerus in complete paralysis of the deltoid muscle Of course, the movement of torsion or bending of the spine need not be included, since it only increases the distance between the dependent hand and the ground, and in no way abducts the humerus

The movement of abduction backward seems never to be supplemented, so that such a movement as is necessary to put one's hand in the hip pocket is impossible, although Kron stated that the teres major can supplant the action of the posterior belly of the deltoid His description of the resulting movement is unconvincing

The first type of supplementary movement is that in which the head of the humerus is firmly fixed in the glenoid cavity, probably by the subscapularis, the infraspinatus, the pectoralis major and the supraspinatus During this phase, external rotation of the humerus occurs The serratus magnus and trapezius, with the rhomboidei, and levator anguli scapulae, then produce a rotation of the scapula, elevating the humerus, some actual abduction may likewise occur Thus, the first and second phases of abduction are combined, but the second phase overshadows the first The third phase may be concluded by the supraspinatus, the clavicular head of the pectoralis major and the coracobrachialis (Cases 1 and 2)

The second type is that in which the first phase of abduction of the humerus may occur as the result of the combined action of the supraspinatus, the infraspinatus probably acting in conjunction with the coracobrachialis and possibly the long head of the biceps, the second phase of abduction occurs as in the normal by the action

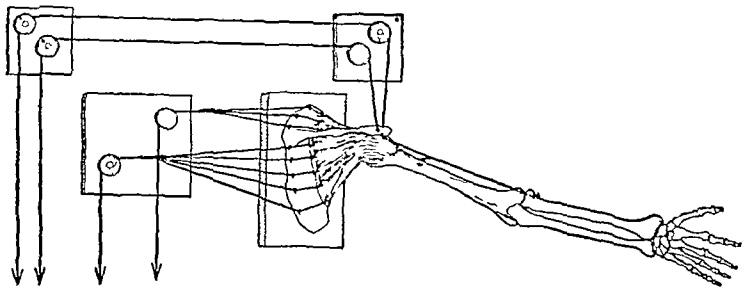

Fig 5—Abduction of arm to an angle of 65 degrees by the combined action of the coracobrachialis long head of the biceps supraspinatus and infraspinatus.

of the serratus magnus, trapezius rhomboidei and levator anguli scapulae, the third phase is completed by the coracobrachialis, the clavicular head of the pectoralis major and the supraspinatus (Cases 3 and 4) Of course, any one or more of these muscles may not participate in a given case

Fixing the Mental Status of an Antivivisectionist—"I have no hesitation in calling him—Pasteur—the greatest charlatan of the last century" This is the matured opinion of Pasteur held by Dr Walter Hadwen of Gloucester England the leading antivivisectionist of Great Britain, who recently made a tour of propaganda in the United States It will be found in the *Starry Cross*, October, 1921 p 154

DETERMINATION OF DISABILITY AS TO LOSS OF HEARING, AND THE IMPORTANCE OF VERTIGO

IN INDUSTRIAL ACCIDENT CASES *

HAROLD A FLETCHER, M D
SAN FRANCISCO

A review of the files of the Industrial Accident Commission of California reveals the fact that during the last few years more than $60,000 has been awarded as compensation for disability due to accidents involving the ears These files convince one that the average specialist either considers his reports to the commission or insurance company as unimportant, or that he has no conception of what is wanted by them

If a man has an injury of his ears and is to receive compensation for it, a report must be sent to the commission or to the insurance company The report must give certain facts before the company will pay the compensation Briefly these facts are

1 A diagnosis of the trouble
2 What the cause of the trouble is or was, particularly whether caused by the alleged accident
3 The loss of function, if any, estimated in such a way (percentage preferably) that the accident commission can rate the man and the man be paid for his loss

If the specialist will try to fulfil these three things in his reports, the patient and the insurance company will both receive fairer play

In regard to estimation of the loss of hearing, I find that at present it seems to be pure guesswork I have found reports on the same case from three different physicians differing as widely as 65 per cent when each physician was using the same tests

TABLE 1.—TESTS OF HEARING AFTER CONCUSSION INJURY TO LEFT EAR

Right ear	Left or injured ear
5 meter watch at 3 meters	5 meter watch on contact
Whisper more than 5 meters	Whisper 50 cm
Voice more than 5 meters	Voice, more than 5 meters
Rinne, plus	Rinne plus
Air conduction greater than bone conduction	Air conduction greater than bone conduction
Bone conduction normal	Bone conduction lightly shortened

Weber referred to right

Tuning fork test averaging all forks

Right	Left
C = 48%	C = 55%
C_1 = 50%	C_0 = 40%
C_1 = 60%	C_1 = 35%
C = 50%	C = 10%
C_3 = 50%	C_3 = 40%
C_4 = 80%	C_4 = 70%
C_5 = 100%	C_5 = 0%
Average 60%	Average 40%

Differing from the estimation of the loss of vision there has been, so far as I know, no method of determining the percentage loss of hearing [1] The recent developments of the audiometer and the electric acoumeter may eventually become practical in this respect We have certain tests on which we base our judgments, namely, the watch or the acoumeter, the spoken voice, the whisper, the Galton whistle, tuning forks, monochord, etc, and the Weber, Rinne, Schwabach and other tests, which give us a line on how much a man hears, and whether it is a middle or internal ear condition It is difficult, however, to take the results of these tests and fairly estimate what percentage of hearing has been lost

I believe that there should be some system used in estimating these cases, and that such a system should be universal I have gradually worked out a plan which I am using and which is best explained if applied to an actual case

TABLE 2.—ESTIMATION OF LOSS OF HEARING IN LEFT OR INJURED EAR

Normal Hearing	Patient Hear	% Loss		Weight		Total
Watch 5 meters	on contact	99 8	×	10	=	998 0
Whisper 5 meters	50 cm	90 0	×	30	=	2 700 0
Voice 5 meters	5 meters	0 0	×	50	=	0 0
Forks 100%	40%	60 0	×	10	=	600 0
				Total	=	4 298 0

4 298/100 = 42 9 or 43% loss of hearing

A patient who had a concussion injury of his left ear was tested, with the results given in Table 1

With these data I roughly estimated his loss of hearing at 57 per cent in the left ear I did this by averaging all the tests on an equal basis

If a man loses his hearing in one ear, he obviously loses 100 per cent in one ear If, however, he hears with his injured ear watch on contact, instead of 5 meters whisper at 50 cm instead of 5 meters, and hears the tuning forks 40 per cent of the normal, how are we to arrive at his actual disability? For the watch, his loss is 99 per cent , for the whisper, 70 per cent , for the voice, 0, for the tuning forks, 60 per cent Averaging them gives us 57 per cent loss of hearing This is much too high, as the watch tick, which is only one unimportant test, brings up his disability, whereas the spoken voice and the whisper, which are the important things in his daily life, do not show great enough impairment to cause great disability A machinist who adjusts delicate machinery needs much more accurate hearing than the laborer or mine worker who needs his ears for spoken orders and as a protection for himself and others against dangers It occurred to me that a scale of weights could be used, rating the man on the different hearing tests, but putting more weight on the important ones One patient may hear a 5 meter watch tick only on contact, and hear a whisper at 5 meters Another hears a watch at 25 cm , and hears a whisper only at 2 meters

By a scale of weights is meant the taking of a total of ten or a hundred as the total for a man's hearing, and then dividing this into different parts according to the importance of the tests as far as his work is concerned Thus, if 100 is the total, the voice being the most important, 50 could be made the weight for the test, the whisper being next could be placed at 30, and the watch and tuning forks at 10 each Taking this as the normal we would estimate the foregoing case as in Table 2

Multiplying the percentage loss by the weight given to each test, and dividing the sum of these by 100, gives 42 9 or 43 per cent estimated loss of hearing

* Read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Holt F E Economics of the Eye Ear Nose and Throat Tr Am Acad Ophth & Oto Laryng 1914

Figuring out the right ear on this basis we find 8 per cent loss of hearing (Table 3)

In this patient the loss of hearing due to the accident should be based, not on normal hearing but on what he could be supposed to have heard before the accident In other words, the hearing in his right ear should be considered his normal hearing Thus, the loss of hearing due to the accident would be 43 per cent minus 8 per cent, leaving 35 per cent loss of hearing in the left ear due to the accident This I believe to be a much fairer estimate of what this man lost, as far as his disability is concerned in his particular work It will be noted that I originally estimated this at 57 per cent

TABLE 3—LOSS OF HEARING IN RIGHT EAR

Normal Hearing	Patient Hears	% Loss		Weight		Total
Watch 5 meters	3 meters	40	×	10	=	400 0
Whisper 5 meters	5 meters	0	×	50	=	0 0
Voice 5 meters	5 meters	0	×	50	=	0 0
Forks 100%	60%	40	×	10	=	400 0
				Total	=	800 0

800 divided by 100 = 8 per cent loss of hearing

The main point to be borne in mind is, that we should have one system by which to figure the percentage of disability, and then use that system in all cases I submit this not as an absolute final scheme, but for discussion There is to be decided first normal hearing and then what weight should be given to each of the various tests Furthermore, a watchmaker or an adjuster for delicate machinery should probably have a greater weight put on the watch tick and the tuning fork test at the expense of the weights on voice and whisper

VERTIGO

The next point is the symptom of vertigo following head injuries, such as fractured skull and concussion of the brain These patients often complain of several major symptoms lasting for a long period, namely, vertigo and instability, headaches, weakness, deafness, nervousness and a great many minor troubles Unless these patients are found to have definite evidence of an organic neurologic condition, they are placed in a class of functional disorders, namely, traumatic neurosis Until recently the otologist has not been consulted enough in these cases

The point that interests us as otologists is the fact that quite a number of these cases which are otherwise neurologically negative show very definite evidence of organic disturbance along the vestibular pathways The neurologic examination, therefore, should not be considered complete without a thorough neurotologic examination If the examination shows definite evidence of disturbance along the vestibular pathways these findings may be of the greatest help to the neurologist in differentiating between the functional and the organic cases

There are certain things to be kept in mind in making a neurotologic examination in these cases 1 Careful technic must be employed and any abnormal responses must be checked up 2 We must be guarded in the interpreting of our result One of the greatest criticisms of these tests, and justly so, is that otologists have attempted to go too far in their interpretations [3] 3 A great many of these cases show a big neurotic element, and it is well to remember that there have been a goodly number of cases reported in which abnormal reactions have been hysterical manifestations [4] Malingerers are encountered, and certain responses in these tests can be faked

REPORT OF CASES

The cases here reported were cases of head injuries which were neurologically negative, and therefore suspected of being functional or true traumatic neurosis, in which positive evidence of organic trouble was found as far as the vestibular apparatus was concerned

CASE 1—V S T, a man, received severe head and body injuries in June, 1918 He was referred in September for rating for hearing He complained at this time of headaches weakness and dizziness which had been pronounced a part of a traumatic neurosis by several other physicians Neurologic examination was reported negative

Hearing was reduced in both ears, of the nature of middle ear rather than internal ear type

Neurotologic examination revealed (1) spontaneous rotary nystagmus to right and to left when looking in those directions (2) spontaneous past pointing of the right arm 2 inches to the right and of the left arm 1 inch to the right, (3) turning to right, long continued past pointing but correct direction, (4) turning to left, long continued past pointing to *right* (5) caloric test right ear, responses within normal limits, (6) caloric test, left ear, past pointing to *right* and a perverted nystagmus (7) right arm, no past pointing to left on any stimulation

These responses I believe to be evidence of an intracranial, rather than a peripheral disturbance These would also be evidence of an organic cause for his complaint of vertigo and instability

Reexamination in December, 1920, disclosed practically the same abnormal responses except that the spontaneous nystagmus had disappeared

In May, 1921, the patient still showed the same abnormal responses

In October, 1921, he still showed the same abnormal responses

During this time the patient was improving generally as to the neurotic element and ability to negotiate work, and his dizziness bothered him less

CASE 2—M W a man, received severe head and body injuries in April 1921 He was referred in September, 1921 when his chief complaint was dizziness and headaches when attempting to do even light work, also constant tinnitus of the right ear

Neurologic examinations by three neurologists were practically negative

Examination revealed marked impairment of hearing in the right ear of internal ear type, and slight impairment of hearing in the left ear of middle ear type

Neurotologic examination revealed that (1) there was spontaneous past pointing of the right arm to the right, (2) turning tests could not be carried out as the patient could not hold himself in the chair (3) responses to caloric stimulations were somewhat delayed, (4) stimulation of the right vertical canals caused spasmodic twitching of the body and extremities which was more marked on the right side, (5) stimulation of the right horizontal canal caused nystagmus to the *right* and a tendency to conjugate deviation of the eyes to the right, (6) stimulation of the left vertical and left horizontal canals produced past pointing of the *right* arm to the *right* and subnormal past pointing of the left arm to the left, (7) the right arm could not be made to past point to the left on stimulation of any canal

Reexamination in March 1922 revealed practically the same responses although the patient was still neurologically

3 Weisenburg T H Traumatic Neurosis in War and Peace J A M A 78 596 (Aug 23) 1919

4 Sewall F C Demonstration of Case of Hysteria Simulating Brain Tumor Tr Western Sec Am Laryngol Rhinol & Otol Soc., Feb 23 1922

negative He still complained of dizziness, instability and headaches

In March, 1922, examination by Dr F C Lewitt revealed practically the same abnormal responses that I found

CASE 3—A W, who received severe head and body injuries in May, 1919, was referred in August as a possible malingerer

Examination revealed complete loss of hearing in the right ear and normal hearing in the left

Neurotologic examination revealed (1) spontaneous rotary nystagmus to the right on looking to the right, and to the left on looking to the left, (2) spontaneous past pointing 2 inches to the right with the right arm only, (3) turning test subnormal nystagmus, perverted past pointing of the left arm on turning to the right, subnormal and perverted past pointing of the left arm on turning to the left, falling after turning, much impaired in both directions, (4) caloric test of right ear, reactions absent except that stimulation of right horizontal canal caused a past pointing of the left arm to the *left* (5) caloric test of left vertical canals absent, nystagmus and past pointing after five minutes, left horizontal canal, normal responses

Reexamination in October, 1919 gave findings the same except that there was no spontaneous nystagmus The Wassermann reaction was positive at this time A thorough examination by a neurologist at the time was negative Nothing gave definite evidence that syphilis was complicating the injury

It is to be noted that Weisenburg[5] has reported a case similar to Case 2 in which the symptoms cleared up on settlement for damages It was not stated whether later neurotologic examination was made This is important, I believe, for the reason that as yet we do not know how long these abnormal reactions remain in these cases Further, we do not know, as yet, the exact relation these responses bear to the symptoms of vertigo and instability in these cases Lump sum compensation in the true traumatic neurosis case will often clear up a great many of the symptoms[6] If settlement will clear up the symptoms in cases in which evidence shows central organic disturbance, as in the foregoing cases, then we must revise our ideas as to what constitutes evidence of organic disturbances These things we do not know yet, but these tests, repeated over long periods, will clear up the question No matter what the answer, these tests must be considered important and should be made more often in these cases

CONCLUSIONS

1 More thorough examination, deeper thought and more careful analysis of industrial injuries involving the ears, and more comprehensive reports to the insurance companies should be the physician's endeavor

2 It is believed that the hearing can be more fairly estimated by a system of weights proportionate to the value of the tests for hearing

3 The neurotologic examination should be made of all patients with head injuries complaining of vertigo, as the findings in these examinations may be the only evidence by which the neurologist can differentiate the traumatic neurosis from those cases in which there are central organic disturbances

4 These patients should be reexamined over a period of years, if possible, to determine the relation of the duration of the symptoms to the duration of his abnormal reactions

ABSTRACT OF DISCUSSION

DR CHARLES G STIVERS, Los Angeles With the growth and development of industrial medicine, insurance companies and state accident commissions have demanded that physicians estimate the loss of function systematically and accurately Otologists are behind in this particular work, as they have not as yet produced any method by which it is possible to estimate the percentage of hearing lost Offhand, this would seem difficult to do, as our judgment of hearing is based on several different tests, each of which has a different value, but practically it is interpreted in terms of the amount and quality of function required in a given occupation compared to what remains in any given case This paper is an attempt to arrive at a fair estimate of what a patient has lost Any method must be purely an estimation, but such an estimation should rule out 'guesswork" as far as possible Furthermore it should be simple and clear So far as I know, there has never been any such method produced This plan would seem to me to be a reasonable and fair one, it is easy to follow out no matter what the tests used It has the advantage, furthermore that the weights used can be changed in certain cases in which a man's occupational efficiency is more dependent *auditorially on certain sounds, in the upper, middle or lower* tone scale for instance in machinists, stenographers, salesmen watchmakers musicians and teachers appreciation of the difference in upper and lower tone scale is necessary The second part of the paper deals with the importance of vertigo following head injuries If the neurologist can get definite evidence of organic disturbance in the brain in these cases it helps him to separate these disturbing cases The importance of careful vestibular examination in such cases is demonstrated in the examples shown These cases were otherwise neurologically negative It is to be noted that Dr Fletcher has not attempted to localize the lesions, but has confined himself to saying that evidence points to an intracranial rather than a peripheral disturbance This, I believe is both safe and conservative Systematic examination of the amount of hearing, as well as eyesight and other evidences of physical condition of all employees, would seem to be necessary to find out what the real loss from injury is in a given case It might become necessary to have such a record of every employee when starting to work

DR JOHN A DONOVAN Butte Mont As Dr Stivers has said from the economic standpoint you have to put in another factor—occupation I had a railroad dispatcher sent to me for examination because the chief thought that the man was not able to hold his postion I suggested that he be taken away from the telephone and be given service as a telegrapher With a certain kind of voice he was unable to hold his position, but in telegraphy that factor did not come in Dr Fletcher is aiming to get under ordinary conditions, with ordinary people just what hearing they have lost His propositions appear to me quite reasonable But the big factor about the paper is that it gives us a key to start working and in a few years we can arrive at something quite definite

DR GEORGE E SHAMBAUGH, Chicago This is by no means a simple problem I have had a good deal of experience in examining patients who were supposed to have sustained injury to the hearing It is important in such cases to remember, first that it is a very common thing for people to believe that by feigning a defect in the hearing they will be able to get damages for supposed injuries, another is, that when we come to examine the hearing even when we are convinced that there is a defect we must always take into consideration the question as to whether there has been some defect previous to the injury Dr Fletcher tries to work out a system by which this can all be checked up I was stationed at Camp Grant during the most active demobilization period, and I was called to pass on a great many cases in which there was some apparent defect in the hearing and to determine whether this defect could be the result of war injuries There are two ways by which the hearing may be injured by traumatism One is by concussion, that is explosions near the ear, the other is by an injury from a blow on the head Now let us consider a moment what is the nature of the injury

to the ear in these two conditions Concussion may or may not rupture the drum membrane Explosions near the ear may result in a partial or complete loss of hearing After an injury of this sort a partial or a complete restoration of the hearing may take place When there is a defect due to a fall or blow on the head we may again have a rupture of the drum membrane or an injury to the internal ear In cases resulting from a rupture in the drum membrane, only a temporary slight impairment is experienced The big question in most of these cases is whether or not the head injury has resulted in a traumatism to the labyrinth My own opinion is that an injury to the labyrinth from a blow on the head is always the result of a basal skull fracture Such injuries destroy completely and permanently the function of the internal ear so that the patient experiences not only a total loss of hearing in that ear immediately after the accident but also a marked disturbance of equilibrium vertigo and nausea I have never been convinced that a blow on the head can result in only a partial loss of hearing As far as the intracranial lesions are concerned which may affect the hearing center these are still more problematic than the supposed injuries to the labyrinth resulting in partial loss of hearing I studied one case rather carefully at Camp Grant, in which the patient had an injury in the temporal region from a bullet wound and I was convinced that an injury to the hearing center in the cerebral cortex was the cause of the defect in the hearing

DR J W CHARLES St Louis I want to disagree with Dr Shambaugh that a blow on the head causes entire loss of hearing A young girl fell on the ice She was not unconscious but dizzy She came the following day with a bloody infusion into the middle ear This promptly cleared up and gave her absolutely normal hearing with no internal ear inflammation On the day I first examined her there was no discoloration of the skin back of the ear This appeared the following day and persisted for several days I was very glad to hear Dr Fletcher present this paper because I think this subject is one on which we need enlightenment and possibly some way of coming to conclusions on which to base our findings to the industrial commission in accident cases I had a case of a structural iron worker who was struck on the head by a beam and was unconscious for several hours He recovered but still complained of dizziness Brain tests were normal but he still complained of dizziness, and certainly it was impossible for him to undertake any such hazardous occupation as that of structural iron worker Dr Fry of Vienna was here at the time and I had him see the man He brought out the point that if the injury had been complete so that there was a complete loss of function of the labyrinth on one side the man ultimately could have engaged in his occupation, but since the injury was not complete but only irritative, the probability was that his dizziness would never disappear

DR WILLIAM HOUSE Portland, Ore The neuropsychiatrists are a forgiving group Years ago the oculists took our headache cases and the gynecologists took the female half of our practice among the insane Then the dermatologists started to cure our paretics and tabetics, and now it looks as if the otologists were trying to take what little we have left This time I think that most neurologists are in sympathy with them, believing that they are the right people to make the tests under discussion The otologist alone has the correlated knowledge of the labyrinth which is essential if one is to make these tests correctly But I think that we need these tests in relatively few cases Dr Fletcher has presented an idea that seems worthy of further investigation Many patients with head injuries have no neurologic symptoms excepting vertigo This vertigo is increased by bending the head forward or backward and I believe that it may be due to alterations of tension of the cerebrospinal fluid The head-neck articulation is in close proximity to the anterior and posterior cisterns which are filled with cerebrospinal fluid, and it is quite likely that changes in position may cause alterations of tension which may extend along the sheath of the auditory nerve or possibly to the endolymph of the semicircular canals themselves Of course, if there is any injury in the region of the canals or at the base of the brain it could readily influence the sensitiveness of these parts to changes in position If the Barany tests are to be used in traumatic cases, care should be exercised The tests themselves may constitute additional trauma in neuropathically inclined persons, and such results may be construed as due to the original accident Especially when suit is to be instituted they should be cautiously used or not at all at least until their value has been determined in traumatic cases not in litigation I congratulate Dr Fletcher on giving us a new thought that there may be a relation between traumatic neurasthenia with its attendant vertigo and the vestibular apparatus which may be cleared up by the Barany tests I shall try to apply his observations in some of my own cases

DR M A GOLDSTEIN, St Louis As I understand Dr Fletcher's paper, he is endeavoring to develop a system of calculation of the percentage of hearing That percentage is possible in some of the tests as, for example, in the voice, but I am not enough of a mathematician to follow his calculations of the percentage of hearing in the use of the tuning fork There are no two men who handle the tuning fork alike and before you can get a definite percentage calculation in the use of the tuning fork you must standardize the tuning forks and their methods of use

DR HAROLD FLETCHER, San Francisco In reply to Dr Shambaugh of course this paper presupposes that you have made a careful examination and taken a careful history In these cases we must take a particularly careful history as this may be of greatest importance in deciding whether the accident caused the deafness Dr Shambaugh states that it is his opinion that a blow on the head will cause either complete loss of hearing or no loss at all, with the exception of deafness due to concussion through the middle ear I think that if one will look over the reports of head wounds during the war one will find that complete or partial loss of hearing has followed wounds of the head without destruction of the vestibular apparatus I had three of these cases myself The length of time vertigo remains after destruction of the labyrinth or eighth nerve has been pretty well worked out and is comparatively short In traumatic neurosis cases, following head injuries, however vertigo is complained of for as long as three or four years Most of these cases show no evidence of organic intracranial lesions as far as the neurologic tests are concerned Some of them do as in the cases mentioned These tests, then are of greatest importance in differentiating between those having an organic basis for the vertigo and those which are purely functional Certain abnormal responses to these tests have been taken to mean organic intracranial lesions If the vertigo clears up after settlement in these cases we shall be forced to revise our opinions As to the tuning fork tests that Dr Goldstein mentioned, this of course presupposes that one is making careful tests and one knows one's own tuning forks The growth of industrial medicine and the compensation of injured employees is making more demands on the medical profession If otologists report that a man has a loss of hearing due to an accident the commission is promptly going to ask "What per cent?" The ophthalmologist has produced methods for estimating loss of vision It is up to otologists to do the same for hearing, otherwise we are put in a very poor light

---

Factors of Safety—Every normal individual has within himself large factors of safety If much of the normal margin of safety is consumed before injury then so much the more readily does the wound produce what is called shock On the contrary, a soldier wounded soon after his arrival at the front, while he is still fresh may show no immediate shock—for shock appears only after the factors of safety have been consumed, just as the Marathon runner is not exhausted at the beginning but at the end of the race Tens and hundreds of thousands of troops en bloc may be in a state of chronic exhaustion or in a chronic state which predisposes to shock It may take a serious wound and the lapse of hours to reduce a fresh soldier to the shock level of the battle exhausted soldier without a wound There is probably no ultimate difference between the exhaustion produced by the privation and stress of war, and that produced by the bodily injuries of war—G W Crile "A Physical Interpretation of Shock, Exhaustion and Restoration, 1921

NEED OF STANDARDS OF TRAINING

FOR SPECIALISTS, GENERAL PRACTITIONERS AND TEACHERS OF SPEECH CORRECTION *

CHARLES G STIVERS, M D
LOS ANGELES

Every one whose practice has anything to do with children realizes that the time is ripe for the development of a program for the study of the problems of defective speech, for about 5 per cent of all children have some form of speech disorder Institutions, boards of education and child welfare centers everywhere are asking for physicians to enlighten them on *the prevention and correction of speech disorders*

Disorders of speech are increasing, partly because of the great revival of interest in education since the World War, as our system of public school training favors the production of more crowding, more psychoneuroses and more defects of all kinds, including speech disorders Many foreigners in the larger cities who are learning to speak English at school are forced to speak their native language at home, this conflict often produces some form of speech defect The World War has been followed by a large number of psychoneuroses many with some form of speech defect, and this condition has helped to focus attention on the prevalence of speech disorders in adults, and compelled a better understanding of their frequency and importance

There are about 1,000,000 children with speech defects in the United States, and the problem is a serious one because these children must go to school while having corrective methods applied But at present there is no agreement among teachers as to the best methods to use, and physicians are not yet, as a body, sufficiently qualified to establish standards of diagnosis, pathology, prognosis and treatment

In the training of physicians to diagnose and treat these conditions, it is evident that some form of differentiation must be made in the amount and character of the training 1 What shall the medical college offer the undergraduate? 2 What shall constitute or be considered an adequate amount of time to be devoted by a physician who wishes to become a specialist in speech, and of what particular subjects shall his training consist? 3 How shall teachers of speech correction be trained?

It is suggested that the premedical period of study should contain more psychology, introductory, general and genetic, with a survey of mental development in children and adolescents Abnormal psychology, including mental deficiency, truancy, mental measurements and the psychology of backward and abnormal children—there are 5,000,000 abnormal children in the United States, according to Lightner Witmer—must also be a part of the special training Where in the curriculum these subjects can be introduced, in the premedical or undergraduate school, I do not attempt to say That is a question for a committee to decide I suggest only what I consider to be necessary training

The specialist requires, in addition to general knowledge, a much more intensive training than would be necessary for undergraduate students who should be required to know something about the diagnosis, prognosis and treatment of a case of disordered speech, but should not, unless specially trained and of proper original endowments, undertake the cure by corrective training methods The specialist should be a physician who has had some special training in artistic voice and speech production, and in the diagnosis and treatment of the functional derangement as well as the pathologic conditions of the voice and speech producing organs The present lack of competent advisers is responsible, *in a large measure, for the great number* of untrained voice teachers who ruin untold numbers of voices and cut short many a promising vocal career There are many physicians whose language and temperament unfit them for special corrective work with children with speech troubles For instance, a foreigner who speaks English with a foreign accent is not a good example for children to imitate Especially is this true in cases of lisping, substitution and oral inactivity The specialist should have had in his premedical training a thorough course in psychology, and, in his special work, he should become proficient in the diagnosis and treatment of the diseases of the nervous system, especially in children, and of the affections of the ear, nose and throat, since the psychology of speech is a linking together of the psychology of the phonatory, articulatory, respiratory and auditory systems Because of the very large numbers of backward, subnormal and deficient children who have defective speech, the training in both normal and abnormal psychology is absolutely necessary for the specialist

The intelligence tests employed in the World War showed that 45 per cent of those who were examined, or about *one half of the total male population*, had a mental capacity or natural ability that would never develop beyond the stage normal to a 12 year old child They are doomed to remain forever subnormal[1] As there are many millions of our population who are mentally deficient, every medical graduate should be able to recognize mental deficiency in his practice, for several reasons, one of which is that a large number of subnormal persons have speech defects It is essential that persons with speech defects be graded mentally in order to do them justice in a social sense, so that the corrective methods applied to them, which may be followed by an anticipated result for speech training will not be expected either to raise or to lower mental capacity Medical schools should teach the relation of the teeth to phonetics, the role of dental irregularities, and the relation of malocclusion and cleft palate to language ability

Recent studies reveal speech difficulties in the fields of orthopedics and pediatrics My investigations show that there are twice as many cases of speech disorder among physically handicapped children as among normal children of school age The speech training of these children will demand teachers who have special knowledge of physiotherapy and vocational guidance *and a comprehensive knowledge* of the application of systematic training as a means of reaching mental levels Teachers who wish to apply corrective methods should have the following qualifications

1 They should be graduates of a normal school, college or university in which there was sufficient instruction in normal and abnormal psychology to prepare *them* for the understanding of the problems of defective speech

2 They should be naturally endowed with an aptitude for handling nervous children

* Read before the Section on Otology Laryngology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922 in connection with the film Development of Speech and the Use of Speech Drill in Orthopedic Cases

1 Berman Louis The Glands Regulating Personality

3 They should be quick in auditory perception, should have well trained voices, and should be able to impart their knowledge to others

4 They should be possessed of poise, patience and a love for the exacting demands of their careers

5 They should be trained in corrective gymnastics and be able to diagnose the commoner forms of bad posture, notably, faults in spinal alinement and foot and leg conditions, and they should be able to apply their knowledge of corrective exercises in the curing of respiratory and developmental faults

6 They should understand phonetics both in the organic and the acoustic sense, and they should have some training in diction, dramatics, public speaking, elocution and class management

We acknowledge the fact that it is better to prevent than to attempt to cure, so it is recommended that large cities have child welfare centers, preferably connected with, or the work supervised by a staff of, a university medical school or hospital A speech clinic, as an integral part of such a center, should have as director a physician who has been trained as a specialist in the diagnosis and treatment of speech disorders The consulting staff working with him should consist of specialists a pediatrician a neuropsychiatrist an ophthalmologist an ear, nose and throat specialist, a dentist with special knowledge of orthodontia, an orthopedic surgeon, and an endocrinologist, who might also be the pediatrician

Our language, English with American modifications, changes from generation to generation A word may have one sound today and a totally different one in fifty years, or a modified sound in different parts of the United States, because there never can be any arbitrary standard for pronunciation for the whole country Our aim, as speech defect specialists, must be to provide a standard of correct speech production, so that the children of today may have the ability to express their ideas in fluent English, and have no hesitation over word utterance We must cooperate with boards of education to obtain these desired conditions Accordingly, it would be wise to have a teacher of normal speech associated with a group of speech specialists The corrective methods should be applied by assistants, either men or women, with the necessary natural endowments already referred to, trained in the practical application of corrective methods, including the reeducation of the deaf

It will be necessary for those of the medical profession who are now trained as specialists of speech disorders to agree among themselves, after conferences discussions and trials of methods, on a program for a comprehensive study of the entire field of oral expression After this is accomplished, they must interest the men in the medical profession, as a body, by showing the need for a better understanding of the problems of defective speech, in a national campaign for better training of all physicians, specialists and teachers When medical schools realize that the demand exists they will inaugurate courses in this field, and the training of physicians in this specialty will no longer be subject to the criticism it now merits, because of its lack of recognized, accepted and practical standards So-called schools which guarantee to cure speech defects, if the students live up to every one of the multitude of rules and restrictions, usually impossible to follow, will be replaced by standardized methods The stammerer especially will be taught by reeducation and training to adapt himself to his home surroundings not sent away to be "cured" and then returned to his home to become again a stammerer

SUMMARY

The time is favorable to the development of a program, by the medical profession, for the study of the serious aspects of, and the correction of, speech disorders

Five per cent of all children have speech defects, *calling for correction*

Speech defects are increasing, owing to revival of interest in primary education, with overcrowding, competition, psychoneuroses and foreigners

The World War has produced many psychoneuroses, many with speech difficulties

The orthopedic and psychiatric fields furnish many cases

The medical profession, as a whole, is not qualified as yet to establish standards of speech correction

It is necessary for those now trained in the theory and practice of speech correction to agree on standards to begin a program of education of the men in the medical profession, and to secure cooperation of educators

When medical colleges realize that a need exists, adequate facilities for training will be offered to undergraduates, specialists and teachers

The nature and scope of the training must be determined by committees, conferences and discussions

406 Auditorium Building

ABSTRACT OF DISCUSSION

DR M A GOLDSTEIN St Louis This is the first time I have ever had the opportunity of seeing corrective speech demonstrated when it could also be definitely studied with a slow motion camera I was much impressed in Washington a few weeks ago at the work done experimentally on the labyrinth of animals and the splendid demonstration by the slow motion camera of the removal of the labyrinth under different conditions, and the action of the slow motion camera in the study of this unusual series of changed musculature I congratulate Dr Stivers on the philosophy he has presented in the relationship of individual spastic muscle conditions to the general muscle contraction that one finds in so many of the larger groups of crippled children I should like to know what proportion of the patients Dr Stivers examined have defects in speech The medical man in his study of speech defects and their correction not only must consider the mechanical element of correction, but also ought to be a fairly universal specialist in the study of his cases He must study the psychology he must know anatomy, physiology and speech machinery he must know the relation of breathing to the muscles of the mechanics of speech, he must know the peculiar adaptability of the defective child to its defects, and he must know the pedagogy with which these defects are definitely improved It is not such an easy thing to go into a room where corrective speech patients are being given instruction, make a few observations, and go away feeling that one has studied the situation thoroughly One cannot make an expert in handling corrective speech cases over night, any more than one can make an expert otologist over night An expert, whether teacher or physician should know anatomy, physiology and pathology, besides the mechanics that go into the correction of the speech defect

DR ELMER L KENYON, Chicago I have had a little experience with the spastic child with reference to the speech problem The problem is prodigious, and I congratulate Dr Stivers on having had the courage and intelligence even to attempt to tackle it on a large scale I should like to ask him to state more definitely what results he is able to get with children who are distinctly spastic in the mouth region Dr Stivers' demonstration points clearly to the fact that speech disturbance is not a laryngologic problem alone *Dr Goldstein*

brought out that point I venture to say that etiologically 90 per cent of the cases of speech defect have their cause in the brain They go into the field of the psychologist, the psychiatrist and the child specialist If we focus our attention too closely on the mere treatment of disorders of speech we may forget the larger problem the distinctively medical problem, i e etiology and prevention We are developing a most interesting system in the public schools of treating defects of speech a most valuable thing, and yet if we are not careful it will be so superficial that we shall have largely to do it over The foundations of defects of speech have occurred long before the school age These defects should usually be attacked when they are beginning It seems to me that we as physicians should endeavor to strive to advance speech problems largely from an etiologic standpoint and a preventive standpoint, and that for the largest success the psychiatrist and the pediatrician must be brought definitely into the problem

DR DENNIS J MCDONALD New York Years ago I was one of the commissioners of education in New York and introduced this work in public schools and today I am much pleased and take new heart because of the work of James Sonnet Greene He has founded a national hospital for the cure of speech defects This is a wonderful demonstration we have had today It is a work for the nation and for the women

DR LOUIS K GUGGENHEIM, St Louis I want to subscribe most heartily to the statement that this is a tremendously important subject, but I want also to sound a note of warning This work is not for the otolaryngologist A few years ago, feeling the necessity for some one to do something for these patients, I went to Europe to study the subject, naively ignorant of the size of the problem I was going to practice otolaryngology, and in my spare time treat speech cases I opened a clinic at Washington University, and had a sign painted Speech Defects' Being connected with the ear department I could spare only three afternoons a week for the speech clinic I had two patients to begin with the next week there were five the next ten then fifteen and finally I was overwhelmed This was not because I knew anything about speech defects but simply because so many persons were afflicted The thing became a Frankenstein monster, and I had to give it up The treatment of speech cases is not for otolaryngologists, and I doubt very much whether it is for physicians at all It is a woman's job We have neither the patience nor the time I think that Dr Goldstein has really solved the problem and he certainly deserves the support not only of St Louis but also of the whole country This demonstration may give an erroneous impression There are thousands of cases of spastic speech defects that have nothing to do with general spastic conditions, also these patients impressed me as being mentally subnormal children There are innumerable bright persons who are stutterers, and thousands of orthopedic patients that have no speech defects

DR J A STUCKY Lexington, Ky Laryngologists have been using too many sprays and too much electricity in the larynx for the correction of speech defects, when the trouble was not there I should like to ask the author about one point in which I am much interested, and that is about the endocrine insufficiency What test did he make to determine this? My experience has been that we usually find hypopituitary and hypothyroid conditions but I am not satisfied with the tests I am making

DR. CHARLES G STIVERS, Los Angeles Not knowing anything about endocrinology, but having in my office an endocrinologist I turn these patients over to him and he gives them proper examination and treatment We have in this series two or three cases of endocrine dysfunction, and they are hypothyroid and hypopituitary cases I limited my statements about speech to the fact that speech production proceeded from stored muscle memories I did not say that speech began with the motor areas I said that one can move a muscle only if one has an inherent muscle memory which has been stored in the brain at some previous time A clearing up of most of the questions will be found in the paper itself which I did not read The paper itself is an academic discussion of the need for education of physicians and others who are to take up the work This film is a practical demonstration of the application I heartily agree with what Dr Goldstein said In the whole treatment of the spastic child I refer to the child who has other expressions of spasticity—not the spastic stutterer, which is a purely central manifestation The case is first approached by the orthopedic surgeon to make a diagnosis and apply corrective treatment—operations surgical dressings braces, etc—and to get the child into proper condition in which it can be given these exercises for the building up of muscle tone One of the best results we obtain in the treatment of the mouth and throat is the disappearance of the drooling This disappears when we build up the tonicity of the mouth muscles The work is so new and has gone on such a short time that we are not able to state definitely what we can do except with the vowels We have worked very little with the consonants, because the spastic cases tend to overact and we do not wish to pursue any line of treatment or exercise that would call for any more exercise of the muscles than is absolutely necessary The speech defect specialist is not only an otologist He also needs training in otolaryngology and ophthalmology, because speech may be both written and heard There is also a lot of psychology and neuropsychiatry and pediatrics, as well as study of how to produce articulation that can be interpreted by others and there one has the problem of knowing something about pedagogy I am perfectly willing to have young women of the right personality and manner to do the training and merely act as adviser leaving this active treatment work to the young women themselves

---

IS DEATH IN HIGH INTESTINAL OBSTRUCTION DUE TO LIVER INSUFFICIENCY?*

AXEL WERELIUS, M D
CHICAGO

Death in acute intestinal obstruction is almost generally conceded to be due to a toxemia derived from absorption of toxic products accumulated in the intestine above the obstruction The higher the obstruction, the greater the supposed toxicity, and the more rapid the fatal issue In order to examine this toxic material, segments in various parts of the intestine have been tied or sectioned off The results are practically the same as in ordinary obstruction

If the duodenum in a dog is ligated, or sectioned above and below, the animal dies in from twenty-four to forty-eight hours For several hours subsequent to the operation (sometimes twenty-four hours) the animal shows nothing abnormal, then the symptoms are ushered in rather suddenly with signs of increasing weakness and extreme sluggishness There is no restlessness, no irritability, no convulsions The animal lies down and refuses to come when called It does not seem to suffer As a rule, after twenty-four hours the temperature becomes subnormal with increased pulse and respiratory rate Very rarely is there any vomiting and then only after something has been eaten Constipation is complete The outstanding feature is a progressive asthenia

Death then occurs very rapidly and, as above, is thought to be due to absorption of highly toxic products in the loop of the duodenum If this were the true explanation, there would be some excuse for reasoning that if these toxic products would be drained out of the loop of the duodenum, the life of the animal, if not saved would at least be somewhat prolonged or, in other words, death would be delayed However, in

* From the South Shore Hospital Laboratory
* Read before the Section on Obstetrics Gynecology and Abdominal Surgery at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

thirty dogs, the loop was drained, and all died within the same period of time with the same symptomatic phenomena as do dogs with undrained loops

These experiments of draining the loop, if not disproving the presence of a toxemia, at least throw great doubt on absorption of toxic products from the loop as the cause of death It is doubtful whether very much, if any, absorption takes place in this region of the intestinal canal It is probably more of a receptor of only partly digested food products not ready for absorption until farther down the intestine after having been acted on by the bile and pancreatic juice In other words there is really not much need for absorption in this area

In obstruction farther down, absorption does of course take place, but, at any event, the presence of toxic substances in the blood in cases of obstruction has yet to be demonstrated In four normal dogs intravenous injection of from 10 to 20 c c of blood taken from bowel-obstructed moribund dogs showed no untoward symptoms whatever Toxemia has been produced by intravenous injection of the contents of an obstructed intestine, and the result in this case has been used in favor of the toxic absorption theory Undoubtedly the intravenous injection of normal bowel contents will also cause a toxemia

It is suggested that most of the offending toxin is absorbed from the cells of the mucosa of the obstructed loop If this supposition is correct, it would explain the inefficacy of draining the obstructed loops Extract from mucosa of these loops, injected intravenously into normal dogs, should then obviously reproduce the supposed toxemia in bowel-obstructed animals In three dogs, however, such extracts, injected intravenously, caused not the slightest disturbance Toxin in sufficient amount to kill the animal is not absorbed from the cells before gangrene has taken place, as the animal can be saved by operation in this period

The deadly damage must occur apparently, in the period of gangrene, which would then be a necessity for systemic dissemination of the deadly toxin That, however, is not so, since animals with drained loops that die with identical symptoms show no sign of gangrene or in fact, any other pathologic change Furthermore, absorption from mucosa cells is hardly possible, coffer-dammed as they are either by a bowel wall with complete vascular stasis or a bowel wall disorganized by gangrene

Ellis,[1] who reviews the entire literature of obstruction research, asserts that he has isolated a toxin from the intestinal contents and from the mucosa of the obstructed loop The toxin injected intravenously in dogs with no intestinal obstruction reproduces the clinical symptoms of obstruction, which Ellis says are vomiting, retching, diarrhea and tenesmus I have never seen diarrhea as a clinical symptom of obstruction either in men or in dogs Constipation, on the other hand, is a constant and universally observed symptom

The toxin described by Ellis was isolated from the mucosa of the obstructed loop As the toxin was taken after, or shortly before, death, it was obtained from an abnormal pregangrenous or gangrenous mucosa

Ellis stated that extract from nonobstructed intestine, that is, from normal intestinal mucosa, did not cause disturbance such as was caused by extract from obstructed intestine Extracts from normal and abnormal, especially gangrenous, tissues would not be likely to have similar effects Extracts from gangrenous intestine farther down, or from other gangrenous tissues, should be used as a control I would not be the least surprised if injection of such extracts would cause clinical and pathologic manifestations simulating those caused by the toxin described by Ellis

It has been asserted also that the toxin is bacterial and that the action of bacteria on necrotic tissue is the main factor in these deaths That bacterial activity plays a deciding role in acute intestinal obstruction seems exceedingly doubtful because death comes on rapidly in high obstruction in a region practically void of bacteria, and death comes on much more slowly in obstruction of the lower intestine, teeming as it is with a multitude of various organisms If the action of bacteria was a determining factor, the reverse ought to be true

Dragstedt[2] and his co-workers who advocate this theory, washed the loops with either alcohol or compound solution of cresol, aiming to destroy bacteria present Such treatment should, of course, be most effective in the duodenum almost void as it is of bacteria In fact, duodenal loops with both ends open caused no trouble whatsoever in some of the animals, showing conclusively how harmless or nonpathogenic the organisms must be in this region In spite of this favorable condition for antibacterial treatment, the animals died in about the same period as did those with unwashed loops, that is, in shorter time than in any other region of the intestine—a peculiar result, indeed, if bacteria were playing an important role

To defend the rather disappointing results, Dragstedt and his co-workers suggested that in this high region of the intestine the secretion greatly overbalanced the absorption This reasoning would fit splendidly to the results in experiments on a lower part of the intestine when all the animals died from rupture of the intestine, but it certainly does not explain the results in experiments on the duodenum when only half of the animals show a rupture at death

Lower down in the intestine by washing the loops with ether, life was prolonged not by interference with bacteria, but by delaying overdistention and consequent rupture Here all fatalities were caused by rupture of the intestine The washing of loops with ether delayed overdistention, by damaging the secreting cells of the mucosa, inhibiting, or at least interfering with, cell function Hence there was less secretion and delayed rupture and death

In some of the animals, undoubtedly, the cells were permanently destroyed Consequently no overdistention took place, and the animal lived indefinitely

Dragstedt and his co-workers state that bacterial activity plus necrotic tissue, or the absorption of toxic products resulting from the action of putrefactive bacteria on necrotic tissue, is the important factor in these deaths This, however, I decidedly dispute

Dragstedt asserted that necrosis of mucosa favored absorption In these loops, not only the mucosa but also the entire intestinal wall was necrotic or threatened to become so As necrosis is a direct result of complete stasis how could stoppage of circulation possibly favor absorption? In our drained loops, there was absolutely no necrosis, in fact, the intestine was per-

1 Ellis J W Cause of Death in High Intestinal Obstruction Ann Surg 75 429 (April) 1922 abstr J A M A 78 1665 (May 27) 1922

2 Dragstedt C A Cannon P R and Dragstedt, L R Intestinal Obstruction Study of Influence of Bacterial Flora on Toxemia of Acute Obstruction J Infect Dis 27 139 (Aug) 1920

feebly normal macroscopically and microscopically, still the same rapid deaths occurred

Some years ago I performed the necropsy on an infant, aged 3 days, that died from a complete stenosis in the lower duodenum. Except for this anomaly, the examination was entirely negative. The structure of the duodenum was normal. There was no sign of necrosis and I doubt whether there were any bacteria; at least there was no visible evidence of their activity.

On practically all Dragsted's experiments, an end to end anastomosis was made behind the loop, reestablishing the continuity of the intestine, thus doing away with the condition for which the research was done, namely, intestinal obstruction. If one studies obstruction, one must obviously deal with an actual obstruction. An isolated loop with continuity of the intestine established beyond is not an obstruction. In such a case with an isolated segment, we remove the most important factor, the interference with peristalsis. Without such interference we have no real obstruction, and conclusions drawn from the work cannot but be erroneous.

Drained or undrained duodenal loops give, as we have seen, exactly similar results, but in draining it was possible to make the interesting and important observation that in about twenty-four hours the bile secretion completely stopped and was replaced by a clear mucoid or, at times, a reddish fluid. In every instance the test for bile was negative. The cessation of bile secretion heralded the onset of untoward symptoms, and from that time on the animal rapidly lost ground, and the fatal issue was not long delayed.

The stoppage of bile was of the gravest possible prognostic significance in every one of the thirty-three animals used. In eight of the animals, bile was drained directly from the gallbladder, and in the others it was drained through the duodenum. Stoppage of bile meant death. It is seemingly a pathognomonic prognostic sign in high obstruction.

What did stoppage of bile secretion signify? Would it not be permissible to suspect that with the cessation of bile secretion all the other functions of the liver were suspended simultaneously? It is very unlikely that the liver just ceased the manufacturing of bile and that its other functions continued undisturbed.

The stoppage of bile rather indicated grave intrahepatic disturbances with possibly a complete standstill of the entire liver activity, in other words, a hepatic insufficiency or a condition that might be termed "ahepatism." Then death would be due to hepatic insufficiency. It is not impossible that other unexplainable deaths following upper abdominal operations might be traced to the same source.

In connection with the stoppage of bile and the suspected hepatic insufficiency it is interesting and rather confirmatory of this work to read statements from Dr. W. J. Mayo[3] and Dr. Crile[4].

Crile, in a paper on gallbladder surgery says: "If it is noted that the bile is becoming more scanty in amount and paler in color, the prognosis becomes correspondingly grave." He observed this distinctly in one patient who died.

Mayo says: "I venture to predict that the next few years will bring forth productive research demonstrating that the causes of the changes in vital organs which lead to death do not primarily originate in the nervous system, heart, lungs or kidneys but are the results of a hepatic insufficiency."

What, then, would cause the hepatic insufficiency? Would the tying or sectioning of the intestine cause a reflex inhibition of liver function? No, because anastomosis of the loop into neighboring intestine with gastro-enterostomy saves the animal.

Is a substance (hormone) secreted in this part of the intestine the absorption of which is required to stimulate hepatic activity? No. Resection of this part of the intestine is compatible with life.

Is it the simultaneous loss of bile and pancreatic secretion? No. Resection of the duct-bearing area of the pancreas and the biliary fistula do not cause rapid death.

Is death due to interference with peristalsis? At the root of the whole situation is of course the mechanical obstruction itself. This is one fact we cannot dispute. The obstruction interferes mostly with peristalsis, which is absolutely essential to life, possibly the greater the amount of nonperistaltic intestine, the graver is the danger.

In high obstruction, more intestine is nonperistaltic, therefore the danger is greater. When the entire intestine is nonperistaltic death is not far off, and even in the lowest obstruction death is preceded by aperistalsis.

By the aid of the fluoroscope, peristalsis is seen at first to be very active in the occluded loop. Later peristalsis becomes less marked and stops completely in from ten to twenty hours. This cessation of peristalsis precedes the stoppage of bile, as a rule by several hours. It is very possible that the liver needs this peristalsis as a reflex stimulus for its continued activity. Undoubtedly the entire gastro-intestinal system, with the liver and pancreas is entirely dependent on these muscular waves for continued functions.

Peristalsis below the obstruction seems to stop almost at once. One observes only for some time spastic contractions here and there. Bismuth injected below the obstruction moves very little or, usually, not at all, showing complete aperistalsis.

Injection of the rectum in late cases shows no peristalsis. In fact aperistalsis precedes death in all cases of obstruction.

Proximal to the obstruction we have noticed a to-and-fro peristalsis covering about 4 or 5 cm. and completing its cycle in about three minutes. A real antiperistalsis was never seen.

Seemingly the duration of life after intestinal obstruction bears a direct relation to the amount of intestine rendered nonperistaltic. In low obstruction, for instance, death comes on more slowly because there is only a small amount of intestine made inactive, that is less intestine is nonperistaltic. Death is preceded by stoppage of peristalsis of the rest of the intestine. At first the intestine becomes paretic from overdistention, then paralysis sets in.

If the intestine is drained proximal to the obstruction before paralysis has become complete and the paralyzing distention is prevented, peristalsis is again established and life is saved because a sufficient amount of intestine is again made active. If the drainage is low enough, life may be prolonged indefinitely.

The danger of overdistention is a real one in that it causes paralysis of the peristaltic or active intestine proximal to the obstruction thus rendering the entire

4 Crile, G. W.: Technic of Gall Bladder Surgery in Presence of Jaundice, Surg. Gynec. & Obst. 33: 469 (Nov.) 1921.

intestine nonperistaltic The Mayos especially recognized this, and in all cases in which the intestine had been subjected to marked surgical insult they averted the dangerous acute dilatation of the bowel by prophylactically instituting an outlet for the distending gases

From these observations it seems possible that the liver activity might be dependent on peristaltic waves traveling across the upper bowel, because stoppage of bile is always preceded by cessation of peristalsis If a dog with intestinal obstruction is operated on soon after bile secretion has ceased and the ligatures are loosened, the bile soon reappears, probably with the reestablished peristalsis This we demonstrated in two animals It might be possible that cessation of peristalsis causes inhibition of liver function, and death in high obstruction would then be due to liver insufficiency

CONCLUSIONS

It is doubtful whether death in intestinal obstruction is due to absorption of toxic products from obstructed intestinal contents or from its mucosa

Bacteria do not play any special role in the cause of deaths from obstruction unless rupture takes place, when the bacteria cause peritonitis

In all drained duodenal loops, bile secretion stops before death

It is possible that with the cessation of bile secretions all the other functions of the liver stop simultaneously (liver insufficiency)

Acute dilatation of the active peristaltic intestine proximal to the obstruction is the primary danger in acute obstruction of the intestine

Peristalsis stops before cessation of bile secretion

Death is always preceded by complete aperistalsis

It is possible that the amount of intestine rendered nonperistaltic bears a direct relation to the duration of life after the obstruction

EXPERIMENTAL WORK

Some of the observations recorded were made years ago when Dr James Moorhead and I did extensive research work on the duodenum for Dr S A Matthews at the University of Chicago

The present work was done under the most favorable conditions possible, as it was done in one of the operating rooms at South Shore Hospital with the assistance of interns and nurses

Sixty-five animals were used Twenty-seven animals with obstruction of part of, or entire, duodenum with drain, nine animals with obstruction of part of, or entire, duodenum without drain, eight animals with separate drain in the gallbladder, three animals with obstruction of the duodenum and jejunum with drain, five animals with obstruction of the duodenum and jejunum without drain, three animals with obstruction in the midgut, three animals with obstruction at the ileocecal valve, three dogs injected with mucosa extract and four dogs injected with blood from obstructed dogs

The laboratory examinations, by O Olson, included urinalysis observation of temperature changes, leukocyte count blood sugar determination blood urea determination, carbon dioxid combining power of blood plasma and tissue examinations Roentgenologic examinations included fluoroscopy and radiography

On a series of ten dogs with obstruction of entire duodenum with drain, the foregoing laboratory examinations were made The rectal temperature invariably fell from an average of 102 F before operation to an average of from 96 to 97 F twenty-four hours after obstruction

Urinalysis revealed albuminuria after operation, and an uncertain reduction of Fehling's solution in some cases

Other laboratory findings were a moderate leukocytosis averaging 20 000 after twenty-four hours, in most instances decreased blood sugar varying from 10 to 80 per cent of the original amount, an insignificant reduction in the carbon dioxid combining power of the blood plasma, and an invariable increase in blood urea

Tissue examinations revealed a normal mucosa in the obstructed loop with drain The liver invariably showed a congestion Other organs were normal

The decrease in blood sugar may be explained in the dysfunction of the liver As the liver is the great reservoir of carbohydrates, its dysfunction resulted in an inability to transform the glycogen into glucose, with a consequent decrease in blood sugar

The increase in blood urea may apparently contradict the theory of hepatic insufficiency It is asserted that in acute yellow atrophy there is an increased ammonia content and a decreased urea content in the blood The increase of ammonia is considered to be due to accumulation, as the liver is not able to convert it to urea

Recent investigation has shown however, that the liver is not the only organ concerned in the production of urea as a nitrogenous end product, many other tissues of the body are able to perform this function Is it not reasonable to suppose, therefore that an increased ammonia formation would be taken care of by these tissues in the absence of liver function, with a consequent increased blood urea content?

In a case of acute yellow atrophy, which diagnosis was confirmed by postmortem findings, repeated blood examinations were made and a progressively increasing blood urea was observed the percentage increase corresponding very favorably with our figures

ABSTRACT OF DISCUSSION

DR BARNEY BROOKS St Louis Dr Werelius is familiar with the literature, and is therefore familiar with the fact that some of the conclusions he reached are in absolute contradiction to some which I published a number of years ago I will not take time in discussing points he made with which I am in entire accord but will call attention to a few facts which I do not believe are in strict accord with one of the conclusions which he has reached An experimental animal will die from intestinal obstruction, whether the loop be high whether the loop be low whether it be isolated from the intestinal tract so is not to interfere with the normal continuity of the intestinal tract or whether the normal continuity is interfered with There accumulates within the lumen a toxic substance which can be isolated and which injected into a normal dog, causes death This toxic substance cannot be recovered from the normal intestine It is possible to produce an experimental obstruction in such a manner that the animal may live for a month and the loop of obstructed bowel may contain many hundred times the lethal dose necessary to kill this animal, without that animal showing symptoms If, however, this loop of obstructed intestine has its mucosa damaged, the animal succumbs rapidly I feel therefore that we are forced to conclude that after intestinal obstruction symptoms and death are due to an intoxication But the thing I want to call your attention to particularly is that in order to have an animal show symptoms, the toxin must not only be produced but must be absorbed I regard Dr Werelius observations as an important contribution to the study of intestinal obstruction because he has brought forward the first evidence of any demonstrable explanation of how this toxin affects the body Dr Werelius has brought forward very suggestive evidence that death in intestinal obstruction is accompanied by hepatic insufficiency, and he asks the question Is death due to hepatic insufficiency? and answers "Yes" I would go one step farther and say, Is the hepatic insufficiency due to an intoxication? and I would answer, 'Yes" All experimental work which has been done on intestinal obstruction teaches that the most important thing in the handling of a case of intestinal obstruction is early diagnosis and early surgical treatment When the lethal dose has been produced within the intestine and

has been absorbed into the circulation, there is at present no known method of saving life The toxin has already been introduced into the circulation It has already combined with the liver cell and produced an hepatic insufficiency

DR JAMES J MOORHEAD, Terre Haute, Ind I have long been engaged in a study of acute intestinal obstruction in the experimental animal So far as we were able to determine from a large number of experiments, bacterial activity, plus necrotic tissue or the absorption of toxic products resulting from the action of putrefactive bacteria on necrotic tissue is the important factor in the rapid death in simple closed intestinal loops An attempt to immunize the experimental animal against the poison contained in such loops proved futile It is well known that the functions of the liver are seriously disturbed by experiments such as those mentioned by Dr Werelius Some work now going on will probably give us more light on this important topic

DR THOMAS G ORR Kansas City Mo Drs Whipple, Brooks Stone and others have created quite a discussion in the last few years in regard to the cause of death and the toxic element in intestinal obstruction I have recently become interested in this subject by the study of three cases The first two were not cases of true intestinal obstructions but gastro enterostomies The other case was a straight case of intestinal obstruction The gastro enterostomies had very pronounced reactions, with rise in temperature, rapid pulse, dry tongue and everything that goes with that sort of condition Dr R L Haden made blood and urine studies in these cases Blood and urine chemistry disclosed that, instead of there being an acidosis, there was an alkalosis He further found that these patients had retention of chlorids, very much like that found in pneumonia He found, in addition, that they had a marked increase in the non-protein nitrogen The significance of the chlorid retention we are not able to determine at present Whipple of course thinks that the toxic substance in intestinal obstruction comes from a protein of some nature Whipple also thinks that there is a change in the kidney which prevents the elimination of chlorids We believe that the chlorids are retained in the tissues, as in pneumonia In these gastro-enterostomy cases there must have been a partial obstruction to the duodenum The symptoms lasted only a short time, and both patients recovered and did well after a few days I think there was some mechanical interference at the stoma, which produced symptoms very much like those of intestinal obstruction This may give some idea of the nature of the trouble that sometimes occurs in the convalescence after gastro enterostomy A few patients have reactions and others go on and have no more trouble than with the interval removal of an appendix I believe it quite probable that some very valuable therapeutic points may be found in the study of the blood chemistry of these cases That is, of course, one of our chief interests I should not be surprised if the liver is very markedly affected in these obstruction cases when there is such a toxic element absorbed as we know exists in the duodenum I should be surprised if all the parenchymatous organs were not involved very materially by this general intoxication

DR. AXEL WERELIUS, Chicago Dr Brooks makes a good objection He says that in draining the loop one cannot get all the toxin That is possible, as only a small amount may be required to kill the animal However, if that should be so let us trace the poison further In order to be absorbed, it must pass through the mucosa, and only a small amount is needed An extract of mucosa of the entire loop must surely contain enough of the toxin The intravenous injection of such an extract, however in normal dogs caused no disturbance whatsoever This surely speaks strongly against absorption from the lumen Furthermore, so far no one has ever isolated any toxic substance in the blood in intestinal obstruction in man or in animal Dr Moorhead says that gangrene of the mucosa favors absorption In these occluded loops not only mucosa but also entire bowel wall is necrotic As necrosis is a direct result of complete stasis, how could stoppage of circulation possibly favor absorption, and further, in drained loops in which animals die exactly the same, there is absolutely no pathologic change of the duodenum Consequently, gangrene of mucosa means nothing, one way or the other

RELATION OF ANESTHETIC TO PULMONARY ABSCESS FOLLOWING NOSE AND THROAT SURGERY*

C N CHIPMAN, M D
WASHINGTON, D C

During the last few years, there has been so much discussion about pulmonary abscess following nose and throat surgery, especially tonsillectomy, that many surgeons believe lung abscess to be the most important and dangerous complication that may occur It is my firm conviction that the rate of lung abscess per thousand nose and throat operations is no greater than it was twenty years ago In considering any complications following nose and throat surgery today, we must not loose sight of the fact that tonsillectomy, in proportion to the total number of operations for all conditions, is far more frequent than ever before In some hospitals doing general surgery, about 30 per cent of the total number of operations each year are for nose and throat conditions

An examination of thousands of cases in which anesthetics are given in nose and throat surgery, especially tonsillectomy, reveals that nose and throat operations are performed not only by the nose and throat specialist but also by the general surgeon and by the general physician who makes no claim of any specialty Therefore, we should expect to have more complications

Only during the last few years has it been admitted that an abscess may and does occur in the lung as readily as in any other part of the body Richardson[1] as late as 1912, reported the first lung abscess following tonsillectomy Osler reported lobar pneumonia as a complication Abscess of the lung occurred clinically in seventy-six among 12,030 cases (0 63 per cent), and at necropsy, it was found in twenty-eight of 1,294 cases (2 1 per cent), a frequency which can by no means be ignored, showing that only about 25 per cent of the abscesses were recognized before necropsy During the recent influenza epidemic, lung abscess was a frequent complication During the last four months two lung abscesses have been reported to me, one following an operation for intestinal obstruction, the other following an operation for chronic appendicitis

Dr Harry Wessler, associate roentgenologist to Mount Sinai Hospital, New York, in 1920 reported twenty-eight cases of lung abscess and gangrene, eight of which followed tonsillectomy

Following a nose and throat operation, with such symptoms as pain in the lung, cough, chills, irregular temperature and foul sputum, the diagnosis of lung abscess should be easy, in fact, it is hard to see how any one can consider any other diagnosis If there is any doubt about the condition, the roentgen ray and fluoroscopic examination will clearly reveal the abscess

CASES REPORTED

Eleven surgeons, whom I interviewed, have treated twenty-four lung abscesses Twenty followed tonsillectomy, two followed submucous resection of the septum, and two followed frontal sinus operation Tewksbury has had a total of thirty-five cases Ten cases were untreated (that is, artificial pneumothorax

* Read before the Section on Miscellaneous Topics at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Richardson C W Washington M Ann May 1912

was not produced), six patients died, three recovered, and one was lost track of, so that the results could not be reported Among twenty-five patients in whom Tewksbury compressed the lung, twenty were cured, one improved, and four died Twenty-one lesions were in the right lung near the hilum, four were in the left lung near the hilum Tewksbury informs me that in producing artificial pneumothorax, he now *obtains much better results by injecting a smaller volume* of gas at each sitting than he first used

Kendlemen[2] reports two cases Lewis[3] states that he has had seven clinical cases Thomas Klein reports one case Fisher and Cohen[4] reported seventy-three cases last year, five of the patients were admitted to their services after operation had been performed elsewhere The other case reports had been compiled by Bossin, nineteen cases, Manges, ten cases, Frank, eighteen cases, Tewksbury fifteen cases, Dodd, two cases, J W Williams, one, and Clendenning, one Porter reports two cases of lung abscess following local anesthesia

The total number of cases reported above is 145, but twenty-one cases have been reported both by Tewksbury and the operator, so that this leaves a net total of 124 patients having pulmonary abscess following nose and throat operations In thirty-three cases the right lung was involved twenty-seven times, and the left lung six times The right lung is involved much more frequently than the left because the right lung is larger, and because the right bronchus is larger and straighter than the left, so that the entrance for the infected material in the right lung is more direct and easier than in the left lung

My paper had been completed when Moore[5] published an analysis of 202 cases of pulmonary abscess following operative work about the upper respiratory passages I refer to his analysis because the conclusions are very similar to mine He reports the anesthetic used as ether, 151 *times local, thirty-nine times*, and gas, eight times When patients were treated in the upright position, ether was used twenty-nine times and local anesthesia, thirty-nine times In about 70 per cent of the cases, the right lung contained the abscess Suction was not used in ninety-three cases, this, to me, seems inexcusable I infer from his reports that no one is attempting to sterilize the mouth, pharynx and tonsils Now that the ice is broken with a report of thirty-nine cases under local anesthesia, we may expect treatment to be more impartial and intelligent Allowing for duplications, we have about 300 cases in the two reports

DANGER OF LOCAL ANESTHESIA

Local anesthesia per se, especially when cocain is used is more likely than nitrous oxid-oxygen or ether anesthesia to cause the sudden death of the patient during the operation The committee on the advantages and disadvantages of the various local anesthetics,[6] composed of Mayer Skillern and Sonnenschein, report twenty immediate deaths from local anesthesia, two from nose operations, and eighteen from throat operations Such a large number of deaths from local anesthesia, for what many consider minor operations, cannot be lightly passed

French[7] reports that a girl, aged 12 years, met death in forty seconds from a hypodermic injection of 12 drops of a 4 per cent solution of cocain

Gibson[8] reports a case of poisoning occurring after two applications of a 2 per cent solution of cocain to the throat and tonsils Last summer a New York daily *newspaper continued the news item* "Mrs H, a young woman 28 years of age, died on the operating table during an operation for removal of the tonsils under local anesthesia from uremic convulsions" The probable cause of the convulsions and death in the foregoing case was cocain poisoning

A large number of sudden deaths have been reported from injection of cocain solution in the urethra to pass sounds or cut a stricture, and death even has resulted from a few drops of 5 per cent solution of cocain, dropped in the eye for some minor operation

With these facts undisputed, many still assert that local anesthesia is safer than ether or nitrous oxid-oxygen anesthesia The literature nowhere contains any such number of sudden deaths from ether or nitrous-oxygen anesthesia, during nose and throat operations A live patient with lung complications following ether anesthesia is better than a dead patient following cocain anesthesia

TYPE OF ETHER ANESTHESIA TO BE USED

It is admitted by those advocating local anesthesia that ether anesthesia per se does not cause pulmonary abscess, also it is well known that lung complications occur most frequently when ether anesthesia is used In explanation, there are a number of conditions to be considered The first is deep ether anesthesia In nose and throat surgery, only light ether anesthesia is required, and yet one frequently sees the patient profoundly narcotized with the pupils widely dilated Such a condition makes it easy for blood and infected material to be carried into the lungs, especially the right lung, by inspiration When the reflexes are completely abolished, there is nothing to prevent fluids from entering the larynx and lungs, and nothing to warn one that they are doing so With the reflexes not abolished, when fluid enters the larynx, the patient will attempt to expel it In other words, why do we cough when not anesthetized? Because there is something in the bronchi which we wish to expel We know that if a body is removed from the water shortly after drowning the lungs will not contain water, on the contrary, if the body is placed in the water after death, the lungs will contain water, because there were no reflexes to protect them

Another condition that invites aspiration under deep anesthesia is having the head level with the body or elevated, so that there is nothing to prevent blood and mucus from entering the larynx During a tonsil operation when the patient is wearing a tracheotomy tube, if the head is not lowered and blood is allowed to collect in the pharynx, some of the blood will be expelled through the tracheotomy tube

CONDITIONS THAT MAY CAUSE LUNG ABSCESS

Those methods of operating that unduly tear and crush the tonsils, thus filling the pharynx with caseous material, and not infrequently liquid pus, aid in producing lung abscess Also, it is admitted by all that the

mouth and pharynx comprise one of the most extensively infected fields for an operation, and yet but few make any attempt to cleanse and sterilize the teeth and tonsil region There was an epidemic of lung abscess following the recent influenza epidemic There were more lung abscesses during 1919 than during several years preceding the influenza epidemic At that time, the hemolytic streptococcus was the prevailing organism found in the tonsils Nichols and Bryan[9] recovered hemolytic streptococci from the crypts of 75 per cent of 100 pairs of extirpated tonsils

Cajigas,[10] in 1919, found hemolytic streptococci present before operation in 170 out of 200 cases, or in the tonsils of 85 per cent of the patients examined Many observers have found hemolytic streptococci present in normal throats in from 4 to 30 per cent of patients examined It is possible that, if more attention were given to streptococci infection of the tonsils, the result would be a smaller number of lung abscesses

ORIGIN OF LUNG ABSCESS

Is lung abscess due to aspiration or embolism? It is an undisputed fact that many lung abscesses, both in operative and nonoperative conditions of various parts of the body are of embolic origin It would be very convenient if we could feel as sure as Fisher and Cohen that lung abscess following nose and throat surgery is of embolic origin, for then it would make little difference if local or any one of the various forms of general anesthesia should be used It is difficult to see how the cause can frequently be other than aspiration, when we consider that, out of thirty-three cases, the right lung was involved near the hilum twenty-seven times Embolic abscess is most frequently found near the edges, rather than the center of the lung When all facts are taken into consideration, we must conclude that lung abscess is caused both by aspiration and by the infective embolus, carried to the lung by the blood stream or lymphatic system

It has been my aim in this brief paper not to try to disprove the occurrence of lung abscess, but rather to present evidence that lung abscess does occur, and far too frequently For this condition, the anesthetist, the surgeon and the methods of procedure used, rather than the anesthetic, are to blame

HOW TO PREVENT LUNG ABSCESS

1 A patient should not be operated on within seven days after an attack of tonsillitis, or when there is acute bronchitis or a fever from any cause

2 The patient should be in the hospital at least six hours, or better, twenty-four hours before operation

3 The mouth and teeth should be thoroughly cleansed, before the operation, with some antiseptic solution

4 Only light anesthesia should be used

5 The head should always be down, and by suction the pharynx kept free from infective material

6 The tonsils and pharynx should be painted before operation with 50 per cent tincture of iodin, also the cavity should be swabbed with iodin after removal of tonsils

7 Bleeding should be stopped at once by suture or ligature rather than prolonged sponging thus reducing the anesthesia and obtaining a dry pharynx

8 In all nose and sinus operations, a posterior nasal plug should be used

9 The patient should be returned to his room on his side, with the head down

10 After operation, the foot of the bed should be elevated until the patient has fully reacted, unless the patient has high blood pressure

11 Last, but not least, nose and throat operations should receive the same care and skill by both the surgeon and the anesthetist as are given to an abdominal operation, and there will be fewer lung abscesses to report

---

ABSTRACT OF DISCUSSION

DR A H MILLER Providence, R I The most common cause of lung abscess in general is pneumonia, and lung abscess frequently follows postoperative bronchitis or pneumonia For these reasons we cannot consider postoperative lung abscess separately from other pulmonary complications In the pulmonary complications occurring in the lower lobes and following operations on the upper part of the abdomen the infection may be carried through the lymphatics In multiple postoperative complications the condition may be embolic But in the majority of the cases we believe that the pulmonary complications are of inspiratory origin, and as a result of inspiration of infectious material either bronchitis, pneumonia or abscess may develop We find these complications following every type of anesthetic and any class of operation There are conditions which favor the occurrence of these complications One surgeon reports a series of lung abscesses during a limited period while other surgeons will have no such cases In searching for the cause of these conditions we are concerned with the depth of anesthesia the position of the patient, the preparation for the operation and the use of suction There is a difference of opinion as to the value of suction in throat surgery I note that as time goes on surgeons use the suction apparatus less and less The reason is that with the improvements in operative technic they need it less and less A factor of the greatest importance is the depth of the anesthesia With profound anesthesia protective reflexes are abolished and the respiratory passages are laid open for the entrance of infectious material With a light depth of anesthesia, postoperative pulmonary complications very rarely occur Another important factor is the manipulation of the jaw I believe that many pulmonary complications have been due to the practice of pulling the jaw forward when the patient attempted to vomit Drawing the jaw and the tongue forward opens the respiratory passages for the entrance of foreign material I believe that these two factors, profound anesthesia, and manipulation of the jaw are responsible for most of the postoperative lung complications

DR R S ADAMS San Antonio Texas I am sure that after having heard these two papers, and Dr Miller's discussion, we can all be assured that the term anesthetic or ether pneumonia will soon be a thing of the past Chilling of the body surface is one of the most important factors in this connection The average patient is accustomed to heavy sleeping garments He is given a thin nightshirt that does not cover the upper part of the chest, and is repeatedly exposed for preoperative preparation, examinations etc He is then transported through a drafty elevator shaft or chilly hall to the operating room and if in addition he is placed on an operating table that is not kept warm and cold, moist packs are allowed to remain in the abdomen and an excess of mucus accumulates we can readily see why 2 per cent of all patients operated on develop these complications Henle in 1901 made an exhaustive report on the lung complications following 1 786 abdominal operations Local anesthesia was used extensively and he noted an increased morbidity but lessened mortality In patients suffering from asthma chronic bronchitis or emphysema or in those in whom infection was coexistent the morbidity and mortality were increased Animals were anesthetized with ether and soaked with cool water the control animals were anesthetized and

9 Nichols H J and Bryan J H The Tonsils as Foci of Infection in Streptococcus Hemolyticus Carriers J A M A 71 1813 (Nov 16) 1918

10 Cajigas, Thomas Bull George Washington Univ October, 1920

placed on vacuum pillows The lungs of the chilled animals showed a general hyperemia, swelling and desquamation of the alveolar epithelium, and when sputum containing the pneumococcus was placed in the trachea, those chilled all developed pneumonia, while the reverse as to lung findings and pneumonia was found in the control series Even at this early date, Henle mentioned the possibility of emboli from the operative field traversing the lymphatics and veins to the lungs Whipple thinks that the aspiration into the bronchioles of mucus which had become laden with germs from the mouth and tonsils was the most frequent cause of postoperative pneumonia, and considered the Type IV pneumococcus the usual offending organism Whipple emphasized the value of the roentgen ray in arriving at an early diagnosis of lung complication The work of Cutler and Hunt and more recently of Cutler, elaborating on the embolic theory of pneumonia, is attractive I should be inclined to believe that those cases of pneumonia coming on within forty-eight hours after the operation were usually of the aspiration type, while those occurring later could more properly be classed as embolic Lemon, in reporting on eighty-one cases of lung abscess, found that seventeen were postoperative and of these seventeen, twelve followed operations on the nose and throat I believe, with Dr Chipman, that the method of anesthesia is of prime importance in tonsil surgery, as advantage should be taken of the electric motor vapor and suction apparatus, thus permitting of a light, even plane of anesthesia, most of the mucus and blood being removed, thus minimizing the dangers of aspiration When the face mask is reapplied several times in nose and throat surgery, an uneven plane of anesthesia ensues, causing greater danger of aspiration I hope that the time is not far distant when every one connected with the operation will realize that the anesthetic and method of anesthesia comprise only one of many factors bearing on postoperative pneumonia and lung abscess

DR FRANCES E HAINES, Chicago I agree with practically everything that has been said I have never seen pulmonary abscess or pneumonia following nose and throat surgery The Chicago men whom I have consulted never had a pulmonary abscess They all use the ether vaporizing and suction machine sometimes in clinic cases, but not much in private cases because they operate rapidly They all agree that pulmonary abscess is due usually to inspiration of septic or foreign material, in practically all cases, therefore, it is due to carelessness The semirecumbent position is never used by these men dorsal position for general anesthesia, and sitting erect for local anesthesia Dr Shambaugh has an assistant turn the patient on the side immediately at the close of the operation Drs Pierce and Theobold emphasize that anesthesia should never be too deep or too light A light anesthesia should be employed Our ether patients are so lightly under the anesthetic that they attempt to crawl off the cart when returning to the room The outlook is hopeful, since the vast majority of cases are due to aspiration If the surgeon and anesthetist will watch and protect the larynx, pulmonary abscesses will result only rarely

DR EDWIN MCGINNIS, Chicago Cocain anesthesia is dangerous unless care is used Dr Chipman mentioned 2, 5 and 10 per cent solutions I use 20 per cent and sometimes the flake cocain I am in the habit of telling students that the weaker solution is the more dangerous in that the surgeon using a weaker solution of cocain thinks he is safe and does not take into consideration how much solution he uses The thing that does the anesthetic work is the cocain itself I had one unfortunate death from local anesthesia, and we never determined whether we injected the cocain or whether some complication caused death I do not use the suction apparatus in tonsillectomy I use the original Sluder tonsillotomes On one I had a catch put so that I could run it down and set it in any position I desired We very often have acute tonsillitis following nasal operations If I have a patient needing a tonsillectomy and a nose operation, the tonsillectomy is done first Dr Herb saw an experimental animal in which we had produced an acute pneumonia and acute nephritis The staphylococcus from skin infection or osteomyelitis will produce abscesses in the internal organs The cervical adenitis cases that break down, the few that we have been able to follow up bacteriologically, have been infections with *Streptococcus hemolyticus* From the work that we have done, it does not seem possible that a lung abscess could follow an operation on the nose unless we get a tonsillitis with the invasion of *Streptococcus hemolyticus* I also do bronchoscopic work It has always been our experience that in almost all the foreign body cases in which the object was not removed within a month or six weeks following the accident we got some purulent conditions in the lung in the region of the foreign body In the early days the foreign body cases were not diagnosed Often they were present in the lung six or eight years All of those patients had a lung abscess A woman had a tonsillectomy done in Indiana recently She warned the anesthetist that she had a pivot tooth On awaking her tooth was gone They decided that the tooth had been swept up and thrown out with the refuse Six weeks later she developed a cough and rales in the right side of her chest She went through various government hospitals, and finally it was decided to send her to Arizona for pulmonary tuberculosis Some one suggested that the roentgen ray be used They found the pivot tooth in the right bronchus She had an abscess cavity 2 inches in diameter, and the tooth was at the bottom of it Efforts to remove it failed During the night she had an attack of coughing, and the tooth came up with a large amount of mucus She made an uneventful recovery

DR LOGAN CLENDENING Kansas City, Mo This is the most important problem that the anesthetist has today I see on an average one case a week following nose and throat operations The anesthetist or the nose and throat man does not always know that his patient has developed a pulmonary abscess The symptoms develop as late as two weeks afterward The anesthetist or laryngologist hears that the patient has left the hospital, but has developed "a cold" or has influenza," and is under the care of a general practitioner, but not until two or three weeks later is the case definitely recognized as a lung abscess I am very much interested in the embolic or inspiratory origin of these things There is no question that there are embolic abscesses I have seen patients with abscesses of the cervical lymph glands develop a double femoral phlebitis, abscesses in both lungs and finally die We found at necropsy multiple abscesses in the lung pericarditis double pleural empyema and double femoral thrombophlebitis Embolic abscesses are usually of that kind They are multiple The ordinary abscess that follows tonsillectomy is of a different character It is usually single, in the lower lobe of the right lung I have had one experience which seems to me to demonstrate the fact that the origin is inspiratory We had a patient who on the second day after tonsillectomy had a temperature of 100 F and on the third day, 102 F with a patch of rales in the back The next day the temperature was normal The patient had coughed up in the night a clot about the size and shape of a small secondary bronchus She had inspired that septic blood, it had clotted in her bronchus, and in a short time would have infected it I believe that the origin of lung abscesses following throat operations is inspiratory in most cases It is the safest view to take, rather than to comfort oneself with the doctrine of an embolic origin As to prevention, all our efforts should go toward preventing those conditions which favor the inspiration of septic material I am not committed to the doctrine of accusing your favorite motor driven anesthesia apparatus, though I am still unconvinced that those machines are entirely innocent I believe that the depth of anesthesia is a most important factor, also the position of the patient, and all those other things that may have to do with the inspiration of septic material If we work on the basis of that doctrine we shall arrive at the nearest approximation to success in the prevention of these abscesses

DR E I MCKESSON Toledo, Ohio There can be no doubt that there is an embolic origin of pulmonary complica-

tions That there is the aspiratory cause of complications is also certain I want to call attention to one point In the administration of cocain or local anesthetics in tonsil work I believe most of the cases are injected We are constantly being surprised by the discovery of abscesses around the tonsil The introduction of the needle through this abscess, unintentionally, and then injecting the contents of the contaminated eye of the needle directly into the blood stream, is a possible cause of embolic abscesses

DR C N CHIPMAN, Washington, D C There is one thing that I cannot emphasize too strongly, that is the early diagnosis and treatment of these cases Tewksbury, to whom I referred, and who limits his work to the lungs has found that if these cases are obtained early and the lungs are compressed, from 80 to 90 per cent will be cured It is really appalling to see the number of men who make no attempt to cleanse or sterilize the mouth Patients come to the operating room with their teeth and mouth filthy We can at least have the teeth and mouth cleansed, and paint the tonsils and peritonsillar region with tincture of iodin before the operation and swab out the cavities with the same solution after the tonsils are removed I feel that if more attention is given to sterilization of the mouth we shall have fewer cases of lung abscess

SUPRARENAL GLAND IN ANESTHESIA*

J F CORBETT, M D
MINNEAPOLIS

It has been a common observation that certain patients do badly under ether anesthesia Especially is this true in cases of typhoid, in starvation in severe infections of all kinds, in late intestinal obstruction, in patients suffering from shock, and in persons who have either acute or chronic secondary anemia due to hemorrhage In addition, one hesitates to use ether in cases of exophthalmic goiter On the other hand, with nitrous oxid one can operate with comparative safety, and I believe that nitrous oxid has an advantage in my hands at least, over local infiltration Therefore I have attempted to analyze the underlying principles on which these statements have their foundation First of all these agents, nitrous oxid seems to do least harm Why it does least harm it is the purpose of this paper to explain from data collected for the purpose

From the list of diseases I have enumerated it would seem that, if something could be found in all of these conditions to be common, and if this something was also a result of prolonged etherization, a satisfactory explanation could be reached A research that I undertook at the University of Minnesota shows that there is one thing at least common to all of the conditions mentioned above This one thing is epinephrin exhaustion We have varying degrees of epinephrin loss in shock in hemorrhage, in typhoid, in fright, in starvation in infection and in prolonged etherization

Epinephrin exhaustion of the suprarenal glands comes alone through explosive output of epinephrin These explosive outpourings of epinephrin are clinically evident in certain forms of exophthalmic goiter although I do not possess absolute data as to the epinephrin content of the suprarenal glands in this condition Vasomotor balance is maintained ordinarily by minute amounts of epinephrin normally in the blood Intense vasoconstriction may be brought about by increased amounts of epinephrin in the blood stream

In hemorrhage, there is a relation between blood pressure, blood volume and vasoconstriction For example, I had a patient whose systolic blood pressure was 120, diastolic pressure, 70, hemoglobin, 45, and pulse rate, 140 This patient was in no apparent danger She was intensely white She was white because she had an intense vasoconstriction This patient was putting out large quantities of epinephrin to maintain the vasoconstriction The volume of blood was very small, but rapid pulse and vasoconstriction compensated for the circulation Had we allowed the patient to progress, even though no more bleeding occurred, she in all probability would have collapsed without apparent cause, when the epinephrin was exhausted and vasoconstriction failed Blood transfusion was performed, and the patient operated on under gas anesthesia At the conclusion of the transfusion the hemoglobin was 60 and the patient had received only 380 c c of blood, the systolic blood pressure was 120 and the diastolic blood pressure, 80 It is apparent that the blood volume was small At the end of twenty-four hours the systolic blood pressure was 100, diastolic 55 hemoglobin 44, but the face was more ruddy and vasoconstriction was less active I have repeatedly seen collapse in patients who after some time were not bleeding, but who had bled and maintained a balance until vasoconstriction failed In other words epinephrin exhaustion had occurred Those patients having compensation do not die until the compensating agent has been exhausted

No one seems to know what shock actually is The work of Malcomson and of Seelig and Lyon shows that a general vasoconstriction and reduction of blood volume occur Yandell Henderson tells us that shock is due to the escape of fluids through the vessel walls, and that these fluids are lost as in hemorrhage In shock, the circulation is compensated for just so long as vasoconstriction is maintained, and in some measure in proportion to that function When vasoconstriction does not compensate fall of blood pressure and, at length collapse occur Epinephrin maintains the vasoconstriction and more than the usual output is needed The residual reserve of epinephrin in the suprarenal glands is finally used up in traumatic shock, and when it is, death occurs

In a study of experimental and clinical shock, I was so impressed by the similarity in the pictures presented by victims of shock and animals from whom the suprarenal glands had been removed that I decided to make a study of the suprarenal gland With this purpose, I performed 350 animal experiments I made a study of the residual epinephrin in the suprarenal gland in animals subjected to various procedures or dying from various causes The epinephrin determinations were done according to the method of Elliot that is by means of physiologic standardization This method, when carefully controlled with standard epinephrin, is reliable As a result I found epinephrin to be exhausted in the list of cases in the accompanying table From these data one might be led to infer that etherization and not trauma, was responsible for the low epinephrin content of the glands in this series However I had the opportunity to examine the suprarenal glands from subjects of shock who had never been etherized In three such cases there was low epinephrin content, but not complete exhaustion I do not believe that epinephrin exhaustion is shock, but I believe that, when there is an exhaustion of that element, there is nothing with which shock can be con-

* Read before the Section on Miscellaneous Topics at the Seventy-Third Annual Session of the American Medical Association St Louis May 1922

trolled unless we increase blood volume by transfusion, and obviate the necessity of intense vasoconstriction This fact was further emphasized by the extreme epinephrin exhaustion following nerve stimulation Shock does not manifest itself after long continued nerve stimulation in animals having a low epinephrin content However, such animals go into shock almost immediately after the abdomen is opened with slight trauma That is, there is nothing left to combat shock

I further found that etherization alone greatly exhausted the suprarenal glands This was in some measure controlled by morphin, but not absolutely Nitrous oxid did not to so great a degree in itself cause epinephrin exhaustion I believe that the use of nitrous oxid is safe not in that it protects the nervous system from trauma, but in that it does not per se exhaust the suprarenal glands, and in that it removes the element of fright Nitrous oxid improperly given, and especially when not safeguarded by morphin and atropin, does exhause the suprarenal glands It is of interest here to state that we often got a blood pressure tracing similar to that obtained on vagus stimulation, when no atropin was used These experiments showed epinephrin exhaustion Scopolamin-morphin anesthesia also exhausts the glands

Fright is one of the greatest agents we have in epinephrin exhaustion I believe that it is for this reason that depletion of the epinephrin content in the suprarenal glands occurred in our animals with local anesthesia, in spite of the fact that all animals operated on were handled as gently and diplomatically as we would handle a patient in the hospital Most patients can go through local anesthesia operation without pain They may smile, but it has been my observation that after operation the facies changes The change in appearance suggests shock Further than this, I have seen shock follow operation with local anesthesia This usually develops some time after operation and, as Harris says, "the patient flattens out" I do not believe that ether is quite as dangerous as we are told For instance, I have performed about 200 operations on the injured arms and legs of soldiers These are long, tedious operations requiring from two to five and one half hours The work was done under ether In the service, there were no deaths, and in only one instance was there approach to a mild shock These persons were in good health except for the deformity, and had a good epinephrin content Had the epinephrin content of the same persons been depleted by some of the agents mentioned above, they would not have stood the ether so well

EPINEPHRIN CONTENT OF SUPPARENAL GLANDS

Condition	Epinephrin Content Per Cent
Normal instant death by magnesium sulphate	100 00
Infection, postmortem	0 03
Typhoid	0 03
Jaundice obstructive in vivo	0 80
Peptone*	0 15
Anaphylaxis*	0 36

Morphin ether operation five hours recovery in four hours content after twenty four hours	0 29
Morphin ether operation five hours recovery in four hours content after forty eight hours	0 40
Ether operation trauma recovery in four hours content after twenty four hours	0 26
Starvation (Elliot)	0 50

The figures in the table express the percentage of epinephrin obtained from the suprarenal glands of animals subjected to procedures as indicated The content of normal glands obtained from animals instantly killed with magnesium sulphate was taken as 100 per cent Each figure represents, in all but seven instances, ten or more experiments A star indicates the cases in which less than ten experiments were done

I am submitting a table for study and analysis I cannot detail all of the combinations and conclusions one might make, but should prefer to leave it with the reader for study and deduction It gives a physical explanation for many things we know to be true from clinical observation

ABSTRACT OF DISCUSSION

DR NETTIE KLEIN, Texarkana, Texas Dr Corbett did not give any one cause as producing shock, and while the causes will gradually increase in number we are still in the experimental stage as to the epinephrin content of the suprarenals under anesthesia and in shock The interrelation of the endocrines is so close that it is hardly possible to have a pathologic condition arising in one gland without some disturbance in the other gland Whenever an animal survived a longer time necropsy often disclosed hypertrophy of the accessory glands Compensating hypertrophy explains the variability of the time of survival in some cases when animals are subjected to partial or complete removal of the suprarenals In the diseases that Dr Corbett mentioned, we see the patients when they are in an extremely toxic state The endocrine system is depleted and the polyglandular picture is more evident than just simply the exhaustion of the suprarenals alone

DR ANSEL M CAINE New Orleans My knowledge is limited entirely to clinical experience One would think, after reading this paper and seeing the results as shown on the charts, that administering epinephrin chlorid in shock would, to a large extent give a patient a chance to recover There is a lot of truth in that If we administer saline solution or glucose to which from 10 to 15 minims of epinephrin chlorid has been added the patient will recover enough so that proctoclysis can be used and supply the necessary fluids, if the shock is due to loss of blood, or the patient can recover entirely on his reserve power Crile has shown that when he administered 1 50 000 epinephrin at the rate of 3 cc a minute over a long period of time, it did a great deal of good The blood pressure was maintained very well for a time, but it did not hold out But, as Dr Klein said, you cannot expect that the loss of epinephrin would be the only cause of shock and I am sure that Dr Corbett does not believe that it is the only cause of these constant symptoms, but by knowing the action of these internal secretions we can do good For that reason we always use epinephrin chlorid

DR J F CORBETT, Minneapolis I do not contend that shock is simply an exhaustion of the suprarenal There is, however abundant evidence to show that residual epinephrin is necessary to overcome shock The results of experiments

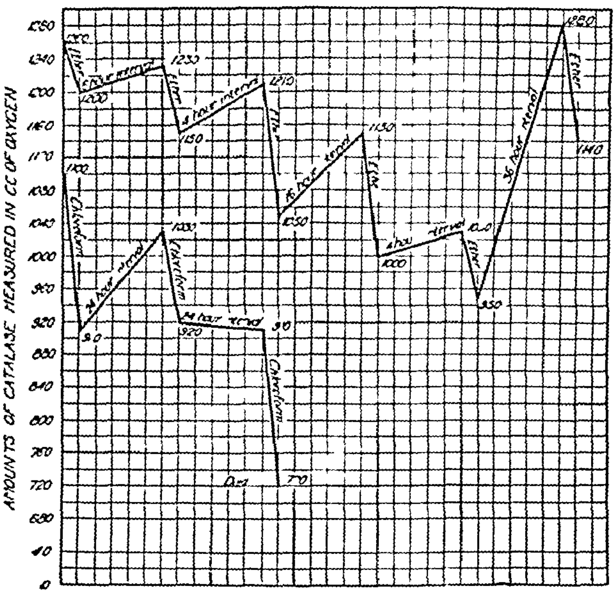
on animals by various investigators have been conflicting When we stop to consider that the question of accessory chromaffin glands has not been taken into consideration by many of these investigators, we have an explanation for the contradictory opinion I do not believe that epinephrin should be administered artificially in shock except for the purpose of tiding over temporarily some grave crisis The purpose of the discussion is to emphasize the conservation of epinephrin

EFFECT OF REPEATED ADMINISTRATION OF ANESTHETICS ON BLOOD CATALASE *

W E BURGE, Ph D
URBANA, ILL.

We had already found that anesthetics produce a decrease in catalase, an enzyme possessing the property of liberating oxygen from hydrogen peroxid, and accordingly suggested that this decrease in catalase with resulting diminution in oxidation might be responsible for anesthesia It was also found that a strong anesthetic such as chloroform, produced a much greater decrease in catalase than a weaker anesthetic, such as ether and that a rapidly acting anesthetic, such as nitrous oxid, decreased catalase more rapidly than a more slowly acting one

The object of the present investigation was to determine the effect of repeated administrations of anesthetics on the blood catalase The animals used were rabbits, and the anesthetics chloroform and ether Catalase determinations were made by adding 1 c c of the rabbit's blood, diluted 1 3 with 0 9 per cent sodium chlorid, to neutral hydrogen peroxid and the amount of oxygen liberated in ten minutes was taken as a measure of the catalase content of the blood Determinations were made immediately before and after fifteen minutes of anesthesia



Decrease in blood catalase brought about by fifteen minute intervals of ether and chloroform anesthesia with subsequent increase in catalase during the intervals between anesthesia

In all, twenty-four rabbits were used, twelve for chloroform and twelve for ether The results of two experiments, which are fairly typical, are given in the accompanying chart

It may be seen that the effect of the repeated administration of ether and chloroform was to lower the catalase content more and more after each successive administration, chloroform being more effective in this respect than ether No rabbit survived more than three fifteen-minute periods of chloroform anesthesia, whereas nine of the twelve rabbits survived the five periods of ether anesthesia, and are in good condition at present

* Read before the Section on Miscellaneous Topics at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

ABSTRACT OF DISCUSSION

Dr Morris H Clark, Kansas City, Mo The dictionary says that catalase is an enzyme which decomposes hydrogen peroxid returning to its original state at the end of the process That left me in the dark as much as ever Then I saw the *Journal of Biology* and the first sentence I came to was very helpful It said "Considering the tremendous amount of work that was done on this subject, it is very discouraging that we have learned nothing" I found one statement that caught my attention because I found it in several places that "catalase in the presence of hydrogen peroxid will liberate oxygen molecules" It does not make a bit of difference whether the oxygen or the amount of catalase in the blood is due to the number of red blood cells or catalase in the blood What we want to know is how much oxygen is liberated by the peroxid when blood is added If we find that less oxygen will be liberated in certain conditions, such as infections we can measure the severity of the infection by the amount of oxygen liberated If we find that anesthesia reduces the amount of catalase in the blood we know that we are getting some detrimental effect from the anesthetic These experiments are helping us to obtain something, and sometime we shall put them all together and evolve a definite theory that will be of absolute value

Dr F H McMechan, Avon Lake, Ohio In Burge's work we have evidence that caffein and theobromin, for all practical purposes, preserve the catalase functions of the liver during anesthesia In view of the fact that caffein and theobromin are such important drugs also, conserving kidney functions as well as catalase secretion would it not be very useful to have a series of experiments made, to determine the amount of caffein and theobromin which could be given to the normal or the serious risk patient coming to operation in order before operation was attempted at all to supply that patient with a reversible amount of these drugs to counteract any effect of the anesthetic which would have to be given during the course of the operative procedure? What I mean to say is this Is it a practical possibility to give the patient previous to operation and anesthesia such an amount of caffein as will not invalidate the anesthesia, but which irrespective of the anesthetic used or the duration of the anesthetic period will leave the patient in the same physiologic condition as though the anesthetic had not been administered because the caffein had taken care of the oxidative processes of the body in a physiologic way, during the surgical procedure?

Primitive Medicine and Religious Beliefs—If we are to understand the attitude of the primitive mind toward the diagnosis and treatment of disease we must recognize that medicine in our sense was only one phase of a set of magic or mystic processes designed to promote human well-being, such as averting the wrath of angered gods or evil spirits, fire-making making rain purifying streams or habitations, fertilizing soil improving sexual potency or fecundity, preventing or removing blight of crops and epidemic diseases and that these powers, originally united in one person, were he god hero king, sorcerer priest, prophet, or physician formed the savage's generic concept of 'making medicine'" —F H Garrison, History of Medicine '

UTERINE HEMORRHAGE OF BENIGN ORIGIN TREATED BY IRRADIATION

AN ANALYSIS OF FIVE HUNDRED AND TWENTY-SEVEN CASES OF MYOMA UTERI AND MYOPATHIC LESIONS *

JOHN G. CLARK, M.D.
AND
FLOYD E. KEENE, M.D.
PHILADELPHIA

We now have available for statistical study 527 cases of myomas and other benign lesions causing uterine hemorrhages which have been treated by irradiation in the gynecologic department of the university hospital. In various publications, we have defined from time to time the indications for and contraindications to this treatment, and we have carefully followed a set of rules which clinical experience has taught us are essential safeguards. The patient who falls into the hands of a radiologist who is not a surgeon, or the surgeon who does not employ this valuable remedy as part of his armamentarium, is indeed riding on perilous waters, for neither irradiation nor surgery can be employed exclusively if the best interests of the patient are to be served. Radium in the treatment of uterine hemorrhage of benign origin is chiefly applicable to patients in the fourth and fifth decades of life, but with proper precautions and in carefully selected cases, it may be employed successfully in younger women.

To bring this issue out more clearly, we shall discuss this treatment from the standpoint of age, and we have classified these patients as follows: adolescent girls and young women up to the age of 20, young women from 20 to 35, middle aged women from 35 to 45, and those entering the climacteric years.

ADOLESCENT GIRLS AND YOUNG WOMEN

Occasionally, without definable cause, young girls either menstruate excessively, the flow at times amounting to a more or less persistent metrorrhagia, which in many instances may not interfere greatly with health, but, on the other hand, may finally reduce the patient to a severe degree of anemia. Quite naturally, this condition may be a simple functional derangement incident to the inauguration of the menses, or it may be due to some more or less obscure cause, which is difficult to ascribe to a demonstrable patholgic lesion. Such cases usually tend to self-correction under appropriate hygienic and medical treatment, therefore we studiously avoid any direct gynecologic intervention until the patient's health is manifestly deteriorating. Since the cooperation between the ovarian impulse and menstrual function is so interdependent, our inclination has been to ascribe these irregularities to some deviation of ovarian function, since a curettage so seldom proves more than temporarily effective. But one should be most wary in using radium in adolescent patients on the very threshhold of young womanhood, because in sufficient dosage it will just as surely stop menstruation for all time as will double ovariotomy.

In no field therefore, should this agent be used with such precautions and to this end we hold the initial irradiation at a very small dosage with the possibility of only partial relief or even failure, with a view to a second irradiation, rather than resort at once to a more prolonged exposure with its dangers. In these young persons, after an examination under anesthesia for the purpose of accurately defining the pelvic conditions, we may with safety apply 50 mg. for from three to four hours. This usually proves effective in regulating the periods, but we never reach any conclusion as to its failure to cure under six months, for we fear the effects of a too early repetition of the treatment. Should the second irradiation be necessary, the first having been partially or wholly ineffective, we then increase the time from four to six hours, depending to some extent on the size of the uterus and the severity of the bleeding. In our experience, the second application is always effective.

Fortunately, these cases are of infrequent occurrence, hence, the very small number in our list. Precisely the same contraindication must influence one here as in all other cases, namely, in the presence of any inflammatory involvement of the tubes, irradiation is very postively contraindicated. Occasionally, a small cyst, or tuberculosis of the endometrium may be the hemorrhagic genesis. It is especially important, therefore, to exclude every possible cause for the metrorrhagia that might contraindicate the use of radium. In our series of 527 cases, there have been only five treated between the ages of 11 and 20 years. All of these patients except one were cured by the first treatment. One girl of 11 had 50 mg. applied for three hours, two, aged 15 had eight and five hour applications, respectively, two, aged 17, five and eight hours, respectively. One of these who was subjected to an eight-hour application suffered with flushes for one year—too perilously close to a menopause for comfort.

YOUNG WOMEN

In the cases of women, aged from 20 to 35, myomatous changes in the uterus begin to show their incidence in an increasing ratio, very few appearing between 20 and 25, but from then on gradually becoming more frequent. In women of this age, two controlling motives in life should be kept in the foreview (1) her maternal possibilities, and (2) the sexual life. While radium is most effective in inhibiting the growth and ultimately diminishing the size of the tumor during these ages, it is also equally powerful in inducing a premature menopause. Therefore, the patient should be studied from the standpoint of a myomectomy if possible, as this operation is unquestionably to be preferred, and should this not be feasible, we are as a rule, favorably inclined to a subtotal hysterectomy, with the preservation of the ovaries. In the first instance, the sexual and maternal physiology are not interfered with but rather promoted, while in the second, menstruation may continue and the sexual life is in no way disturbed.

With this disposal of myomas occurring in young women, it will be noted that surgical intervention takes decided precedence over that of irradiation, leaving relatively few cases open to the latter treatment. As a result of our experience, we usually restrict the dosage of radium to 50 mg. for from six to twelve hours in these younger women. In such instances, the menstrual periods may recur more or less normally after a variable period of amenorrhea. Seventy-seven patients falling within these ages were subjected to irradiation. The age distribution was as follows: from 20 to 25, eleven, from 25 to 30, eighteen, from 30 to 35, forty-eight.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

MIDDLE AGED WOMEN

In the group of women aged from 35 to 45 the question of the maternal possibilities as well as the sexual life of the person becomes of much less importance in the choice of treatment. Usually the maternal equation is either settled by the patient having a family, or the myomatous changes in the uterus have so distorted its structure as to render the patient sterile, or have made childbearing impossible. Further, the cessation of the ovarian function in women who have established sexual habits is of far less moment in its influence on this function, for the libido sexualis is now largely dependent on the psychic side of the individual rather than on the centers in the lower spinal cord, which are of capital influence in the inauguration of the sexual instincts.

If either of these phases stand out prominently in the patient's mind and she fears the abrogation of either, we incline toward surgical intervention. The ultimate happiness of the patient must have equal consideration with the restoration of physical health, for the latter without the former may have little merit in the mind of a patient suffering under a cloud of such misgiving. In such cases, a follow-up letter does not bring a very cheerful or grateful response, even though the patient's life may actually have been saved.

However, in considering the use of radium we find that this question has largely been settled by the fact that the patient has passed the fortieth year. At this period, therefore, the preference, in case of doubt, always falls in favor of radium, whereas, in the younger women, surgery is almost invariably the remedy chosen.

WOMEN IN THE CLIMACTERIC YEARS

In the group of cases formed by women in the climacteric years, radium occupies a premier position, it is effective, it is quick in giving relief, the treatment does not incapacitate the patient, it is safe, and it is followed by practically no immediate disabling sequelae or remote ill effects, as our summary will show. With our experience as a guide, we have ceased to summarize what may happen from three to five years after irradiation, for, without exception thus far, we have nothing to record in the way of so-called continuing or remote changes which may be counted as a backfire from the treatment.

This statement is now well grounded on the careful study of cases running back six years. The fear of sarcomatous transformation of the tumor is without foundation, for in not one single instance has this malignant change been noted after irradiation in this large series. Hence, any criticism of radium treatment on this false assumption is without support. The cure in these cases is prompt, and the only after-effects are those noted in all women passing through the menopause. Many pass through this trying period with scarcely a complaint, others are troubled constantly, while a few have a very stormy and occasionally, a prolonged period of adjustment. At times, we have thought that possibly a menopause induced by irradiation is more violent than in other series of cases in which the climacterium is surgically induced, but when a large series of patients who have undergone double ovariotomy is compared with those who have been submitted to irradiation, the two are found to be similar.

In a review by Norris and Clark of two comparative series of myomatous and of pelvic inflammatory cases, in which the ovaries were preserved or removed, Norris, after a very close scrutiny of the results according to the age incidence, brought out a rather startling and revolutionary point which is fully substantiated in this study. In a large group of young women who have undergone double ovariotomy, there will unquestionably be a greater percentage who suffer acutely from climacteric disturbances, but it is strikingly evident that, in an equal number of patients either within or actually beyond the normal menopausal years, there will also be a considerable percentage in which these disturbances are quite as stormy and equally prolonged.

The temperamental and the nervous stability of these women has an infinitely greater bearing on this critical epoch than the mere question of age. For this reason, we study much more attentively than formerly the nervous status of the patient, when this decision as to the artificial induction of the menopause is under consideration. This is particularly to be taken into full account in young women, whereas, those who are within the menopausal years may be treated as the pathologic status indicates. This observation of Norris we especially emphasize, for it is of capital importance and must be carefully heeded if the best postoperative results are to be achieved.

SUMMARY OF RESULTS IN FIVE HUNDRED AND TWENTY-SEVEN CASES

The total number of cases of benign hemorrhage of the uterus occurring in myoma uteri and myopathic lesions is 527. Of this number, there are available for statistical study 476 cases which have been fully treated. Of the remaining fifty-one, some have not been heard from and others have been too recently treated for conclusive study.

After irradiation it is common for one or two and rarely three menstrual periods to occur before the actual onset of the permanent amenorrhea. To some extent the time of the application of radium relative to the menstrual epoch influences the succeeding periods. If radium is applied shortly before the expected period, it is not likely in any way to influence the succeeding period, to the contrary, it may actually be more profuse, but, we may assume that within from four to six weeks at most the structural changes induced by the irradiation will have progressed sufficiently to stop the menstrual flow entirely.

In 476 cases which required only one treatment, permanent amenorrhea occurred promptly, or, after a short interval of temporary amenorrhea, there was a return to normal flow, when the dosage had been intentionally light with this end in view. Of 433 cases, forty either required a second application of radium, or an operation was necessitated on account of a persistent flow. The actual percentage in which the bleeding was controlled by the first application of radium in 476 cases was 91 per cent. In this entire number, only one death occurred, and this was of obscure origin. The patient was very stout, and within twenty-four hours after a plastic operation on the vagina, accompanied with a simple dilation and curettage, and an intra-uterine application of 50 mg. of radium, she developed severe pains in the epigastric region, which soon defined itself as a general peritonitis, from which she died.

A necropsy was not permitted in this case, and we are at a loss to know how to account for the fatality, particularly as the initial symptoms began in the upper abdomen and not in the region of operation. We are

inclined to think that there was a second lesion in the upper abdomen, and the ultimate catastrophe may have resulted from the perforation of an ulcer or possibly from some accident incident to a gallbladder or pancreatic lesion

RECURRENCE OF BLEEDING AFTER IRRADIATION

In forty-seven cases, bleeding recurred after the application of radium, in twenty-seven, several months after the treatment. The remainder were noted as follows: one year subsequently, nine cases; from one to one and one-half years, two cases; from one and one-half to two years, three cases; from two to three years, six cases. Of these forty-seven, the recurrence was slight, or the periods returned to normal and did not require subsequent treatment, in twenty-three cases.

LEUKORRHEA

Frequently, after an intra-uterine application of radium, a thick yellowish leukorrhea develops, which is slight in amount and is seldom if ever persistent, rarely lasting more than from six to ten weeks. Frequently, it is so insignificant that unless the patient's attention is called to it, she does not refer to it. Further along this line, there is a gratifying sequel in that a persistent leukorrhea is not infrequently cured by the treatment. We, therefore, lay little or no stress on the presence of leukorrhea as a sequel, because it is evanescent in character, and requires little or no attention.

MENOPAUSE

Irradiation in a dosage of 50 mg., for twelve to twenty-four hours, will produce climacteric symptoms of varying degrees of intensity in 60 per cent of cases. In 36 per cent., the symptoms will be marked or severe. As a rule, they persist for from a few months to two or three years, and then subside. In an occasional case, severe symptoms may persist for several years. Menopausal symptoms seldom if ever occur in young women when a dosage of 50 mg. is applied for from six to eight hours, and in no case has the climacterium been induced by this dosage. Larger doses will produce these symptoms, but our impression is that they are usually neither so persistent nor so severe in younger women as those of menopausal years. Strangely, this observation is at variance with the usual conception of the menopause, but it is in line with the statement of Clark and Norris in their analysis of cases after a complete hysterectomy.

From this study, we also draw the conclusion that the age factor in its relationship to the menopause is not nearly so much to be taken into account as the temperamental and nervous factors. Thus, a highly strung woman with poor nervous governors is very likely to be thrown markedly out of balance by the precipitation of the menopause, be it early or late. This point we would especially emphasize.

PREGNANCY

As the vast majority of these patients were subjected to irradiation after childbearing possibilities had ceased either through age limitation or because of the distortion of the uterus incident to pathologic changes, the consideration of pregnancy has but little bearing as a deciding factor in the choice of treatment. As we have already indicated in the preceding pages, our inclination is to perform an operation in the younger women rather than to use radium.

In our total number of cases in which radium has been used, there have been five women who subsequently became pregnant. In one, a woman, aged 29, suffering with persistent menorrhagia of a myopathic character, in whom a three hour application of 85 mg. of radium was employed, the menses returned to normal after three preceding curettages had failed to effect this regulation. Two years after marriage, a full term healthy child was born. The second patient, aged 31, had suffered from excessive menorrhagia for ten years, induced by a myomatous tumor the size of a small orange. Subsequent to the irradiation with 50 mg. for twenty-four hours, she passed through a definite menopausal cycle. The periods then came back to normal for a short time and pregnancy occurred. She passed through a normal pregnancy up to full term, but succumbed to a postpartum hemorrhage, following the birth of the baby by accouchement force. In a third patient, pregnancy occurred two years after an application of 50 mg. for twenty-four hours, but resulted in a miscarriage. In a fourth, a normal delivery occurred after three years in a patient who had been submitted to an application of 50 mg. of radium for six hours. In a fifth patient, who had twice received applications of 25 mg. of radium for twenty-four hours, three pregnancies occurred. All of these children were born prematurely and were either dead at delivery or died subsequently.

From this summary of results it is very plainly evident that the application of radium gives but little forecast in favor of restoring the childbearing possibilities, for, of these seven pregnancies only two children came to full maturity. This study, therefore, emphasizes the statement already laid down that when pregnancy is still in contemplation by the patient, an operation should be advised, instead of irradiation.

LATE RESULTS OF IRRADIATION

The criticism offered to the use of radium has been that the final results of irradiation are not yet known. We believe that this skeptical forecast may be set at rest when we find in our large list of cases that, in at least 300 of them that have been followed from three to six years, thus far no single instance has come to our attention in which there was any remote deleterious result which could in any way be traced to radium.

In one instance, a patient who was operated on in another clinic after irradiation by us was found to have a carcinoma of the fundus. Previous to the treatment by us, a curettage had been done by a competent gynecologist and a negative report as to malignancy had been returned from his laboratory. The bleeding recurred after the curettage, and the patient then came under our care. The second curettage brought away insufficient debris for a pathologic examination. The hemorrhages had been absolutely periodic in character, the uterus was slightly enlarged, and there were no grounds on which to base a diagnosis of malignancy, all the evidence being in favor of a benign source of hemorrhage. Irradiation in this case caused a cessation of hemorrhage for several months, when it again recurred, and, at an operation in another hospital, an extensive carcinoma of the fundus was found. Whether there was an oversight at the time of the irradiation, or whether the carcinoma originated subsequently, is open to question. Admitting the probabilities that the carcinoma was overlooked at the time of irradiation, this was but one single instance in 527 cases of such an oversight, and, as we review our 96 per cent of permanent cures, we do not feel that this is a very serious indictment against irradiation, partic-

ularly as this error did not preclude the subsequent hysterectomy

FAILURE TO CONTROL BY ONE IRRADIATION

A reapplication was necessary for the relief of a continuation or a recurrence of the abnormal bleeding in twenty-eight cases In all of these, the condition was cured by a second application, except in two, which required operation The types of cases requiring a second treatment were myomas, eight cases, myopathic hemorrhage, five cases, endometritis two cases, bleeding from cervical stump, one case, pelvic inflammatory disease, one case, not stated, one case

Of this list, an error was committed in reapplying radium in the pelvic inflammatory case, notwithstanding the fact that the bleeding was controlled and the patient was relieved of the symptoms, for inflammatory cases should not be submitted to irradiation Further, it may be said of the twenty-eight patients that thirteen were subjected to 50 mg of radium from six to twelve hours In other words, in this list there were several young women in whom the light application of radium was made with the probability of having to resort to a second treatment

CASES REQUIRING OPERATION AFTER IRRADIATION

Of the 527 patients, a total of eighteen were operated on subsequent to irradiation Fourteen of these were myomatous cases in which the bleeding persisted or recurred more or less profusely following a variable period of amenorrhea Four patients were subsequently operated on for chronic pelvic inflammatory disease and one for hemorrhage It is gratifying to note that in this long list of cases only 3 per cent of the patients required operation after irradiation certainly a very small percentage in a series of cases of so many varied conditions

In the fourteen patients requiring a subsequent operation, ten of the operations were for myomas of the larger submucous type, three for myopathic hemorrhage, and one, in which there was recurrent bleeding from a cervical stump after a hysterectomy, for an adenomyoma

MORTALITY

In the entire series there was but one death which occurred from peritonitis a few days after an extensive plastic operation and an application of 50 mg of radium for twenty-four hours The postoperative symptoms were those of an acute upper abdominal lesion Necropsy was not performed

COMPLICATIONS OF IRRADIATION

Phlebitis occurred in two cases, in one a mere recurrent symptom of an old phlebitis In the second, bilateral phlebitis followed on a repair of the cervix, a posterior colporrhaphy and irradiation Eight patients developed symptoms of more or less severe neuritis, which is not an infrequent occurrence in women at the menopause, regardless of any antedating treatment or operation

TECHNIC

The technic of application is very simple Under nitrous oxid and oxygen anesthesia, a careful pelvic examination is made The size of the uterus is ascertained, and its depth is measured by a sound and recorded for future reference A thorough curettage is performed, and the curettings are saved for microscopic diagnosis A 50 mg tube of radium properly filtered is inserted to the fundus of the uterus The duration of application depends largely on the age of the patient, in women at or near the menopause, the duration is usually twenty-four hours, and in young women proportionally less A repetition of the application in young women is preferable to overirradiation

A point which we always emphasize in the use of radium in all cases of benign hemorrhage is that one intra-uterine application of 50 mg for twenty-four hours suffices to cure the case effectively We, therefore, strongly deprecate the repetition of these treatments, since each application carries a minimum danger with it, and has no merit whatever over one application which effectively cures Also, we do not favor coincident roentgen-ray treatments, for they are quite unnecessary

The immediate results of irradiation are not unlike those of a simple curettage, with the exception that nausea is likely to be more persistent during the retention of the radium within the uterus In all of this list, we have had no case of vomiting so persistent or prolonged as to give the slightest cause for anxiety Usually within one or two hours at most after the withdrawal of the radium, the nausea and vomiting cease In a few instances, these symptoms have persisted for three days As a rule, these patients remain in the hospital five days, for we follow the rule here that we observe in any case of simple curettage It is unwise to permit the patient to go home the second day after irradiation, since the surgeon must see the patient through any possible danger arising from his surgical intervention, and such dangers are not past within twenty-four hours As a rule, the patient sits up the third day and leaves the hospital the fifth day

The standing rule is for all of these patients to return for examination at the end of from six weeks to two months after the treatment If the patient lives at a distance and cannot return, a personal letter as to her condition is requested of the patient or of the attending physician From our study of these final results, we feel that a three-year period suffices for a complete observation By no means do all tumors disappear, and a few do not diminish greatly in size, but as the majority of these cases have been treated solely for hemorrhages, with the cessation of this symptom the patient may be looked on as cured After irradiation, the great majority of tumors either shrink greatly in size or disappear completely A subperitoneal tumor is not likely to be greatly influenced by irradiation

CASES IN WHICH OPERATION WAS PERFORMED AFTER INEFFECTUAL IRRADIATION

CASE 1.—*Myoma* One hundred milligrams of radium was applied for twenty four hours Operation was performed two months later There was no relief of hemorrhage A large tumor was found

CASE 2.—*Myoma large* Fifty milligrams of radium was applied for twenty four hours There was no effect on bleeding

CASE 3.—*Adenomyoma of cervical stump* Fifty milligrams of radium was applied for twelve hours There was no relief of hemorrhage

CASE 4.—*Myoma* Fifty milligrams of radium was applied for twelve hours The periods recurred in normal amount a few months after irradiation

CASE 5.—*Myoma large* Fifty milligrams of radium was applied for twenty four hours Two applications were made with an interval of ten months Bleeding was not controlled

CASE 6.—*Myoma* Fifty milligrams of radium was applied for eight hours Bleeding continued

CASE 7—*Myoma* Fifty milligrams of radium was applied for twelve hours Operation was performed two months later, as bleeding was not controlled

CASE 8—*Myopathic lesions* Fifty milligrams of radium was applied for twenty-four hours Operation was performed eight months later for recurrence of bleeding

CASE 9—*Myopathic lesions* Twenty-five milligrams of radium was applied for six hours Operation was performed two years later for recurrence of bleeding

CASE 10—*Myoma* Fifty milligrams of radium was applied for twelve hours Operation was necessary for recurrence of bleeding

CASE 11—*Myopathic lesions* Fifty milligrams of radium was applied for four hours There was persistent bleeding

CASE 12—*Myoma, large* Fifty milligrams of radium was applied for twenty-four hours There were two treatments, with an interval of nine months After the second treatment there was amenorrhea for two years, then a recurrence of bleeding

CASE 13—*Myoma* Fifty milligrams of radium was applied for twenty-four hours The tumor was large There was recurrence of bleeding after nine months, requiring operation

CASE 14—Fifty milligrams of radium was applied for fourteen hours Radium had no effect on bleeding Operation was performed six months later

CASES IN WHICH OPERATION WAS PERFORMED FOR SUBSEQUENT PELVIC INFLAMMATORY DISEASE

CASE 15—Operation was performed six weeks after irradiation This was a case of chronic pelvic inflammatory lesion, lighted up by irradiation

CASE 16—The patient was well for three years following irradiation, and then developed symptoms of acute pelvic infection of streptococcus type

CASE 17—Operation was performed one and one-half years after radium treatment for extensive pelvic inflammation

CASE 18—Radium was applied in this case which had been diagnosed as pelvic inflammatory disease at the time of the first treatment This was a cardinal error, for this treatment is not suited to pelvic inflammatory lesions

Having been among the first to adopt this plan of treatment following the pioneer work of Drs Abbe and Kelly, we have endeavored to thread our way cautiously, expanding the field of application only as our experience pointed the way, and we now feel that we are on a solid therapeutic foundation Following are clinical rules which have been evolved from our observations of this large series of cases

CONTRAINDICATIONS

1 Tumors larger than the size of a four months pregnant uterus, or those complicated by inflammatory lesions or neoplasms of the adnexa, should not be submitted to irradiation Hysterectomy offers quicker relief for the first, and surgical intervention is imperatively indicated in the second class In exceptional cases, large tumors have been successfully irradiated in the face of some grave contraindications to the major operation, and in others this treatment has been employed to check hemorrhage in seriously anemic patients, thus permitting a sufficient recuperation to insure a safer operation

2 In tumors causing pressure symptoms, the shrinkage of the tumor is too slow after irradiation, therefore, hysterectomy is to be preferred

3 When, in tumors, there is cachexia out of proportion to the blood loss, this may be due to a necrosis of the tumor, which may be hastened by the irradiation We have observed such instances The recovery of the patient is very prompt and most satisfactory after hysterectomy, and it is, therefore, preferable

4 The larger submucous tumors, and those so distorting the cervical canal and fundal cavity as to render the introduction of the radium capsule difficult or impossible, are not suitable for irradiation A pyometrium may follow the application of radium in such cases This sequel has followed in two instances

5 Tumors rapidly increasing in size or those which have undergone calcareous changes are not adapted to irradiation

6 Myomas in young women fall, as a rule, within the surgical domain, as a myomectomy or partial hysterectomy with preservation of the ovarian function, is decidedly preferable

7 In patients suffering with an associated intra-abdominal lesion, such as a cholelithiasis, appendicitis or gastric lesions of surgical consequence, it is injudicious to employ radium In such instances, an exploratory incision should be made, thus giving a comprehensive diagnostic insight The abdominal lesion may require first attention, but this does not preclude an irradiation at the same sitting, if the myoma or myopathic cause of the hemorrhage falls within the class to which this treatment is applicable Under this comprehensive plan, the treatment is fully subservient to the surgeon's judgment

INDICATIONS FOR IRRADIATION

From a study of the foregoing contraindications to irradiation, it appears at first glance that the field for its application must be a narrow one, and yet such is not the case In 1921, 210 patients falling within these two domains were admitted to the gynecologic service of the university hospital Of these, 110 were submitted to irradiation and 100 to surgical intervention Both classes of cases, under this careful segregation, yielded first class results Those undergoing an operation ran greater risks and were longer in the hospital, and the return to efficiency was much slower But the ultimate outcome was entirely satisfactory, since these patients belonged without question to the surgical field

We would commit a serious error were we to consider this splendid and most effective plan of treatment as a competitor of surgery The two go hand in hand, and both must be supervised by the surgeon and not by the roentgen-ray expert or the roentgenologist, for each in a varying degree is a surgical measure As to the indications for this treatment, we may briefly summarize it in one sentence "Irradiation is the treatment of choice for the smaller myomas in women approaching or within the menopausal years whose only symptom is hemorrhage"

2017 Walnut Street—Medical Arts Building

ABSTRACT OF DISCUSSION

DR HENRY SCHMITZ, Chicago In my work I observe the same indications as given by Dr Clark In every case of bleeding uterus to be treated with radium I insist on a diagnostic curettage The ratio between the cases treated with radium and those subjected to surgery is as 1 3 In other words, 25 per cent of so called benign uterine hemorrhages are treated with radium, and the other 75 per cent by surgery Therefore, the treatment of benign uterine hemorrhages belongs to the surgeon and should, under no circumstances, be undertaken by a radiologist unless the latter cooperates with the surgeon We have treated 142 cases up to date One patient died from septic peritonitis The patient was *the*

list of five patients being treated on this particular morning with radium for benign and malignant hemorrhages The same surgeon did the work in the same operating room The diagnostic curettage was negative The bimanual findings were normal We observed a case of carcinoma of the uterus in spite of careful diagnostic curettage and histologic diagnosis It was a cervical carcinoma Hemorrhage recurred six months after the treatment At this time the cancer had invaded the parametria Whether the carcinoma was present at the time of the insertion of the radium it is impossible to state as the microscopic report was negative It is fair to assume, however that the patient was suffering with cancer Another patient returned two years later with an advanced fundus carcinoma though the diagnostic curettage was microscopically reported as a hypertrophy Two sarcomatous degenerations were detected very soon after the treatment and were removed, so the patient did not suffer from procrastination We also saw four cases of degeneration fibroids three simple fatty degenerations and one red degeneration I have mentioned these observations not to discourage the use of radium in cases of benign hemorrhage but to bring out the point that it is extremely important to make a very careful diagnostic curettage and if we are in doubt to resort to surgery rather than procrastinate by the use of radium

DR F C LAWRENCE Columbus, Ohio The question seems to be first Shall we treat the symptoms? Shall we be satisfied with a symptomatic cure or relief? In some of the cases of radium and roentgen-ray treatment the results are apparently magical while in others the malignancy seems to be increased in its activity The first thing we should remember is that every neoplasm no matter where is potentially a malignancy Second that fibroma or myoma of the uterus while it develops malignancy is not carcinoma It may be the cause of carcinoma by its continued irritation, and produce in epitheliomatous growth which is carcinomatous With this potential malignancy we should ask ourselves Can we afford—when the operation of supravaginal hysterectomy for removal of the myomatous uterus has a mortality when properly performed of 1 per cent—to deal with this potential malignancy by any type of treatment other than complete removal? Noble and other competent men have shown, and probably Dr Clark has found that there is a potential malignancy in fibroma of from 5 to 8 per cent That is to say from 5 to 8 per cent of the fibromas when removed, have undergone sarcomatous change When we put against this 1 per cent mortality in hysterectomy properly performed can we afford to run from five to eight times the risk of malignancy by attempting to treat with radium or roentgen ray or anything else?

DR JOHN G CLARK Philadelphia Dr Schmidt raises the question as to mortality There was one fatal case among the 527 treated The death occurred from some obscure cause The symptoms were of a fulminating character and occurred in the upper abdomen from apparently some coincident lesion Neither an operation nor a necropsy was permitted, and we have designated this as a fatality from peritonitis induced by the curettage, although the symptoms would really not sustain this interpretation I am indeed, glad that Dr Lawrence has brought into the discussion the perennial question of malignant degeneration in myomas If there was ever a fallacy that should be annihilated this is one The frequency of sarcomatous transformations in myomas is so small as almost to be negligible If as Dr Lawrence would have us believe this peril is so ominous certainly sarcomatous sequels in the cervical stump after a supravaginal hysterectomy should frequently be noted and yet in more than 1 500 such operations we have yet to see such a postoperative incident In our laboratory, in which more than 1 200 uteri have been examined after hysterectomy for myomas, there were only twenty-two sarcomas that were not diagnosed before the specimen was sent to the laboratory The hiatus in pathologic statistics emanating from different laboratories depends on what one pathologist would call sarcoma and what the other would call fibroma It is quite possible to take out of almost any fibroid tumor isolated areas which could very easily be mistaken for spindle cell sarcoma In such instances the whole specimen is of chief diagnostic import not these compact areas I am sure, therefore, that the discrepancy in diagnosis lies in this difference in interpretation We have seen several carcinomas occurring in the cervical stump in which a previous supravaginal hysterectomy has been performed but a control diagnostic curettage had not been made As these cases have passed through our clinic there were 101 cases of adenocarcinoma of the uterus in which the clinical diagnosis was positive in fifty-seven and doubtful malignancy, twenty-four, in the remainder the positive diagnosis was made in the laboratory in cases which otherwise would have been considered of benign type In such instances proper surgical measures were instituted before the patients were discharged from the hospital The ultimate judge, therefore in all of these cases whether one uses radium or operates, is a skilled pathologist All too frequently a good general pathologist goes completely amiss on this point, for he may see in normal cyclic glandular changes in the endometrium such puzzling pictures that he may designate them as adenocarcinoma The main point which I particularly wish to stress is that we should cease to hold over patients the suggestion that a myoma is liable to sarcomatous changes, for such transformations are so small as almost to be negligible and should never be the crucial point on which a radical operation is decided Dr Lawrence admits at least a 2 per cent mortality from surgical intervention Therefore, in this series were they all to have been submitted to hysterectomy, there would have been at least ten deaths under irradiation there has been one

STANDARDIZATION AND PRESERVATION OF COMPLEMENT SERUM FOR WASSERMANN TEST*

E H RUEDIGER M D
BISMARCK, N D

Laboratory workers who are familiar with the Wassermann test know that the serums from different guinea-pigs differ greatly in complement activity, and that under ordinary conditions complement rapidly deteriorates but can be preserved for varying lengths of time under suitable conditions

About two years ago I[1] showed that a number of complement serums from guinea-pigs gave results with the same human serum varying from 2+ to 10+ Even greater differences have been observed since, serums from some guinea-pigs have given negative results while serums from other guinea-pigs gave 10+ with the same human serum Such irregularities can be eliminated by selection of complement serum, probably by selective breeding of guinea-pigs, by selective feeding of guinea-pigs and by preservation of the good complement serums

SELECTION OF SERUM AND GUINEA-PIGS

The preserved positive control serum, composed of a mixture of twenty syphilitic human serums, I diluted to such an extent that it gave approximately 6+ with a fairly good complement serum This diluted positive control serum was then used in titrating the complement serums from the different guinea-pigs At the beginning of this work, about two years ago, the differences in the results were very striking, they varied from negative to 10+, and from no hemolysis to complete hemolysis All guinea-pigs whose serums gave less than 5+ or had poor hemolytic power were rejected and were used for other work or were killed

* From the pathologic laboratory of the Bismarck Evangelical Hospital

1 Ruediger F H Journal Lancet 40 565 (Oct 15) 1920

At the first time I titrated the serums of all guinea-pigs I had I rejected approximately 50 per cent as absolutely unfit for the Wassermann test A selected few those whose serums had good hemolytic power and gave 10 + or more with the positive control, were kept as breeders and the others were kept for the Wassermann test For the Wassermann test each guinea-pig serum is titrated and at least six selected serums are mixed Selective breeding has been carried on for nearly three years, when I started I rejected 50 per cent as worthless, and of approximately 100 guinea-pigs raised last summer under selective breeding I rejected only 5 per cent as worthless, 50 per cent fell into the exceptionally good class

INFLUENCE OF FEED ON COMPLEMENT

In winter, a number of selected guinea-pigs were divided into four groups, called A, B, C and D Group A was fed on raw carrots, raw cabbage, raw lettuce, raw apple peelings, hay, oats and bread Group B received raw carrots, hay, oats and bread, Group C received raw cabbage, hay, oats and bread, while Group D was fed on raw potatoes, hay, oats and bread All received as much water as they wanted After one month of special feeding, the serums of all the guinea-pigs were again titrated, and they were all good A barely perceptible superiority was found in Group A over Groups B, C and D

Last fall the complement serums of a number of grass-fed guinea-pigs gave 8 + with the preserved positive control serum During the winter the fixability gradually rose, reaching about 20 + by spring, and in two weeks on the fresh grass diet the fixability abruptly fell more than 50 per cent The serums of guinea-pigs which gave 8 + last fall and 20 + toward spring now gave only 6 +, while the hemolytic power remained unchanged or nearly unchanged

PRESERVATION OF COMPLEMENT SERUM

Among the methods commonly employed to preserve complement serum, freezing the serum or salting the serum appear to be the most successful In 1919 I reported on a more or less unsuccessful result I had with with frozen complement serum At that time I tried it under unfavorable conditions During the winter months the complement serum was kept outdoors but, as the temperature varied greatly, I had to pack small test tubes with complement serum in salt and ice The serum was usually worthless in three weeks The only explanation I can offer for that rapid deterioration is that salt or brine got into the tubes Salt (crude sodium chlorid) is strongly anticomplementary, hence a small excess renders a complement serum unfit Since that report I kept complement serum at a temperature of below zero Fahrenheit in a cold storage room for which I am indebted to the Northern Produce Company at Bismarck, N D Kept in the cold storage room at a temperature below zero Fahrenheit, complement remained active for from eight to ten weeks Practically no deterioration could be detected in a month

Adding salt to complement also helps to preserve it At ordinary refrigerator temperature I find that it deteriorates in less than two weeks Salted complement kept at approximately 1 C remained active for from four to six weeks, one lot was still good after eight weeks

2 Ruediger E H J Infect Dis 25 269 (Sept) 1919

SUMMARY AND CONCLUSIONS

The serums from different guinea-pigs differ greatly in fixability and in hemolytic power

In order to obtain fairly uniform complement serum, the serums must be selected, the good serums being used and the poor serums rejected

Breeding only guinea-pigs with good complement greatly improved our collection of guinea-pigs for this purpose in three years

Any raw vegetables, such as potatoes, cabbage or carrots, prevent scurvy and are suitable winter feed for complement guinea-pigs A mixture of raw vegetables gives the best results

The fixability of guinea-pig complement was much better in winter than in summer, which may be due to the large quantity of grass fed in summer

Frozen complement serum kept below zero Fahrenheit in the cold storage room remained active for eight weeks

Salted complement serum kept at approximately 1 C remained active for more than four weeks

---

PREMATURE INFANTS

MALFORMATIONS AND DISEASES OF THE NERVOUS, OSSEOUS AND MUSCULAR SYSTEMS REQUIRING CORRECTIVE TREATMENT *

JULIUS H HESS M D
CHICAGO

According to the general use of the term we designate as premature all infants who are born before the end of the normal term of pregnancy (forty weeks), but in common usage the term refers only to those infants whose gestation period was 260 days or less There is another class of infants who may be considered in practically the same category as premature infants—the weaklings, infants born at term or nearly at term who have suffered more or less severely during their intra-uterine existence through factors which interfered with their nutrition, and consequently interfered with their development They are classed as congenitally diseased infants

For our purposes, we shall consider the conditions most frequently seen in premature infants which are of especial interest to the surgeon in three groups (1) congenital malformations of the fetus due to intrauterine diseases and deformities, (2) pathologic conditions developing at or shortly after birth, and (3) those developments of nutritional disturbances during the first months of life which result in secondary complications of the osseous, muscular and nervous systems

CONGENITAL MALFORMATIONS DUE TO INTRAUTERINE DISEASES

In the first group, constitutional defects and congenital malformations can be given only the most superficial consideration, because of the large variety and need for individualization in treatment Organic diseases of the central nervous system, with resulting disturbances in growth and deformities, frequently cause premature expulsion of the fetus

Cephalocele.—Early death ensues in anencephaly, while encephalocele and meningocele are often amen-

* Read before the Section on Orthopedic Surgery at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

able to surgical procedure When the deformed structure contains a cavity corresponding to a ventricle, the terms hydro-encephalocele and encephalocystocele are applied The latter deformities incline to a rapid increase in size while those which are not connected with the cerebrospinal canal tend to remain stationary Three principal types of encephalocele are to be distinguished frontal, occipital and basal The frontal types most frequently appear between the frontal bone and the nasal process Rarer forms are noted, such as the naso-orbital and the naso-ethmoidal The occipital is the most common form of cerebral hernia, and is usually seen at the nape of the neck, above or below the external occipital protuberance The basal variety is noted in the nasal or pharyngeal cavity

Spina Bifida—When the embryonic medullary tube fails to close properly, deformities result, corresponding to the nature and location of the opening The open congenital fissure of the spinal column, termed rachischisis, is invariably fatal The closed types, spina bifida cystica are generally situated in the dorsolumbar or lumbosacral regions of the vertebral column and, more rarely in the cervical regions Any of these forms of spina bifida may occur as a myelocele, myelocystocele or meningocele

Treatment in all of these cases of encephalocele and spina bifida is essentially surgical when the infant's development permits of interference The decision as to early or late operation must, of necessity, be dependent on the fetal age of the infant and the gravity of the symptoms Deformities most amenable to operation are those with a small pedicle and limited communication Operation may frequently be delayed through repeated paracentesis, with intermittent indications for operation Hydrocephalus frequently accompanies spina bifida, and is one of the most common complications secondary to operation, even in what appear to be favorable cases

Numerous efforts have been made by different methods for the relief of internal hydrocephalus with, and without, spina bifida Among the methods, drainage in the subdural space, under the scalp, into the jugular veins, and puncture of the corpus callosum have been among the most popular, but these procedures have given little more than temporary relief in the cases which have come under my observation More recently, Dr Alfred Strauss has operated in a series of six cases removing a cylinder of cortex, about three-eighths inch in diameter, from the frontotemporal region The plug of cortex extending into the lateral ventricle was removed with a piece of glass tubing with sharpened edge, after the skull was opened at a lateral angle of the large fontanel and the dura was incised and sutured to the arachnoid In the experimental animals, the defect in the cerebral cortex remained permanent in five out of seven cases, and in some of them, the lumen was found at necropsy to be lined by endothelium, probably from the lateral ventricles Six infants on whom operation was performed are all living, with no visible evidence at this time of disturbances of sensation or muscular power In the cases associated with spina bifida with the exception of one case, the operation for removal of the cerebral cortex was performed eight or ten days previous to the spina bifida operation In one case, the two operations were done at the same sitting The results have been such in these cases as to encourage further development of the procedure described It is to be remembered that little can be expected from major operative procedures before the infant has attained a fetal age and development approximating full term

Other Congenital Abnormalities—Numerous other congenital abnormalities of the skeleton are seen in infants prematurely born, some of which are due to developmental defects or displacements, and a considerable group of which are secondary to the posture of the fetus within the uterus Among congenital abnormalities of the trunk skeleton, the most common are scoliosis and kyphosis of the vertebral column, and deformities of the thorax The latter may result from improper development of the lungs, as in congenital atelectasis congenital heart conditions and diaphragmatic hernia More rarely, chest deformities may be secondary to lack of ossification of the ribs Malformations of the extremities are not uncommon, and vary from defects of all the extremities to rudimentary formation of the distal part of a single extremity Of the congenital changes of position and permanent contractures the most frequent are club-foot and club-hand The deformities are often multiple and may involve the larger joints as well, such as the hip joint, knee shoulder elbow and jaw Congenital dislocations of the hip are the most important of this type of deformities However, any of the joints may be involved Intra-uterine fractures may result from abnormal bone development, constriction by amniotic bands or intrauterine trauma Abnormalities of the skull may necessitate mechanical support in order to avoid further deformity The conditions of harelip and cleft palate in the very young present feeding problems rather than surgical ones Among the more common congenital diseases involving the bones and joints are mongolian idiocy chondrodystrophia and osteogenesis imperfecta Cretinism may result in premature birth, and is associated with delayed ossification The retarded skeletal and muscular development leads to malformations requiring correction

PATHOLOGIC CONDITIONS DEVELOPING AFTER BIRTH

In the second group of pathologic conditions affecting the growth and development of premature infants, I will include those becoming manifest shortly after birth The most important conditions encountered are those affecting the nervous system These are usually dependent on one of two causes, either birth hemorrhages or hydrocephalus Birth hemorrhages of the intracranial type belong in two groups In the first group may be included prenatal intracranial hemorrhages, which may have been the cause of the premature expulsion of the fetus, and in the second group hemorrhages within the cranial cavity and spinal canal which result from trauma secondary to labor, or a tendency to spontaneous hemorrhages Ylppo believes that intracranial hemorrhages are responsible for 30 per cent of the deaths of premature infants in the early days of life Hemorrhages from tears of the tentorium and subdural hemorrhages, which are the most frequent forms seen in full-term infants, are only exceptionally seen in premature infants In the latter, the hemorrhages within the cranial cavity are usually subarachnoidal or intrapial, but, in the spinal column, the hemorrhages are more commonly extradural Ventricular hemorrhages are frequently found in premature infants, but hemorrhage into the brain substance proper is quite rare Spontaneous hemorrhages, which occur in considerable number can usually be distinguished by a study of the coagulation time of the blood

Fortunately, many infants who suffer from intracranial hemorrhage escape mental disturbances, probably in large part because of a lack of development of the bony structures of the skull, allowing the brain to accommodate itself to the increased intracranial pressure Most of the infants, however, are less fortunate in escaping the different types of paralysis, which may involve the trunk muscles and from one to all of the extremities Therefore, infants and children who are mentally normal, or even precocious, with varied degrees of spastic paralyses, are not uncommon On the other hand mental defects in premature infants are in at least 75 per cent of all cases, accompanied by spastic monoplegias, paraplegias or diplegias Paraplegias or diplegias have been reported in more than 3 per cent of all the cases of surviving premature infants The figure would undoubtedly be much higher had all premature infants remained alive, since most of the infants suffering from injuries to the brain die very early The average coagulation time in full-term newborn infants is seven minutes as estimated by the Rodda method In icterus, melena jaundice due to syphilis, and nontraumatic cerebral hemorrhage, the coagulation time of the blood is prolonged in most instances, to such a degree that the diagnosis is readily made by a study of the coagulation time The subcutaneous injection of human serum is the most efficient method of treating delayed coagulation or slow bleeding The further early treatment must of necessity be symptomatic and expectant There is always a possibility that spontaneous cure may result Lumbar puncture, although primarily used as a diagnostic measure, may have a beneficial therapeutic value While decompression, with removal of surface clots, is to be recommended in hemorrhages in full-term infants, little can be expected in premature infants unless they have had almost the full period of gestation

For the various types of paralysis, mechanical corrective measures should be undertaken early, in order to prevent marked deformities Massage and active and passive movements should be practiced regularly before the end of the first year Muscle training in walking climbing and other activities should be instituted under the supervision of a trained assistant Orthopedic appliances are frequently indicated Surgical procedures may be necessary later

Hydrocephalus—True congenital hydrocephalus is usually of the internal type and associated with *enlarged ventricles The external form is rare* The megacephalic head (Yippo) of the premature infant is frequently described as a hydrocephalic head, to which it has no relation Megacephaly is dependent on the fact that the brain growth continues at its normal or a greater rate while the remainder of the body is retarded in its development, resulting in a disproportion between the size of the head and the body

Congenital hydrocephalus may follow blocking of the aqueduct of Sylvius, the foramen of Luschka or the foramen of Magendie, giving rise to the so-called obstructive type This may be due to a congenital abnormality, however, for more often obstruction is the result of intra-uterine serous meningitis or meningoencephalitis Congenital hydrocephalus of the second large group is due to interference with the absorption of cerebrospinal fluid from the subarachnoid spaces, following intra-uterine inflammation of the meninges, with resultant adhesions causing obliteration of the foramina and the cisterns Syphilis, in all probability, is more frequently the cause of congenital hydrocephalus in premature infants than in full-term infants In the latter, it is estimated that not more than 20 per cent of the hydrocephalus is due to syphilis Intracranial hemorrhages and cystic formations may be associated with secondary hydrocephalus

Many of the infants show an enlargement of the head at the time of birth, however, the hydrocephalus may become evident only after a latent period A marked retardation in the development of the brain may result The head need not be enlarged, in fact, it may be very small, as in microcephalic idiots, the brain being little more than a large cyst In many instances, shortly after birth, hypertonus and spasms of the muscles, increased reflexes and general convulsions are to be noted In others, apathy, shallow respiration and feeble heart action are present early, giving indications of involvement of the central nervous system When the characteristic enlargement of the head is absent, the diagnosis may be different Intracranial hemorrhages and meningitis must be ruled out Lumbar or ventricular puncture may be of assistance

The prognosis as to life and physical and mental development is dependent on the underlying pathologic condition The only early therapeutic measure is lumbar or ventricular puncture, with drawing off of cerebrospinal fluid Later, surgical interference may be indicated

Traumatic Injuries—Trauma, with fractures, epiphyseal separations and dislocations and nerve injuries resulting from labor are seen in a greater percentage of premature infants than in full-term infants Owing to the inability of these weaklings to give expression to their pain and discomfort, the pathologic conditions may go undiagnosed for weeks The infants should be viewed as potential subjects for traumatic injuries in all cases in which version and manual extraction are practiced Roentgenograms should be made in very doubtful cases Early institution of surgical measures is necessary to minimize deformities

NUTRITIONAL DISTURBANCES DURING FIRST MONTHS OF LIFE

In the third group of pathologic conditions affecting the growth and development of premature infants, nutritional disturbances during the early months of life, secondarily affecting the nervous, osseous and muscular systems, are especially common to premature infants In fact, the infants of this class escaping without such affections are the exception, and their absence suggests an understanding of their needs by the physician and attendants, and the institution of proper feeding and general care It has been my experience to come in contact with large numbers of cases in which nerve, muscle and bone pathologic conditions were unrecognized until gross deformities had developed Every premature infant should be viewed as a potential case of rickets, spasmophilia and secondary anemia, and the possibility of latent scurvy should be considered The fact must not be overlooked that premature infants develop manifest clinical evidences of rickets and secondary anemia by the second to the fourth month, while full-term infants rarely show bone lesions of rickets which can be diagnosed before the fifth or sixth month by roentgenograms

Rickets—The more prematurely born the infant is, the greater is the tendency to develop severe types of rickets, and, in infants born in the seventh and eighth

months of fetal life, even human milk is not an absolute protection against the development of pathologic conditions in the bone and muscle

The etiology is to a large extent dependent on three important factors first, the chemical constitution of the premature infant, which differs from that of the full-term infant, the salt content of the body being far below the normal second, underfeeding, third, improper environment Bunge, in his researches, found that the body of the average 4 months old fetus contained 14 gm of ash at six months, 30 gm, and, at nine months, 100 gm showing that two thirds of the minerals of the full-term infant were due to retention occurring during the last three months of fetal life In the new-born fully 75 per cent of the ash is made up of calcium and phosphate, which represent the chief constituents of the bones From 85 to 90 per cent of the bone ash is composed of calcium phosphate, from 10 to 15 per cent of calcium carbonate, and a small amount of magnesium phosphate

In premature infants there is also a very low calcium retention during the first months of life (Hamilton) This is probably dependent on several factors, among the most important being the low mineral content of the body at birth and the restricted intake of foods which in themselves are low in calcium and phosphorus, such as breast milk and cow's milk mixtures of high dilution In the light of our present knowledge we cannot but be convinced that sunlight plays an important part in the mineral metabolism of the body It is the common experience to find the premature infant stored away in a secluded corner of a poorly ventilated and, not infrequently, dark room or, even worse, in a closed incubator

Pathology Rachitic premature infants show bone changes which present a pathologic picture different from the lesions seen in full-term infants, which develop at a later period during the first year They are chiefly characterized by the development of megacephaly, characterized by a large round head with prominent frontal and parietal eminences and wide open sutures Megacephaly (Ylppo) in the literature is commonly spoken of as hydrocephalus, with which, in the majority of cases, it has no relationship, the main exceptions being syphilis and conditions causing obstruction in the cerebrospinal canal, and spina bifida The apparently large head in these cases is due to the fact that the growth of the brain tends to continue at its normal or a greater rate while the development of the remainder of the body is to a large degree retarded The changes in the long bones often lead to error in diagnosis because of a typical change in the zones of proliferation Only rarely are broadening, cupping and saw-tooth changes noted at the epiphyseal borders More commonly the metaphysis is seen as a straight line with a hazy appearance of normal breadth, while the cartilage alone is enlarged Similar changes are observed at the costochondral junctions Clinically, therefore, a moderate enlargement is noted at these points while roentgenologically only minor changes are seen in the bones

Pathologic fractures are of frequent occurrence and are usually partial, with a resulting deformity due to angulation These are especially common in extreme cases of tetany, owing to overaction of the muscles in the presence of carpopedal spasms

Treatment Prime importance must be placed on a careful study of the previous diet and life history of the infant In consideration of the preceding diet, the cases may be classified into the breast-fed and the artificially fed In the breast-fed, the diet usually errs in the direction of an insufficiency Breast milk contains 2 gm of ash per thousand cubic centimeters, of which 0.458 gm is in the form of calcium Holt, in his studies on calcium metabolism, found that breast-fed infants required 0.06 gm of calcium per kilogram, or about 120 c.c. of breast milk per kilogram Because of the obstacles to be overcome in feeding these infants, most of them, therefore, receive an insufficient amount of food to meet the needs during the first weeks In the artificially fed, even though cow's milk averages 1.72 gm of calcium per thousand cubic centimeters, because of the difficulty of digesting this food and the use of high dilutions, even greater obstacles present themselves The same may be said of the feeding with proprietary foods all of which are poorly balanced in their salt content

Hygiene The infant should at all times receive a sufficient amount of warm fresh air, and should be exposed to the sun's rays during the day As soon as the infant has developed sufficiently to permit handling (mothering) in the form of frequent changes of position and light, massages are invaluable The infant must at all times be protected from infection Orange juice and cod liver oil, the latter combined with phosphorus should be added to the diet in small quantities at the end of the first month of life In the artificially fed fresh cereals in the form of well cooked gruel can usually be added by the fourth month of life, and fresh vegetables in the form of a vegetable-cereal soup may be started by the sixth month

Deformities.—Development of deformities of the osseous system, more especially of the spine and long bones, can be to a large extent prevented Infants should be discouraged from walking until the bones are firm Head deformities can be lessened by changing the position in which the infant sleeps Scoliosis may be avoided by preventing the child from bearing weight on the spine through early attempts at sitting, and by preventing improper holding and carrying of the infant Bowing and distortion of the legs often follow crossing of the legs around the pot-belly Coxa vara is due to bearing the weight of the trunk before sufficient calcification has occurred Many of the deformities may be avoided by the institution of proper orthopedic measures Massage is of great value in strengthening the weakened muscles

Secondary Anemia.—Closely associated with rickets is an anemia which develops quite regularly and strikingly during the first three months of life There is a very distinct and early hemoglobin impoverishment which reaches its maximum in the third or the fourth month Lichtenstein believes that the early anemia in the first three months of life is a hypoplastic condition resulting through insufficiency of the hematopoietic system The later oligochromemia is probably a sequel of impoverished iron storage Landry has shown that the older the fetus, the higher the iron content of the body Diseases in the mother, such as nephritis, anemia and tuberculosis, of necessity have a direct influence on the iron content in the infant The low iron content of breast milk, 0.0017 gm per liter, and of cow's milk 0.0007 gm per liter, with the minimum intake of food and difficulties of metabolism, all have a direct bearing on the development of anemia as have also lack of fresh air and sunshine The blood picture in the well,

breast-fed premature infants, and in those showing alimentary disturbances, shows an anemia of chlorotic type

Treatment For the general and hygienic treatment of primary and secondary anemia, the suggestions made for general measures in the care of rachitis should be followed The infant must, above all, be given the advantage of a good environment, plenty of fresh air and sunshine

Iron therapy for the purpose of increasing the iron content of the tissues and the hemoglobin should be started early Among the iron compounds to be recommended are ferri carbonas saccharatus, ferri et ammonii citras or ferri lactas in doses of from 0 03 to 0 12 gm (½ to 2 grains) from one to three times daily

Small doses of liquor potassii arsenitis, from 0 03 to 0 06 c c , may be given one or two times daily for short periods The infant should be observed carefully for evidence of arsenic intoxication In the presence of congenital syphilis, mercurial therapy is imperative and may be combined with the arsenic treatment to good advantage

It is of the greatest importance to bear in mind that, as in the case of rachitis, the treatment for anemia should be started early It is our custom to begin the prophylactic treatment of both of these conditions in the first weeks of life

Spasmophilia —The term spasmophilia diathesis, as applied in the clinical sense refers to a constitutional anomaly characterized by a general hyperexcitability and irritability of the nervous system The most frequent active manifestations are general convulsions laryngospasms, spasmodic apnea and carpopedal spasms Among the latent manifestations are Chvostek's facial phenomenon and Trousseau's sign Among the most constant findings is Erb's sign, the presence of hyperexcitability of the peripheral nerves, as evidenced by increased reaction to the galvanic current

Spasmophilia appears earlier in premature infants than in full-term infants, and may be manifest as early as the sixth to the tenth week of life The blood of these infants shows a marked decrease in its calcium content Kramer, Tisdale and Howland found the calcium of the blood serum, in the presence of active manifestations, in the average of their cases to be 5 6 mg per hundred cubic centimeters of serum, as compared with from 10 to 11 mg in normal infants, while the inorganic phosphorus of the serum, in about half their cases, was within normal limits or slightly above normal This is in marked contrast with cases of rickets uncomplicated by tetany, in which they found a much reduced inorganic phosphate serum content The significance of this relatively high phosphate content in the presence of decreased calcium, in cases of rickets complicated by tetany, is as yet unexplained The interest of the orthopedists in tetany depends to a great extent on the secondary complications, such as intracranial and intraspinal hemorrhages following convulsions, and the fractures and deformities secondary to tonic carpopedal spasms Several cases of fracture due to prolonged and powerful contraction of the extremities have come under my care Such deformities necessitate prompt general dietetic and medicinal treatment, reduction of the deformities and immobilization

Scurvy —All that has been said of the etiologic factors of rickets has an equally important bearing on the development of scurvy Many cases of latent scurvy undoubtedly remain unrecognized The severer types of hemorrhage and cases complicated by pathologic fractures, epiphyseal separation and intracapsular hemorrhage need surgical care as well as dietetic treatment

5717 Blackstone Avenue

ABSTRACT OF DISCUSSION

Dr W McKim Marriott, St Louis Dr Hess has brought out two important points, first, that a premature baby is potentially an orthopedic patient, and secondly, that realization of this fact early enough may prevent a great deal of trouble later on It is a fact not generally recognized that birth hemorrhage occurs more frequently in premature infants than in those born at term, even though the latter may be delivered by forceps A certain number of premature infants during the first few months of life slowly develop a condition of opisthotonos This does not seem to be dependent on birth hemorrhage It has been our experience that the most satisfactory way to treat these infants is to keep them on the Bradford frame continually until there is no more tendency to opisthotonos Unless this is done, the deformity may last a long time Such a large proportion of premature infants develop rickets that it seems safe to consider that they will all develop rickets ultimately, and to treat them accordingly It is advisable as a routine, to give every premature infant a small amount of cod liver oil, 5 drops, three times daily, is usually sufficient to prevent rickets in infants of this type There is no advantage in adding phosphorus to the cod liver oil A certain number of premature infants who develop rickets may also show evidences of spasmophilia or tetany, as Dr Hess has mentioned, and this may secondarily lead to cerebral hemorrhage as a result of the convulsions The specific for tetany is calcium To control the active manifestations, large doses of calcium chlorid are required from 10 to 15 grains, four or five times daily

Dr Julius H Hess Chicago After illustrating some of the pathologic conditions encountered in premature infants, I would say that they are in great part worth saving They are deserving of the full consideration of the diagnostic group of the hospital in which they are born and not the least important factor in proper orthopedic inspection

SUBSEQUENT COURSE OF A CASE OF ADDISON'S DISEASE

LEONARD G ROWNTREE, M D
Director of Medicine the Mayo Foundation
ROCHESTER, MINN

Under the heading "An Autograph History of a Case of Addison's Disease," the late Dr A L Muirhead [1] gave an unusually interesting description of the clinical course of his own illness In this report we find a professor of pharmacology investigating and recording the subjective and objective results of treatment on himself, and the effects of drugs on the course of Addison's disease, from which he suffered and eventually died I will record the course of events subsequent to his report, which covered his illness until December, 1920

CLINICAL COURSE

Dr Muirhead left the Mayo Clinic, Aug 11, 1920, and for several months continued to improve The pigmentation had almost disappeared and he was able to resume his work as professor of pharmacology in Creighton Medical School Improvement continued until Jan 25, 1921, when there developed a gastric upset, loss of appetite, abdominal discomfort and weakness accredited by Dr Sachs, his personal

1 Muirhead A L An Autograph History of a Case of Addison s Disease J A M A 76 652 (March 5) 1921

physician, to hyperacidity The attack yielded somewhat to sodium bicarbonate, magnesium oxid and bismuth so that he was again able to return to his work However, the weakness persisted and he was placed on digitalis Subsequen to January 25, the salivary secretion was deficient, and he lacked appetite and could not relish food He continued on suprarenal treatment, epinephrin solution 1 1,000, 3 minims, twice a day hypodermically, rectal injections of 1/100 gram of the whole gland, and two capsules, 10 grains each, of whole gland, by mouth, at night In February, the weakness and shortness of breath became more pronounced He suffered from pain in the left upper portion of the chest which Dr Sachs called "low pressure angina" The pain was relieved by heat, exertion food and nitroglycerin

In March, 1921, Dr Muirhead returned to the clinic, complaining of extreme weakness which confined him to bed and of pain in the left shoulder The pigmentation was marked He was extremely asthenic, and suffered almost constantly from gastro intestinal symptoms, especially burning in the stomach The heart was slightly enlarged and the sounds were of poor quality An electrocardiogram disclosed a rate of 92, sinus tachycardia, notched QRS complex in all leads arborization block, and slight right ventricular preponderance The blood pressure was 86 systolic and 54 diastolic, the blood urea was 56 mg for each hundred cubic centimeters, and the uric acid 2 8 mg The hemoglobin was 68 per cent, and the erythrocytes numbered 3 820 000 The patient ate very sparingly, and toward the end of his stay developed a mild acidosis He left the clinic, March 23 unimproved The subsequent course of the disease is submitted in Dr Sachs' report

"The blood pressure just prior to his death was 84 systolic and 60 diastolic Dr Muirhead had a mild acidosis from time to time, for which he was given alkalis Alkalis during the latter part of his illness distressed him greatly and were discontinued His gastric acidity changed from a hyperacidity to a hypo-acidity He progressively became more asthenic until it became difficult for him to swallow He gradually lapsed into coma, and died, April 26, 1921"

REVIEW OF CASE

Clinically, Dr Muirhead presented a typical, slowly progressing case of chronic Addison's disease with pigmentation, marked asthenia, intestinal discomfort, and low blood pressure He gave a questionable history of renal tuberculosis, but tuberculosis was not borne out at operation, a right side nephrectomy being performed in 1918

Subsequent to the nephrectomy, gout developed, the patient suffered from typical attacks of great severity, involving the metatarsophalangeal joints associated with high level of uric acid in the blood Both the gout and blood uric acid responded promptly and permanently to a low purin diet It is of interest to speculate on whether or not the removal of the kidney was a factor in the increase of the blood uric acid and in the development of gout

The patient's improvement under treatment with epinephrin and the whole suprarenal gland during the first visit to Rochester, and after his return home, was striking objectively as well as subjectively Rectal injections of epinephrin proved effective for a considerable period, although they were finally discontinued because of tenesmus Glandular therapy was of unquestionable value in the relief of asthenia and of gastro-intestinal discomfort, and resulted in a temporary clearing up of pigmentation. For a time at least, it also checked the general course of the disease

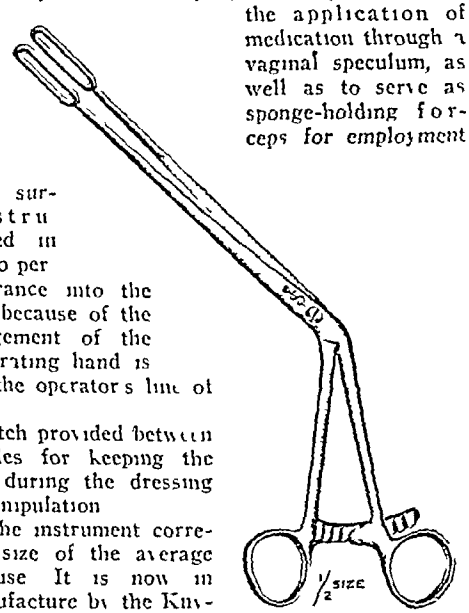
Although the results were only temporary, they were almost miraculous Such definite relief of symptoms in the chronic form of the disease justifies a thorough trial of such measures in other cases of Addison's disease

Clinical Notes, Suggestions, and New Instruments

NEW ANGULAR UTERINE DRESSING AND SPONGE-HOLDING FORCEPS

ALBERT M CRANCE M D, GENEVA, N Y

The instrument shown in the accompanying illustration was designed chiefly for use as sponge-holding forceps for the application of medication through a vaginal speculum, as well as to serve as sponge-holding forceps for employment in gynecologic surgery The instrument is shaped in such a way as to permit direct entrance into the speculum, and, because of the angular arrangement of the handle, the operating hand is entirely below the operator's line of vision



New angular uterine dressing and sponge holding forceps

There is a catch provided between the ring handles for keeping the forceps locked during the dressing or sponging manipulation

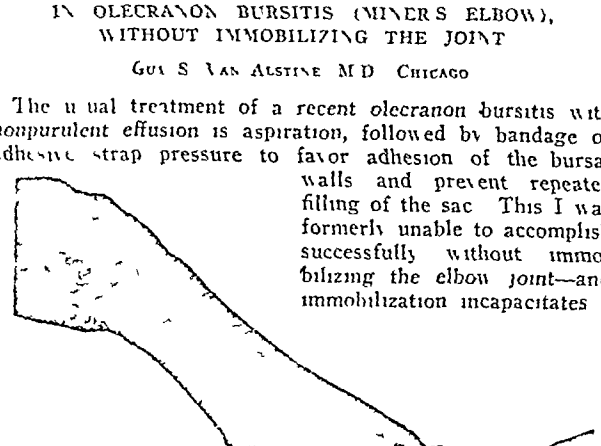
The size of the instrument corresponds to the size of the average speculum in use It is now in process of manufacture by the Kny-Scheerer Corporation

Schmrel Building

A METHOD FOR MAINTAINING PRESSURE OVER ELBOW IN OLECRANON BURSITIS (MINER'S ELBOW), WITHOUT IMMOBILIZING THE JOINT

GUY S VAN ALSTINE M D CHICAGO

The usual treatment of a *recent olecranon* bursitis with *nonpurulent effusion* is aspiration, followed by bandage or adhesive strap pressure to favor adhesion of the bursal walls and prevent repeated filling of the sac This I was formerly unable to accomplish successfully without immobilizing the elbow joint—and immobilization incapacitates



Bandage cut from inner tube of automobile tire

The accompanying reproduction of a photograph illustrates a bandage cut from an automobile inner tube which, I find, will maintain sufficient pressure to bring about obliteration of the bursal sac without greatly inhibiting the joint action With this device my patients have been able to continue their usual occupations while under treatment This treatment is not suitable in old chronic cases with thickened, fibrous sacs, or in acute suppurative bursitis

PRODUCTION OF BILE PIGMENT WITHOUT INTERVENTION OF THE LIVER

The question of the origin of the bile pigments has played an important part in the interpretation of disorders of the liver. Until lately this organ has been *held primarily responsible for the appearance of bilirubin* and its companion pigments, whether in the bile which represents their normal habitat or in the blood and tissues wherein their occurrence is essentially an abnormality. The generally accepted hypothesis has been that the pigments responsible for the characteristic discoloration in jaundice are manufactured in the liver, whatever the cause of their absorption into the blood may be, and there is agreement in regarding the blood pigment, hemoglobin, as the precursor of the bile pigments.

Icterus may occur not only after obstruction to the outflow of bile, but also following hemolysis not associated with interference with the hepatic secretion. It is, of course, readily conceivable that in the latter case the liver cells are nevertheless concerned in the genesis of the bile pigment which happens to be returned directly into the blood stream instead of the biliary capillaries. Types of hemolytic icterus have been described in which the kidneys excrete bilirubin without the bile salts which might be expected to accompany it if the abnormality represented a mere perversion of bile production. Consequently, it has become more common in recent years to assume that in such cases of "dissociated" icterus—that is, bile pigments present in blood and urine unaccompanied by bile salts—the liver does not seem to be concerned.

In his lecture before the Harvey Society at New York in January, Whipple[1] reviewed anew the evidence that true bile pigment can be formed from hemoglobin within the body or by other than liver cells. Whipple and Hooper[2] showed that this transformation could be effected within two hours in the blood stream of the head and thorax with complete liver exclusion. The same workers[3] showed that hemoglobin can be transformed into bilirubin in the serous cavities within a period of twelve hours. It is regarded by Whipple as probable that the vessel endothelium and Kupffer cells are concerned in the vascular reaction.

Additional support to the view that hemoglobin can be changed to bile pigment and other substances, quite apart from essential liver cell activity, has lately been furnished[4] at the Massachusetts General Hospital, from a study of patients exhibiting paroxysmal hemoglobinuria. In a particularly instructive case, intravascular hemolysis was produced in a very restricted portion of the circulation. Thus, the products of hemolysis were completely isolated from the influence of the general circulation or of any of the organs of the body. Free hemoglobin was liberated, and reached its greatest concentration in the plasma in twenty minutes. Although still completely isolated, the free hemoglobin rapidly diminished in concentration. Accompanying this reduction in hemoglobin concentration there was a marked increase in the bilirubin content of the plasma, as indicated by a positive Gmelin test and by a change in color of the plasma from a reddish yellow to a dark golden yellow. As no bile pigment had been introduced into the blood of the isolated arm circulation at any time, it is evident that the free hemoglobin had undergone a transformation in the bilirubin in the local blood vessels, capillaries and tissue spaces. It was concluded that such experiments suggest that a large part of the transformation of hemoglobin into bilirubin could occur normally in the blood vessels. Possibly the greater portion of this change takes place ordinarily in the blood vessels of the liver because of the vascularity of this organ. If the catabolism of hemoglobin can actually be accomplished without the intervention of the hepatic tissue proper, the story of pigment metabolism in the body will need to be rewritten.

THE LYMPHATICS IN TUBERCULOSIS

In the conventional discussions of the physiology and pathology of the body, only scanty attention is usually paid to the lymphatic system. This is perhaps due to the fact that the latter does not obtrude itself so conspicuously as does the blood vascular system for observation, in part it is due to the lack of information regarding the "middleman" between the blood and tissues, and the spaces within which the lymph is confined. From the standpoint of nutrition and cellular function, the significance of the lymphatic system becomes emphasized by the fact that in no part of the body does the blood come into direct contact with the tissue cells, for it is confined in vessels with distinct

walls The exchange of materials—food products and waste substances—goes on through the intermediation of extravascular fluids Some of these are contained in the tissue spaces, others in what is now regarded as a closed system of vessels comparable with the blood vessels In fact a recent writer [1] has summarized the present-day belief by pointing out that the tissue spaces are not continuous with the lymphatics, any more than they are with the blood capillaries, indeed, in many situations in the body there are no lymphatics, yet tissue spaces and tissue fluids exist in them The term "lymph," on this view should be restricted to the fluid in the lymphatics It may or may not be the same as the tissue fluids we are further told, but until their identity has been established it is preferable and more exact to speak of tissue fluids and of lymph, regarding them as distinct from one another Lymphatics are associated with the connective tissues and are much more limited in their distribution in the body than are blood vessels

Soluble and diffusible matter finds no difficulty in gaining entrance into the circulation and thus becoming readily distributed in the organism On the basis of the views expressed above, however, the lymphatics seem to be especially concerned with the intake and transport of undissolved particles of which bacteria afford a typical example They may find their way into the lymphatics through the agency of ameboid phagocytic cells which can penetrate the walls of conducting systems Once in the lymphatics, however, the path of progress is filled with numerous obstructions in the lymph glands

In a report to the Medical Research Council in Great Britain Herring and MacNaughton [1] of the University of St Andrews have called attention anew to the function of the lymph glands, particularly in relation to the tubercle bacillus In its early stages in the body, the fate of this micro-organism is much the same as that of other insoluble particles The lymph gland is an extremely efficient filter and allows solid particles to traverse it only when they arrive in too great numbers at a time or when the gland has become disorganized The British investigators point out anew that the lymphocytes of the lymphoid tissue act as a mechanical barrier against the escape of the particles, and eventually the barrier is made more complete by the appearance in it of fibroblasts and the formation of fibrous tissue The foreign material is firmly enclosed, while the lymph sinuses are left open for the free passage of lymph

In the case of tubercle bacilli some of which may be destroyed in their encounter with body cells, their multiplication in a tuberculous focus in the lymph glands gives rise to an added complication through the possible production of soluble toxins As Herring and MacNaughton further conclude, these easily transported products set up an intense lymphocytosis in other glands through which the lymph passes The toxin or other chemotactic substance precedes the bacilli and renders the glands less pervious to them by narrowing the lymph sinuses and filling them with lymphocytes The physiologic mechanism generally considered protective we are further assured, may cease to be so and may actually further the spread of the disease What protection is afforded appears to be merely a mechanical one and the gland in which the organisms are successfully immured by fibrous tissue, when this does occur may remain a source of further infection if for any reason the protective barrier is broken down

REGURGITATED ECTOPLASM

Medicine is concerned with phenomena which involve the fundamental sciences of physics, chemistry, biology and psychology These departments of human knowledge do not represent a finished development, they are subject to the changes which progress in inquiry always brings about and to the growth which is the glory of learning Scientific discovery and sober reflection are forces which pave the way to advancement, there is nothing occult or mystical about them, they are natural rather than supernatural activities Now and then the observer encounters phenomena which seem to defy interpretation on the basis of the known laws of the sciences Under such circumstances there is often an almost irresistible temptation to ascribe the seemingly inexplicable to some unique "superscientific" potency In former centuries, 'animal spirits" were called on to assume responsibility for that which could not be explained by current knowledge Subsequently, within the recollection of many among us, the physiologic activities that failed to admit of ready interpretation in harmony with the biologic sciences were designated as "vital"

"Vitalistic' explanations, implying reaction beyond the pale in which the laws of physics and chemistry apply in the body, have long been popular The history of learning ought, however, to furnish adequate warnings of the unwisdom of venturing explanations which call for mere faith without demonstration Many of the miracles of ancient days—and even of modern times—have been dissipated by the advance of knowledge The rise of bacteriology has meant the fall of much superstition and ignorant belief A trained mind will not say "I cannot know" when, in reality, it intends to convey the information, "I do not know"

In addition to the natural mystery which attends the limitations of knowledge in many fields of science—mystery such as that of the nature of heredity, the forces of absorption and secretion, the regulation of growth and development—there are conjured mysteries

which boldly flaunt their marvels into the faces of a receptive world Occult science—an obvious misnomer—has long been used not only to secure homage from the gullible but also to attempt ridicule of the devotees of that organized common sense which true science represents Recently "spiritism" has again come into the limelight as an instance of present-day credulity Instead of mysterious levitation, the latest phase of the old scheme of transcending the known types of action, physical or psychic, consists in evoking manifestations of the ectoplasm" Those who have the "will to believe" can supposedly observe the mediums giving "temporary immaculate birth to fugitive parental matters without organic growth and not capable of permanent life, but nevertheless capable of immediate temporary formations subject to tremendous exertions of imagination and will power expressed by the medium herself or through the medium by others present"

Here is something to tax the ingenuity of the incredulous scientist, we are assured Manifestations of no mere protoplasm, the physical basis of life, but of a subtle ectoplasm of intangible tangibility and of outside origin And have not great minds admitted seeking this remarkable substance, which is not living and yet takes the form of living matter in the indispensable cabinet? But the ways of the scientific skeptic are inquisitive A group of psychologists and physiologists in Paris have attended the seances of an ectoplasm specialist and discovered not some rare inexplicable emanation issuing from the medium's person but merely a substance coming from the mouth after a convulsive movement characteristic of emesis And so the mystery of the ectoplasm is unmasked "This formidable twentieth century biologic miracle," says the New York *Times* the three wise men of the University of Paris dare to call a vomit!

CONTINUE THE EMBARGO ON DYES AND DRUGS

Unless prompt action is taken, the people of the United States may soon be paying exorbitant tribute to Germany once more as the price of recovery from disease and of the maintenance of health Caught between the opposing forces in the conflict between the importers of German dyes and American dye makers, now being carried on in the Senate in connection with tariff legislation the synthetic drug industry in the United States, built up as a result of lessons learned during the World War, is threatened with extinction Again German domination of our drug markets looms up as a not remote possibility

Those synthetic drugs found to be of service in the relief of suffering are mostly side products in the manufacture of dyes from coal tar, and their production, on a commercial basis, is not possible except when carried on along with the dye industry With the outbreak of the World War in 1914, commerce with Germany was promptly cut off by the blockade established by her enemies, and we, although then a neutral nation, found ourselves not only without the dyes and essential drugs formerly supplied almost exclusively by Germany, but even without means for producing them Driven by the conditions thus created by the blockade, and later impelled by conditions that resulted from our own entrance into the war, an industry was created within our own borders whereby needed drugs were produced and our civilians and military forces alike supplied with these necessary agents When the armistice was proclaimed, we possessed an infant industry which experience had shown to be necessary to the continued welfare and safety of the American people, and particularly for the relief of the sick

After careful consideration and debate, as a matter of sound economic policy deliberately determined on, and in order that this infant industry might live, a limited embargo was laid against the importation of synthetic drugs and of the dyes with which in their manufacture they were associated, so long as no necessity might exist for importing them Up to the present time our domestic drug supply has been adequate, and as the result of competition among American manufacturers the sick have been able to supply all their needs at fair prices, instead of paying unconscionable tribute to foreign manufacturers The synthetic drug industry now shows signs of growth and of increasing strength that promise sooner or later to make it a substantial factor not only in American prosperity but also in the maintenance of American health and national security

Recently, however, a movement has been initiated that seems likely, if successful, to undo everything that has been accomplished the protecting embargo is to be raised, and the still feeble dye and drug industries are to be protected only by certain proposed tariff schedules Those most familiar with the situation assert that as a result the industries will die, that the duties proposed are inadequate to protect the industries, and that in the present stage of development of these industries no tariff schedule can be framed that will be adequate

No sufficient evidence has been adduced to justify the opinion that American dye and synthetic drug industries will survive if they are thrown just now into competition with the highly organized, war-perfected factories of Germany, operated by poorly paid German labor In the absence of such evidence, it would seem to be folly to take any action that may destroy them The welfare of the people, and particularly the welfare of the sick, requires that the manufacture in the United States of synthetic chemicals for medicinal purposes be protected and built up To that end it is necessary to protect and build up the dye industry, for without it these chemicals cannot be made on a commercial basis In view of the public health aspects of the matter, the

medical profession should make its voice heard in no uncertain terms, protesting against the removal of the embargo. Write or telegraph to your senator today!

Current Comment

VAQUEZ-OSLER DISEASE

A quarter century has elapsed since the attention of clinicians was first clearly directed to a syndrome including erythrocytosis, general cyanosis, and enlargement of the spleen. Vaquez and Osler deserve credit for having brought this unique polycythemia into general notice, and for having dispelled the earlier belief that the malady represents essentially a splenic tuberculosis, hence the justification for the designation Vaquez-Osler disease. Increment in red blood corpuscles is known to occur in the cyanosis of congenital heart disease in which the circulation is too slow, and particularly as a response to the needs of respiratory exchange under conditions of oxygen shortage, such as occurs at high altitudes. Polycythemia under these conditions is a compensatory overproduction of red cells to facilitate the gaseous metabolism of the organism. In the cryptogenic type of polycythemia, however, the stimulus is not oxygen deficiency so that the blood picture does not represent a beneficial response of the blood-forming tissues. The true pathogenesis of the disease remains unknown. In a recent address before the Royal Society of Medicine in London, Vaquez[1] ventured to liken the harmful, cryptogenic polycythemia that bears his name to the overgrowth of the blood, just as solid tissues may develop tumors. Thus, Vaquez's disease might be thought of as a benign tumor of red corpuscles, as leukemia is a malignant tumor of leukocytes. The conception of blood as a distinct tissue is by no means new, and the direction of attention to this view may be productive of helpful studies in the domain of a still obscure malady.

THE TREATMENT OF TYPHOID CARRIERS

In the course of routine bacteriologic examinations of the bile at necropsies, Murstad[2] of the Gade Pathologic Institute in Bergen found typhoid bacilli in a man, aged 58, who had had typhoid fever twenty years before, but who so far as could be learned had not been connected with any epidemics. Numerous typhoid and colon colonies were obtained also from different parts of the liver, from the wall of the gallbladder, and from gallstones in the latter. On the basis of these observations, Murstad studied twenty-two records in the literature of necropsies on typhoid carriers, in eighteen of whom typhoid bacilli were recovered. In nearly all the liver, as well as the gallbladder, contained typhoid bacilli, but it seems that the gallbladder is the principal permanent abiding place of the bacilli, and that if the gallbladder is removed, the bacilli soon disappear from the liver. At any rate, Murstad's analysis of the results of gallbladder operations in twenty-four carriers appears to support this view. In four of eight cases in which cholecystostomy was performed, and in fifteen of sixteen cases in which cholecystectomy was performed, the bacilli disappeared. In Murstad's own experience, however, cholecystectomy failed to eliminate the bacilli from the stools, indicating that a focus or foci of infection persisted somewhere in the liver or the intestinal tract. In view of the fact that the carrier is a most important factor in the spread of typhoid fever, which would become a very much rarer disease than it is even now if carriers could be cured promptly, it would seem that cholecystectomy should be made in carriers for the good of the community as well as for the good of the carriers themselves. Finally, Murstad emphasizes that while the treatment by disinfectants has no effect in the case of carriers with typhoid bacilli in the bile and stools—the so-called fecal carriers—urinary carriers may be sterilized by drugs, the most effective being hexamethylenamin and other members of the formaldehyd group. Vaccine treatment of carriers should be abandoned because it is ineffective.

PROTECT AMERICAN CHEMICAL INDUSTRIES

Every reader of THE JOURNAL is urged to telegraph or to write at once to his senator at Washington, protesting against the removal of the embargo on synthetic drugs and on dyes. One of the benefits that came to the United States as a result of the World War is freedom from German control of its dye and synthetic drug industries. In bringing about that freedom, the embargo has been a most important factor. To remove the embargo now just as these industries are beginning to get firmly established invites disaster, the industries will be overwhelmed by a flood of foreign goods, let loose perhaps for the very purpose of destroying them in their infancy. On behalf of your patients and in the interest of the public health protest against the removal of the embargo and protest now.

SKIN COLORATION IN HEMATINEMIA

The demonstration that abundant intakes of foods relatively rich in carotinoid pigments, such as occur in carrots, tomatoes and other color-yielding plant products, may lead to a retention of carotin in the body sufficient to occasion discoloration of the skin has served to call attention to the possibility of erroneous diagnoses of icterus. Although superficial inspection may temporarily give rise to mistakes of judgment based on mere observation of persons exhibiting carotinemia, the detection of bile pigments by chemical means in the urine can always be depended on to dispel any doubt with respect to jaundice. Schumm[1] of Hamburg has called attention to an added type of brown-yellow discoloration of the skin in cases of marked hematinemia. The occurrence of hematin as an occasional free constituent of the blood has only lately received any considerable recognition. Schumm, who

1 Vaquez: Presse Latine, Jr. 3, 1922, p. 1102.
2 Murstad: Med. Rev. 28, 2, 1921.

1 Schumm, O.: Hämatin als pathologischen Bestandtheil des Blutes, Ztschr. f. physiol. Chem. 97: 32, 1916.

has described a number of cases, regards it as an unquestionably pathologic manifestation which has already been discovered in certain types of intoxication with both organic and inorganic poisons, and in pernicious anemia, malaria, some forms of sepsis, eclampsia and other diseases The possible genetic relationships between hematin and the long recognized hematoporphyrin and bilirubin which may arise under pathologic conditions remains to be elucidated It is important to realize the necessity of being on the lookout for the rarer forms of abnormal pigmentation

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES *NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC*)

ALABAMA

Personal—Dr William H Abernathy, Florence recently resigned as county health officer of Lauderdale County and has been appointed health officer of Pike County and will reside in Troy He succeeds Dr Douglas Cannon, who has been appointed state director of county health work

New Sanitation Rules—New regulations defining the sanitary requirements facilities and conditions under which circuses street fairs county agricultural fairs and similar exhibitions may be held in Alabama were adopted by the state board of health, July 10 Permanent exhibition grounds are to be provided with separate drinking fountains, plainly designated for each race Persons suffering from any communicable disease are prohibited from handling or serving food or beverages on any exhibition grounds——Temporary camps and communities within the state of Alabama must henceforth be conducted in accordance with special rules and regulations adopted, July 10 A community consisting of three or more dwellings of comparatively temporary construction located close to one another, in existence for a period greater than seven days, but not to be occupied for an indefinite period shall be regarded as a temporary community This definition includes mining camps, highway and railroad construction camps, and religious, educational and recreational encampments The territorial limits or boundary of such a temporary community or camp shall extend one-fourth mile (0 4 kilometer) in every direction from any house, cabin tent or other structure which is occupied as a part of such unincorporated community All structures intended for dwellings by human beings shall be of such nature as to furnish protection against undue exposure

ARKANSAS

Fire Destroys Hospital—The Stout Hospital at Brinkley was destroyed by Fire July 27 The loss is estimated at between $13,000 and $14,000

New Nurses' Home at St Vincent's—Construction work has been started on a new three story and basement nurses home for St Vincent s Infirmary at Little Rock The residence is to cost approximately $100,000 and will accommodate eighty nurses Sanders and Ginocchio of Little Rock drew the plans

CALIFORNIA

Personal—Dr Frederick P Gay professor of pathology at the University of California Berkeley has been elected chairman of the division of medical science of the National Research Council——Prof Lewis M Terman has been appointed head of the department of psychology at Stanford University, San Francisco to succeed Prof Frank Angell, who retired recently

COLORADO

Joint Meeting—A special meeting of the Denver Dental Association and the Medical Society of the City and County of Denver was held, August 8, to discuss the antivivisection bill

DELAWARE

New Health Plan—At a meeting of the board of health and representatives of the county medical organizations at Wilmington, a complete set of regulations for the handling of cases of communicable diseases that may arise in the city was approved The purpose of the new regulations is to bring Wilmington in line with the latest practice of the large cities of the country in handling epidemics or single cases of infectious disease, and by having the code in published form to make its methods known to all who are liable to come in contact with them The rules will be printed for distribution

FLORIDA

Near Epidemic of Dengue—According to the reports of the city health officer of Tampa, dengue is rapidly assuming epidemic proportions in that city Eleven cases were reported in two hours, July 7, and the total for that day reached forty victims of the fever One hundred and twelve dengue patients have been reported since the count began

Venereal Disease Control—The fight against venereal disease being conducted by the Florida State Board of Health is proving very successful, it was recently announced There were under treatment in the clinics of the state, during June, 1 199 cases of syphilis in males, 750 cases of syphilis in females, 136 cases of chancroid in males and 13 cases of chancroid in females, making a total of 3 101 persons under treatment during the month This work is part of the work of the division of venereal disease, which is one of the divisions of the bureau of communicable disease of which Dr George A Dame is director There are at present twelve clinics in the state for the free treatment of indigent cases and for a graduated fee in cases of the nonindigent who are not able to pay a full fee Four of these clinics are conducted by physicians employed by the Standard Lumber Company

GEORGIA

Child Hygiene Act Adopted—A resolution creating a state agency to cooperate with the federal department of child hygiene for the expenditure of $19,530 apportioned Georgia under the provisions of the Sheppard-Towner Maternity Bill, was adopted July 18, by the Senate

ILLINOIS

Personal—Dr Otto E Fink, Danville, has been appointed visiting oculist and aurist to the Danville Branch of the National Home for Disabled Volunteer Soldiers

Hospital News—A $250 000 addition to Our Saviour's Hospital at Jacksonville is being completed An additional $50 000 is now being secured to purchase equipment and furnishings for the hospital——The cornerstone for the Eastern Star Home for the Aged to be erected in Rockford, was laid recently at appropriate exercises The new building is being erected at a cost of $175,000 and will be completed by September 15——Plans have been completed for the new hospital to be erected at Harrisburg at a cost of $75,000

Conference on Diphtheria Control—August 2, about thirty public health officials, including the director of the state department of public health, the health commissioner of Chicago and a number of local health officers met and discussed diphtheria control measures Under the chairmanship of Dr Herman N Bundesen the deliberation centered particularly around the use of toxin-antitoxin as an immunizing agent and the question as to whether or not a state-wide campaign in favor of general inoculation against diphtheria among children of preschool age would be advisable

Successful Milk Conference Held—Satisfactory progress was made at a conference held in Chicago August 1, between more than 100 representative Illinois milk producers and milk dealers and public health officials in about equal numbers Those present unanimously adopted a motion favoring a state law that would guarantee perfectly safe milk supplies for municipalities They also accepted with slight alterations an ordinance drafted and presented by the state department of public health as a model ordinance for adoption generally by municipalities This ordinance was drawn up with the idea of especially stimulating pasteurization As a means toward bringing about practical results from the conference the permanent chairman, Dr W A Evans, Chicago, was authorized to appoint three committees The duty of one will be to edit and publish the minutes of the meeting, of another, to promote the adoption of the ordinance by municipalities, of the third, to render in the course of one or two years a report on practical legislative measures

INDIANA

Typhoid Fever Compensable—The appellate court of Indiana has decided that typhoid fever contracted by an employee through drinking impure water furnished by the employer, is an injury" by "accident arising out of and in the course of the employment" under the Workmen's Compensation Act, and as such is compensable

IOWA

Eradication of Hay-Fever—Under the direction of Prof Clifford H Farr of the botany department of the University of Iowa, Iowa City, the city officials and residents have cooperated in a campaign to rid the city of ragweed

Hospital News—The detention hospital of LeMars was recently destroyed by fire——A new tuberculosis hospital was recently opened for Henry County in Des Moines——The new Military Surgeons' Club of Iowa has approved plans for building a memorial hospital in Fort Dodge in honor of the physicians, nurses and enlisted men of the medical service who lost their lives during the World War Plans call for a $40 000 structure, which will be started as soon as funds are available, which it is expected will be raised by popular subscription The hospital would be used during camp periods of national guards and by the general public in time of disaster or epidemic——The new east wing of the Jennie Edmundson Memorial Hospital Council Bluffs, erected at an approximate cost of $200,000 was formally dedicated recently It is four stories high with an observatory attic and a physicians' clinic room overlooking the surgical laboratory below Dr Donald Macrae leader of the Mobile Hospital No 1 in France, during the World War, delivered an address——The Allen Memorial Hospital, Allen Heights is rapidly progressing, and it is expected to be finished this year——A new $120,000 building will be erected at St Luke's Hospital Mason City

KENTUCKY

Hospital News—A new tuberculosis hospital will be erected at Waverly Hills in the near future——A new hospital will be erected at Maysville at an estimated cost of $35 000——The Harrison Memorial Hospital, Cythiana, was dedicated, July 4——A new hospital is practically completed at Whitesburg

LOUISIANA

New Dean for Tulane—The board of administrators of Tulane University, July 31 elected Dr Charles C Bass as dean of the School of Medicine

New Baptist Hospital—The Home Mission Board of the Southern Baptist Association has been instructed to build a general and research hospital in the city of New Orleans, to cost approximately $2 000,000

Appeal for Hospital Funds—The Charity Hospital, New Orleans, has requested a bond issue of $300 000, which Governor Parker vetoed as unconstitutional after the bill had passed the Senate and the House, recently The money is needed for an additional building for interns and also for nurses The interns' home was erected thirty-three years ago to house eighteen interns There are now thirty crowded in, and others have to seek accommodation elsewhere The nurses' home is seventeen years old and was originally intended to accommodate 102 nurses The minimum requirement now is space for 200 nurses

Smallpox in Oil Camps—The existence of smallpox in oil regions of Louisiana has caused Dr Dowling of the state board of health to issue warnings that all persons whose business takes them to these regions should be vaccinated One hundred and fourteen cases occurred at Haynesville it was stated in the report of communicable disease for the week ending July 22 Dr Dowling states that for several months, despite all efforts smallpox has been increasing in the northern section of the state In the oil field regions, owing to the fact that there has been such a rapid increase in the population that sanitation cannot keep pace with it typhoid is very prevalent

Course for Physicians in Physical Training—Our German exchanges mention that this week there is being held at Berlin a graduate course on the importance of physical exercise It was organized by the committee in charge of medical graduate courses and the German Hochschule fur Leibesubungen, and is in charge of Prof A Bier The aim is to give physicians a better insight into the nature and system of gymnastic exercises and sports As these can be learned best by actual experience the course includes three hour exercises daily, besides three or four hours of lectures The course is to last thirteen days and the expense for the whole with board and lodging is stated to be 955 marks

Medical Work in Siam.—Dr George McFarland emissary to the United States from the king of Siam, has been on a short visit to his relatives in this country and will return to Siam in October Dr George McFarland who is a graduate of the College of Physicians and Surgeons Baltimore is dean of the Royal Medical College, Bangkok (University of Chulalongkoran) A five-year course in medicine is given with a sixth year in internship and practical experience at the college which at present has 250 students Dr McFarland states that a flying service is attached to the medical department of the university in Bangkok, which is named after the late king, who donated the land and endowment fund Dr McFarland is not a missionary to Siam but a representative of the Siamese government

University News—Sir George Murray recently opened the new Darling Building at the Medical School of the University of Adelaide, Australia This building will serve the department of the fundamental sciences of the medical school as formerly there was insufficient accommodation for the teaching of anatomy physiology and pathology The family of the late John Darling contributed £15,000 toward the erection of the building In declaring the building open, Sir George gave an account of the development of the medical school from the creation of a lectureship in physiology in 1882 to the establishment of a chair of anatomy in 1884, through the period when medical students received the complete course of training, up to the present extension of the school The library of the Darling Building will accommodate the library of the South Australian branch of the British Medical Association, as well as the medical library of the university

Three Years of the Swedish Antivenereal Disease Legislation—The *Hygienisk Revy* devotes a long editorial to the workings of the law which has now been in force for three years The number of cases of venereal disease has been reduced by 60 per cent during this period in Stockholm and by 40 per cent for the whole of Sweden Dr Karl Marcus in announcing these figures remarked that the legislation is not altogether to be credited with this improvement, as the hard times have something to do with it During periods of prosperity, the venereal diseases increase in frequency, and they drop off during financial depression However, during this three year period, the reduction in the number of cases of venereal disease at Copenhagen and at Christiania has been only 10 per cent The editorial adds that both Norway and Finland are planning similar legislation, and even in Germany, parts of the Swedish law have been taken as a model This law was discussed with great interest at the Red Cross Conference at Copenhagen in May The objection is made to the law that it does not suppress prostitution, but the editorial reiterates that this is a social, not a medical question, and the law is planned from the medical standpoint Venereal disease in sailors is a question which demands international cooperation the editorial adds In Sweden the seamen get free medical attention but this is not the case everywhere

Graduate Courses in Western Europe—Nearly all the European countries are busily organizing graduate courses in all kinds of specialties, in hygiene, general medicine, diagnosis, etc, and they all welcome American physicians with special cordiality It is impossible to call attention to all the courses separately, and the American University Union has been founded partly to supply information in regard to graduate and undergraduate work for all applicants The office in England is 50 Russell Square, London and Prof J W Cunliffe of Columbia University, New York is the secretary of the board of trustees in the United States The office of the continental division is at 1 rue de Fleurus Paris There is also a university bureau of information for medical affairs at Paris which is open every afternoon with an English speaking official in charge 65 rue de Miromesnil Paris A practical guide has been published containing the data useful for medical men, and information as to special graduate courses at any time is freely available on demand Italy also is offering numerous courses, and Germany has a regular well established system for graduate courses which brings them within the reach of every practitioner in the country at some time during the year The Vienna graduate courses have been mentioned recently in the correspondence department Prof F Widal begins September 4, at Paris two courses of ten lectures each on methods of clinical exploration applied in the diagnosis of diseases, especially of the kidneys and liver Each course is limited to twenty-five, and the price for ten lectures is 100 francs

Personal—Dr N Bishop Harman London, has been elected a corresponding member of the Societe nationale des sciences naturelles et mathematique de Cherbourg, in recognition of his researches into the origin of the facial musculature—Prof George H F Nuttall of the University of Cambridge, England, has been elected a corresponding member of the Societe de Biologie, Paris, and of the Society of American Bacteriologists—Dr Alexander Mills Kennedy, who was appointed professor of medicine in the Welsh National Medical School last October, has been elected dean of the school to succeed Prof David Hepburn—Sir William Thorburn Sir Charles A Ballance and Dr R P Rowlands have been elected fellows of the Royal College of Surgeons of England—Dr Legry, professor of anatomy in the Paris School of Medicine, has been elected a member of the Academie de Medecine at Paris to succeed the late Professor Ranvier—Prof L Devoto has been placed in charge of the Italian Antonio Devoto Foundation which has a 10 000,000 liras fund to train the public in hygiene and prophylaxis of occupational affections An asylum for children and a colony for study and work are also planned and a large property has been acquired at Chiavari for the purpose Some scholarships for college work and graduate study are also to be offered to Argentine undergraduates and graduates—The seventieth birthday of Dr S Goldflam, one of the leading neurologists and alienists of Poland, was celebrated by the profession there recently The *Informateur* states that a special volume of "Neurologie polonaise" was dedicated to him on this occasion

Deaths in Other Countries

Dr W H Banner Robinson, surgeon-general with the government of Bengal, India—**Dr K McMillan,** of typhus fever while attending his patients, at Hamkeung Korea—**Major-Gen W F Stevenson,** R A M C, England, formerly professor of clinical and military surgery at the Royal Army Medical School, author of "Wounds in War, the Mechanism of Their Production and Their Treatment", July 7, aged 78—**Dr A N Davis,** superintendent of the Devon Memorial Hospital, England, June 29, the day preceding his intended retirement—**Dr Deiters,** director of the Psychiatric Institution at Duren, aged 54—**Dr S S Ostenfeld,** assistant to the orthopedic clinic at Copenhagen—The *Policlinico* reports the death of **Dr C Cavazzeni** and **Dr Ricci** of Bergamo both killed in an automobile accident—**Dr J Drivon** of Lyons, aged 80

Government Services

Changes in Public Health Service Appointments

Changes in the heads of the various divisions of the U S Public Health Service have been announced by Surgeon-General Cumming Surgeon F C Smith has been detailed as Assistant Surgeon-General in charge of the division of marine hospitals and relief, and Surgeon B J Lloyd has been detailed as Assistant Surgeon-General in charge of the division of sanitary reports and statistics of the bureau Assistant Surgeon-General C H Lavinder has been relieved as Assistant Surgeon-General in charge of the division of marine hospitals and relief and has been assigned to the position of executive assistant in the office of the Surgeon-General Assistant Surgeon General B S Warren has been relieved from duty as Assistant Surgeon-General in the bureau and assigned as director of the second regional district, at Baltimore

New Medical Reserve Units

In accordance with the scheme of organization of medical reserve units, the following new hospitals have been organized

Evacuation Hospital No 21 (St Anthony s Hospital Terre Haute Ind)

General Hospital No 55 (Creighton University College of Medicine Omaha Neb)

Red Cross Loans for Blinded Ex-Service Men

At the meeting of the executive committee of the American Red Cross in June the sum of $12 000 was made available for making capital loans to blinded ex-service men during the fiscal year ending June 30, 1923 These loans are for the totally or partially blinded soldiers who wish to establish themselves in a small business The loans will be subject to the following conditions

1 No loans shall be made unless the man s progress has been satisfactory to the officer of the U S Veteran s Bureau who has had immediate supervision of his training

2 No loans shall be made until a thorough investigation of the business venture has been made by a responsible agent of the bureau who is familiar with the nature of the business which the man desires to establish

3 No loans shall be made without the approval of both the director of the Evergreen School for the Blind and the fiscal agent of the American Red Cross if the man has received his training at Evergreen or without the approval of the supervisor for the blind and the fiscal

agent of the American Red Cross stationed at Evergreen if the man has received his training elsewhere

4 It is the understanding that in every case in which a trainee has been aided to establish himself in a small business venture with the aid of a loan he will be given adequate supervision and follow up and that for the first year he will be visited by an agent of the bureau familiar with the training of the blind and with the nature of the business at least once in three months

Spread of Cocain Traffic

About a year ago Dr Courtois-Suffit, a medicolegal expert, presented, in collaboration with Dr Rene Giroux a communication to the Academy of Medicine on the inadequacy of the law of July 12, 1916 in connection with the campaign against cocainomania (THE JOURNAL, Aug 20 1921 p 633) In the meantime, Suffit and Giroux have pursued still further interesting investigations on the traffic in cocain The number of arrests on the charge of trafficking in cocain has increased four-fold from fifty three in 1916 to 212 in 1921

In order to escape the vigilance of the police, traffickers in cocain have of late, invented a number of schemes some of them quite ingenious They sell the drug in counterfeit wristwatches, medallions, or powder boxes with a double bottom Some go about as truckers, selling tangerines containing a supply of cocain, others offer for sale artificial flowers which have within their petals a tiny pouch enclosing 2 or 3 gm of the drug Some persons engaged in the traffic do not carry with them a supply of the drug but seek out customers while they are trailed by a partner who distributes the drug Sometimes too, the cocain is offered for sale, payment is made in advance and the place where the drug is concealed is made known It may be behind a drinking fountain under the sidewalk or under the seat of a parked taxicab Employees on through express trains and soldiers with the occupation troops in the Rhine Province are said to be guilty of taking part in the traffic The drug is transported by aeroplane as well as by mail, coming in this case, chiefly from Morocco, Spain and Holland To facilitate distribution, important depositories have been created throughout the provinces A firm of exporters and commission brokers, who were supposed to be dealing in textiles was in reality engaged in wholesaling German cocain The enormous profits realized constitute a very serious temptation The present purchase price of a kilogram of cocain is about 1,300 francs ($106 60) A small package of cocain, containing 1 gm, is usually sold for from 20 to 30 francs Thus the traffickers and middle men have about 20 000 francs ($1,640) to divide between them for every kilogram of the drug they sell

Drs Briand and Livet recently pointed out that certain occupations and employments have a tendency to increase the number of cocain addicts For instance among motion picture artists the use of cocain is widespread, owing to the fact that the drug is said to make the eyes more brilliant and more photogenic In order to combat this illicit traffic more successfully a law supplementing the act of July 12 1916, has just been passed According to the terms of this new law the courts shall impose a prison sentence of not less than five years nor more than ten years on persons found guilty of having contributed to the delinquency of others by facilitating in any manner the use of narcotic drugs But in order that the campaign against cocainomania may be effective it is desirable that some form of international understanding on the subject should be reached The spread of the cocain habit in foreign countries, as well, makes it seem likely that it would be possible to bring about the creation of an international commission on narcotics, the most important duty of which would be to draft an international law covering the subject and to provide for its rigorous enforcement Dr Briand and Livet have appealed to the Societe de medecine legale that it draw up such a resolution

In view of the fact that the council of the League of Nations has established a consultative commission on opium, it is to be hoped that the labors of this commission will result in the formulation of a uniform plan by which the trade in narcotics can be controlled adequately

The Therapy of Hypophysial Syndromes

The third Reunion neurologique internationale annuelle recently held in Paris under the auspices of the Societe de neurologie devoted the whole session to the discussion of the therapy of hypophysial syndromes Drs Jean Camus and G Roussy both of Paris presented a report on the pathologic anatomy and the pathologic physiology of such syndromes Dr J Froment of Lyons discussed the clinical and the therapeutic aspects of these syndromes Dr Velter of Paris described the visual affections associated with hypophysial tumors Dr Harvey Cushing of Boston the surgical treatment of tumors of the pituitary body and Dr Beclere of Paris the roentgenotherapy of the hypophysis

Beclere collected forty cases of hypophysial tumors treated by roentgenotherapy The results were excellent from every point of view Beclere regards roentgenotherapy as the preferable treatment of tumors of the pituitary body (especially in acromegaly and giantism), with the exception of tumors of syphilitic origin and syndromes characterized by glandular deficiency

In regard to organotherapy, Dr Froment expressed himself in a reserved manner He recalled that we are not entitled to consider extracts of the pituitary body as the equivalent of products secreted by the hypophysis Some of the effects secured by the injection of such extracts may be due to the presence of quite ordinary substances There is however one syndrome on which injections of an extract of the posterior lobe exert a marked effect namely diabetes insipidus but the action seems to be palliative rather than curative Some encouraging results have been obtained in infantilism and in the adiposogenital syndrome While Froment would not wish to reject organotherapy absolutely he emphasizes that the application of the method should be in a very critical spirit

Preventive Serotherapy in Tetanus in Civil Practice

In a recent number of the *Gazette des hopitaux* Dr Lop of Marseilles raises the question whether preventive serotherapy in tetanus is indispensable in civil practice He refers to a communication presented *during the war*, by Dr Souligoux to the Societe de chirurgie, in which he stated that while he was not opposed to preventive injections of antitetanic serum, he did not think that the disappearance of the tetanus was due solely to these injections, *the principal factor* is the asepsis and the antisepsis, which are applied with more active and more effective substances than at the beginning of the war Of from 1 000 to 1 200 persons injured annually on the streets, wharves or boats or in factories Dr Lop has had, during a long period of years only one case of tetanus which he encountered in a fully developed state the fourth day after the accident The wound was a bruise of the hand The tetanus was treated and cured by the Baccelli method Lop does not use, at the present time the preventive injections of antitetanic serum nor has he done so since 1906, in which year he observed two fatal cases of tetanus in patients who had received preventive

injections of antitetanic serum that had come directly from the Pasteur Institute Among the 15,000 injured persons that he has treated since that time, there were some who presented serious bruises and lacerations Nearly all the wounds were contaminated with grease and dirt A number of the patients were injured at sea, some on boats transporting horses, and often received no medical attention for from four to eight days after injury

No doubt, the war wounded presented a higher degree of susceptibility, as a result of the fatigue and privations suffered during the hours preceding or following the battle, and in consequence also, of the delay, often prolonged in receiving first aid, which was not always adequate in the first-aid outposts Lop is ready to admit that, if he had been at the front, inadequately equipped, he would not have hesitated to resort to preventive injections of antitetanic serum—if for no other reason to satisfy his conscience and out of respect for the results obtained and proclaimed by surgeons whose scientific authority is only equaled by their probity But, farther to the rear, in an evacuation hospital in which approximately the same conditions obtained as in civil practice, he would not have departed from the technic that he ordinarily employs lavage, cleansing with soap, disinfection with alcohol or ether tincture of iodin and hydrogen peroxid extensive debridement prudent sequestrotomy, continuous irrigation with surgical solution of chlorinated soda or with iodin-iodid solution

Death of Dr Jacques Bertillon

Dr Jacques Bertillon director of the army bureau for medical and surgical statistics, died recently, at the age of 70 after a long illness Convinced that the end was near he wrote a short account of his life and sent it to certain journals He was the son, grandson and brother of well-known statisticians, and devoted his whole life work to statistics For a period of thirty years—from 1883 to 1913—he was chief statistician for the city of Paris For more than ten years, he was an instructor in the science of statistics in the College libre des sciences sociales, which he had helped to found in 1895 He published a large number of articles in special journals, more particularly in the *Journal de la société de statistique* (of which society he was president) and in the *Annuaire statistique de la ville de Paris* He assisted in founding the national alliance for the augmentation of the population of France and, with a view to supporting national propaganda for the betterment of the birth rate, he founded the review *La femme et l'enfant* He was a member of the Conseil superieur de statistique and also of the Conseil superieur de la natalite

Dr Gran's Account of Famine Conditions in Russia

Dr M M Gran of Petrograd speaking at the Pasteur Institute of Paris recently gave a vivid account of famine conditions in Russia Dr Gran has been sent out by the Pan-Russian Medical Union to make known to the medical profession in Europe and the United States the gravity of the sanitary situation created by the famine, which presents certain serious dangers for the countries of western Europe According to Dr Gran the number of persons suffering from the famine amounts to 35 million of the population, while the number of persons being aided by foreign governments and charitable organizations (for the most part, American) is only from five to six millions

In connection with this address, the Russian physicians in Paris deposited a magnificent wreath of flowers on the grave of Pasteur and Dr Roux director of the Pasteur Institute spoke of the close relations that had always united Russia's scientists with the Pasteur Institute, to the work of which Metchnikoff had made such important contributions

BELGIUM

Liege, July 24, 1922

Anergic Syphilis

Before the Societe des sciences medicales de Bruxelles, Dr Dujardin discussed recently the question as to whether it is possible to bring about the appearance of allergy in tardy anergic (inactive) syphilis He explained also the indirect procedure by which he had attempted to solve the problem Allergy in syphilis is not effected solely by prepared extracts of spirochetes, it can be brought about by certain ordinary substances for example, the frank intradermal reaction to milk in tertiary syphilis It may be noted in passing that allergy in tuberculosis as well may be produced in the same manner Allergy appears thus to be a quite simple reaction of any organism, for a long time infected, toward certain organic substances that in some respects are similar to the original toxic cause of the infection By successive cutaneous injections of milk, we can secure marked cuti-reactions to milk in a given subject, that is, he develops an allergy for milk The question arises as to whether or not this allergy for milk will produce a specific allergy in an anergic syphilitic While Dujardin cannot as yet assert that such is the case he has noted at least a curious result namely that injections of milk may exert a frank influence on secondary symptoms and it seemed to him that they effected some improvement in tabetic patients, not only with respect to their general condition but also as regards certain subjective symptoms (darting pains) He thinks that this result is sufficient to justify further research, especially in view of the fact that chemotherapeutics seems thus far to have been unable to produce a cure for tardy anergic syphilis (general paresis etc)

Celebration of the Centenary of the Societé royale des sciences médicales et naturelles

The Societe royale des sciences medicales et naturelles the venerable yet perennially young scientific society of Brussels which is a direct lineal ancestor of our Academy of Medicine in that the latter derived its founders from the former celebrated, June 22 with special ceremonies held in Marble Hall the centenary of its foundation Professor Heger gave a vivid and trustworthy account of the founding and early activities of the society bringing out the fact that it took up and continued the work of the old Societe de medecine, de chirurgie et de pharmacie, which was established in 1795 following the fall of the Austrian regime After in existence of a hundred years, the society was still giving abundant evidence of its vitality Men succeed each other,' he said historical events pass across the stage and fall into oblivion, but institutions which are the outgrowth of high thoughts and lofty principles persist and must persist if their purpose is noble and upright, not contaminated by selfish interests and promoting only the good of the general public"

The Goiter Problem in Belgium

The results of Dandois inquiry into the incidence of goiter in Belgium, which he recently laid before the Royal Academy have a suggestive interest His report shows that there are very few cases of goiter in Belgium, and it is interesting to study in a nongoitrous country the geographic incidence of the disease It appears that the results are not identical with those obtained in countries in which the disease is widespread

Dandois divides the country into three regions, basing the distinction on the relative number of cases of goiter found in each as shown by the examination of recruits Lower Belgium, made up almost entirely of plains, presents an insignificantly low incidence of goiter Middle Belgium, for the most part a country of plains, but which has, scattered

here and there small areas of rocks and wooded hills shows an appreciably higher incidence than Lower Belgium, but the number of cases is still comparatively small The third area, the provinces of Liege, Luxembourg and Namur, where the earth's surface is uneven rocky and cut up with mountains and valleys with winding rivers, furnishes, with a total population of not much more than a million, relatively high figures, there having been 108, twenty six and seventeen exemptions, respectively, in the three provinces

This inquiry is only the prelude of a statistical study which will furnish valuable information for the time is propitious in view of the fact that the project of distributing throughout the state a high grade of drinking water seems about to be realized and the further fact that the economy of the distribution of goiter poison is being studied more and more and that in all probability drinking water will be found to be the principal intermediary agent

Annual Meeting of the Belgium Surgical Society

The annual meeting of the Societe belge de chirurgie was held this year at Liege, under the presidency of Professor Willems A large number of surgeons of Brussels Antwerp and Ghent gathered in the hospital services of Liege and listened to the discussions There were three main subjects studied

ARTICULAR TRAUMATISMS OUTSIDE OF FRACTURES

Albert of Liege set forth the surprising results secured by immediate active mobilization in traumatisms of the knee It was first applied to the treatment of hemarthrosis Willems method has completely revolutionized old therapeutic methods and changed for the better the prognosis in a large proportion of articular lesions The technic and the results are very simple In simple traumatic hydrarthrosis, the treatment is the same and the results are also perfect The essayist reported also the excellent success secured by meniscectomy in cases of contusion or of luxation of the semilunar cartilage fifty cases of which have been treated by Willems

The method has been applied also to purulent arthritis, formerly much feared All forms of incision and all means of drainage that had been tried hitherto had failed miserably *Mobilization begun at the start, while the infection is still* confined to the synovial membrane, by a continual *brassage*, rids the joint of its purulent contents When the treatment is instituted in the very beginning, patients suffering from purulent arthritis in full evolution will preserve in the injured member a musculature scarcely inferior to that of the corresponding sound member

AMPUTATIONS AS DETERMINED BY THE TYPE OF PROSTHESIS TO BE WORN

Martin and Neuman discussed the level of the amputation the choice of technic and postoperative treatment In leg amputations they prefer the Anten method with lateral flaps They discredit the classic amputations of Chopart Pirogoff and Lisfranc They assign great importance to providing patients with temporary prosthesis soon after the operation, and recommend early *mobilization for amputation* stumps Some of their conclusions follow

The development of orthopedics, as far as supplying prosthetic apparatus for patients is concerned has had a notable influence on the surgical technic of amputations It is clearly evident from the experience gathered during the war that a surgeon who is called on to perform operations should keep in close touch with an orthopedist who is acquainted with modern methods of treatment and with modern types of prosthesis The complete recovery of this class of wounded demands the close collaboration of the surgeon and the orthopedist It is desirable, for the sake of those who have had limbs amputated that the large surgical services recognize the necessity of this collaboration Our large sanitary units both official and private, should have an orthopedic service attached to their formations, at least for the orthopedic treatment of stumps and the early provision of prosthetic apparatus It would also be desirable for such formations to keep in constant touch with an institution capable of furnishing prosthetic apparatus constructed on definite rational and scientific principles

PSEUDO APPENDICITIS

Voucken and Reynders brought out the importance of deep roentgen-ray examinations for the purpose of diagnosing pseudo appendicitis which may take on the various clinical aspects of chronic appendicitis They draw especial attention to cases which owing to the presence of a Jackson membrane or on account of pericolitis, mesenteritis or epiploitis require special surgical treatment

LONDON

(From Our Regular Correspondent)

London, July 14, 1922

Fifth International Birth Control Conference

The fifth international birth control conference, of which the program was given in a previous letter (THE JOURNAL, June 17 1922 p 1907) has been held The attendance was not large but the delegates included visitors from all parts of the world as well as a number of health officers and other representatives of public bodies in this country The president, Dr G V Drysdale said in his address that there had been an embargo on the entrance of science into the social sphere and that their movement was the result of the attempt of the greatest thinkers of the past and present to obtain a really scientific sociology They met for the first time with the knowledge that the whole world was ready for the doctrine of birth control and that East and West were ready to meet on this fundamental human need The terrible economic distress and unemployment which followed the war had forced statesmen to recognize the fundamental truth of the malthusian doctrine, while the great pronouncement by Lord Dawson the king's physician in favor of both a rational and humane sexual philosophy and birth control, had had an effect all over the world

Today all organized opposition to birth control was dead except that of the Roman Catholic church The movement was as greatly concerned with the quality of the race as with its quantity and the latter question was becoming of supreme importance in countries such as Great Britain, America and France, where the birth rate had now fallen to fairly manageable figures but where family limitation had been adopted by the educated and successful sections, leaving the poor improvident stocks to multiply without restraint in their ignorance to the great injury of our race *The movement* had always been deeply concerned with moral ideals, and had always had as one of its chief aims the promotion of sexual purity through general early marriage One of *the most* important objects of the conference was to urge that the public authorities of all nations take steps to secure the provision of hygienic birth control instruction at all hospitals and medical centers where the poor and the diseased congregated *For the whole* of Europe, the birth rate had fallen from 40 in 1876 to 36 5 in 1901 which meant 3,000 000 fewer annual births Australia and America probably swelled the reduction to 5 000 000 This meant that at least 20,000,000 persons had adopted family limitation in one form or another in the forty-five years since the beginning of the movement The reduction of births had saved at least the same number of lives If the process was continued until the average birth rate of the entire world was reduced to 17 or 18 per thousand they would save lives at the rate of 25,000,000 each year,

remove untold suffering from millions of hapless men, women and children, make early marriage and social purity possible, eliminate the struggle for bare existence, improve the quality of the race and delay the economic rivalry which was the most potent cause of international friction and war

Herr Ferch (Austria) said that in his country their opponents, who were supported by large sums of money, were mainly the war profiteers who were dreaming of a war of revenge through an excessive birth rate Dr Goldstein (Germany) deplored the fact that nothing of the conference would be published in the German papers

A resolution was passed expressing pleasure at the achievements of the movement and its extension to the East and calling on the governments of all nations to facilitate extension of birth control knowledge among the poor and unfit in the interests of human welfare race improvement and lasting peace

At the afternoon conference Mrs Margaret Sanger president of the American Birth Control League, presided Mr Edward Cecil said that the root cause of the evil was too much motherhood What chance was there under modern conditions especially in towns for the mother or the children when children were brought into the world at the rate of one a year?

Bernard Shaw on "The Advantages of Being Unregistered"

Mr Bernard Shaw addressed a crowded meeting of the Abernethia Society of St Thomas Hospital on the heretical theme of 'The Advantages of Being Unregistered, which he treated in his usual paradoxical vein It was a serious blow he said to medical prestige that a knighthood had been conferred on Mr Parker the 'bone setter" (THE JOURNAL July 1 1922, p 52) This title was usually given in medicine to the heads of the profession Here it had been bestowed on a man who was not only unregistered but unqualified He had no recognized medical training but "had learned his business' from another bone setter The faculty was inclined to regard such persons as ignorant Unfortunately, they got relatively as many cures as the qualified and often obtained their best results when the latter had failed To the public there had always been a glamor about the unqualified man—probably because he dared to charge more than his qualified rival His popularity had increased so much of late that patients would now frequently run the whole gamut of osteopaths masseurs Christian scientists and psychotherapists before turning to the qualified physician

What was the cause of this waning faith? He attributed it to the narrow mindedness of the general medical council Its main failing was that it consisted entirely of physicians Such a system tended to a medical autocracy and the community for whom the physicians worked had no opportunity of expressing its views on medical organization and conduct The remedy lay in constituting the council mainly of members of the informed public with physicians as assessors Such a body would be in a position to effect several needed reforms in medical practice and education First was the question of admission to the profession It was absurd for any body of men, whether physicians or bottle-washers to say to a man, You shall not enter our profession That was for the general public to say Next came the problem of medical education The most needed reform was lengthening of the curriculum, but this could be compensated for by cutting out certain unnecessary parts of subjects which were taught at present The smattering of science, for instance, in which the medical student was grounded, was unnecessary Medicine was not a scientific profession Yet such was the effect of the so called scientific training that the surgeon tended to regard all disease problems as mechanical, the physician to regard them as chemical, whereas, such problems were vital The curriculum should be lengthened by study of Swedish massage and osteopathy, both of which forms of treatment had proved of value

The Medical History of the Great War

The second of the series of volumes of the medical history of the war has been published It is the first of two volumes on diseases The chapter on influenza is contributed by Dr Herbert French and Sir Wilmot Herringham Much attention is given to the conditions in which pneumonic symptoms developed Delirium and coma occurred in bad cases, but more striking was the number of cases in which they were entirely absent Big strong men, cyanotic, breathing thirty times to the minute and obviously dying, would be fully conscious not realizing their danger in the least until within a half hour of death" In the chapter on cerebrospinal fever, of which there was a formidable epidemic, the importance of overcrowding in the causation is emphasized In the chapter on trench fever, the failure of all forms of treatment, including arsphenamin, is pointed out Prophylaxis—freeing the man from lice—is the important thing The second volume will be concerned with gas warfare, and the medical aspects of aviation and mine warfare It is expected that the whole series excepting the two volumes on statistics and epidemiology will be completed about the end of the year, with the exception of the general histories of the medical services in the various campaigns of the war

The Army Medical War Collection

The valuable army medical war collection of specimens, which has been housed at the Royal College of Surgeons (as described in a previous letter to THE JOURNAL) has now been handed over to the college by the War Office with a sum of $37,500 which is to be devoted in part to a new building for housing the collection while the rest is to be invested with a view to providing an annual sum to help in the maintenance of the new section An important feature of the arrangement is that while the collection will form an integral part of the museum of the college, it will always be at the disposal of the army medical authorities for demonstrations to members of the corps

Industry's Death Roll

The annual report of the chief inspector of factories and workshops for the year 1921 has just been issued During the year 92 565 accidents were reported of which 951 were fatal as compared with 138,773 of which 1 404 were fatal, in the previous year The decline is almost entirely due to the phenomenal inactivity of industry throughout the year, including the prolonged coal strike which resulted in many large iron mills and blast furnaces being completely closed down for a long period These industries are heavy accident producers The number of accidents due to electricity was 322 thirty-two being fatal—a reduction of 20 per cent in the total and of 50 per cent in the fatal cases compared with each of the previous two years There were 230 cases of lead poisoning, of which twenty-three were fatal In 1900 the number was 1,058, of which thirty-eight were fatal There were no cases of phosphorus or mercury poisoning but one case of arsenic poisoning The figures for anthrax were twenty-five cases with six fatalities This low figure is held to be partly due to the inauguration of the government station for the disinfection of wool at Liverpool On the question of hours of work it is stated that, since the forty-eight-hour week has been established, it is a source of satisfaction to find that, when the reduction of hours is continued over a considerable period, output tends in the majority of cases to attain the old level and that the beneficial effects of the increased leisure on the workers are becoming apparent

Marriages

CECIL EDWARD REYNOLDS Los Angeles to Miss Nora Gardner of Hollywood, Calif, July 22

WILLIAM KUYKENDALL to Miss May Rowland, both of Eugene, Ore at Salem July 19

LOUIS FRANCISCO ROSS to Miss Margaret Grubbs Starr both of Richmond, Ind, July 19

DOUGLAS SQUIRE CORPRON, Yakima Wash to Miss Grace Chapman of Redwood Falls Minn July 12

PHILIP L NEWMEYER, Salem Ore, to Miss Ruth Johns of Manila, P I, at San Francisco July 13

CHARLES WILLIS MCLAIN, Gurdon Ark to Miss Joyce Dudley of Hope Ark, June 24

JAMES WESLEY ALDRIDGE to Miss Martha Coffing, both of Covington, Ind, June 15

ABRAHAM GREENBERG Omaha, to Miss Blooma Kogan of Minneapolis, June 14

EARLE BLOODGOOD FOWLER to Miss Barbara Blatchford both of Chicago, August 5

JOSEPH POKORNY to Miss Carrie Wells both of Baltimore July 23

Deaths

Harold Barclay ⊕ New York City, Columbia University College of Physicians and Surgeons, New York, 1899, member of the New York Academy of Medicine, consulting gastro-enterologist to the Portchester Hospital and to St Mary's Hospital, Hoboken, assistant attending physician at Bellevue Hospital New York, served two years in France during the World War with the M C U S Army specialized in internal medicine, died suddenly, July 22, aged 46, at Biarritz France

William D Wolverton ⊕ Pittsdown, N J, colonel U S Army retired, was appointed assistant surgeon in the Army in 1861, served as chief surgeon department of the Columbia Vancouver Barracks, Wash from 1894-1898, was post surgeon at Washington Barracks, D C medical director of the department of the South at Hilton Head S C in 1864, retired in 1898 with the rank of colonel, died, July 20, aged 88

Edward M Eidheer, Chicago, University of Vienna Austria, 1886 formerly expert in the department of agriculture, bureau of chemistry, Austria, member of the Royal Academy of Science of Vienna and the Academy Physico-chemique Italienne, was awarded the gold medal for technical work and scientific merit of the Italian Academy of Palermo died, July 24, aged 60, from cerebral hemorrhage

John E Sylvester ⊕ Wellston Ohio, Medical College of Ohio, Cincinnati, 1876, Bellevue Hospital Medical College New York 1884, formerly president of the Ohio Valley Medical Society, for many years councillor of the Ohio State Medical Association, *for twenty-five years owner and publisher of the Wellston Telegram,* died, July 25 at the Holzer Hospital Gallipolis from diabetes, aged 67

John Nesbit Scott ⊕ Peabody Kansas, University Medical College of Kansas City, Mo, 1897, established the first radiographic laboratory in Kansas City, died July 24, aged 51, as the result of burns received in experimenting with roentgen rays while in practice at Kansas City Dr Scott's right hand was amputated several years ago necessitating his retirement from practice

George Shultze Youngling ⊕ New York City, Bellevue Hospital Medical College, New York 1890, consulting physician to the Manhattan State Hospital and to the Central Islip (L I) Hospital for the Insane member of the American Medico-Psychological Association, died, July 25 aged 60, at his summer home in Patchogue, L I, from uremia

Robert Francis Lawless, Stamford, Conn Yale University School of Medicine, New Haven, Conn, 1907, member of the Connecticut State Medical Society, formerly surgeon for the Pennsylvania Railroad, aged 42, fell dead on the Grand Central Terminal steps, New York, July 27, following an overdose of chloral

⊕ Indicates Fellow of the American Medical Association

Charles P Gerstmeyer, Terre Haute Ind, Medical College of Ohio Cincinnati, 1867, formerly on the staff of St Anthony's Hospital, at one time coroner, health officer and member of the school board of Terre Haute, died, July 27, aged 75 from pneumonia

Samuel W Hixon, Daisy, Tenn University of Tennessee College of Medicine Memphis, 1890, member of the board of education, formerly a member of the state legislature at one time county physician, died July 19, aged 62, at a hospital in Chattanooga

Lyman T Strother, Nowata, Okla, Rush Medical College Chicago 1867, Jefferson Medical College of Philadelphia 1873 member of the Oklahoma State Medical Association veteran of the Civil War, died, July 19, aged 82, following a long illness

William Allin Archer, Houston Texas, University of Virginia Department of Medicine Charlottesville 1869, member of the Medical Society of Virginia, Confederate veteran died, July 6 aged 80, from senility, at the home of his daughter

William Patrick O'Malley, St Paul, University of Minnesota Medical School Minneapolis, 1902, served during the World War in the M C S U Army died, July 6, aged 48 from injuries received in an automobile accident near Shakopee

Francis Wade Hughes New Bern N C, University of Pennsylvania School of Medicine, Philadelphia, 1880, member of the Medical Society of the State of North Carolina died June 28 at the Union Protestant Hospital, Baltimore, aged 65

Samuel N Quillin, Washington, D C, Marion-Sims College of Medicine St Louis 1899, former clerk of the house of the Indiana state legislature, died, May 19, aged 53, at the Sibley Memorial Hospital from diabetes

Hugh N McDonald ⊕ Minneapolis McGill University Faculty of Medicine Montreal Que, Canada 1889, formerly professor of diseases of the chest at the Hamline Medical College Minneapolis, died, July 15, aged 59

Ernest Potter Storey, Minneapolis, Denver College of Medicine Denver 1901 died at the General Hospital, July 21, aged 45 as the result of pistol wounds, presumably self-inflicted at his apartment July 18

Alpheus Henley, Melbourne, Fla, Starling Medical College Columbus Ohio 1865 veteran of the Civil War, served as government physician to the Cheyenne and Apache Indians in 1870 died July 11 aged 88

Archibald A Campbell, Statesville N C, University of Maryland School of Medicine, Baltimore, 1889, formerly county physician of Iredell County, died suddenly from heart disease July 17 aged 66

John Lawson Cameron, Philadelphia, Medico-Chirurgical College of Philadelphia, 1888 member of the Medical Society of the State of Pennsylvania died suddenly, July 26, aged 67, at Ocean Grove N J

Edna Ricker Field Kimball, San Francisco Cooper Medical College San Francisco 1883 formerly attending physician to the Children's Hospital died, July 26, aged 74, from hemorrhage of the bowel

James Ray Brady, Sioux City Iowa State University of Iowa College of Medicine, Iowa City, 1893, consulting physician to the Samaritan and St Joseph's Hospital, Sioux City, died July 18 aged 54

Robert H Lillemann, St Louis, Homeopathic Medical College of Missouri St Louis 1904, member of the Missouri State Medical Association died, July 17, at Barnes Hospital, St Louis aged 52

William C C Freeman, Rock Springs Wyo Trinity Medical College, Toronto Ont, Canada 1893, member of the Wyoming State Medical Society died July 21 aged 54, at Salt Lake City

Susan Elizabeth Crocker, Los Angeles, Woman's Medical College of the City of New York 1874, member of the Massachusetts Medical Society, formerly of Boston, died July 18 aged 87

Charles P Evans, Lehigh Iowa, Bennett Medical College Chicago 1891, died, June 6 aged 59, at the Mercy Hospital Fort Dodge, Iowa, following an operation for perforated duodenal ulcer

Enrique Alberto Rodes, Tampa, Fla, Tulane University of Louisiana School of Medicine, New Orleans 1918 died Jul 11 aged 29, in Havana, Cuba, following a long illness

Milton J Hicks, Jacksonville Fla , Emory University School of Medicine (Atlanta Medical College), Atlanta, Ga , 1860, died, July 21, aged 84, at the home of his daughter in Atlanta

Charles Noble Abbott, Chippewa Falls, Wis , Northwestern University Medical School, Chicago, 1907, specialized in obstetrics, died June 1, aged 52, at a sanatorium in Madison

Frank Wilson Martin ⊕ Lansing, Mich , University of Michigan, Ann Arbor, 1886, specialized in ophthalmology otology, laryngology and rhinology, died, July 17 aged 63

Charles Douglas Miller ⊕ Pottsville, Pa , Jefferson Medical College of Philadelphia 1884, member of the board of pension examiners died, July 24, aged 61, from pernicious anemia

Arthur Eugene White, Baggs, Wyo , University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1890 died, June 22, aged 54, from carcinoma

John Taylor Stewart, Los Angeles, Jefferson Medical College of Philadelphia 1878, member of the Medical Society of the State of California, died recently, aged 72

Enos Hahn ⊕ Leetonia, Ohio, Bellevue Hospital Medical College, New York 1867, died July 8, at Honolulu, Hawaii aged 81, from cerebral hemorrhage

Jesse C Asbury, Greensboro Ga Louisville Medical College Louisville Ky 1886 member of the Medical Association of Georgia died July 3, aged 57

Latzi Szabary ⊕ New Orleans Tulane University of Louisiana School of Medicine, New Orleans, 1877, died July 23 aged 68, from heart disease

R M Kimbrough, Rockwood Tenn University of Tennessee College of Medicine Memphis 1888 veteran of the Civil War, died July 23 aged 66

Joseph H B Adams, Fort Recovery Ohio Physio Medical Institute, Cincinnati 1872, died, July 19 at the Otis Hospital Celina aged 74 from paresis

Albert J Herschman, Milwaukee University of Vienna Austria 1887 died July 31 aged 62 from an overdose of morphin self administered

William D Seeley, Taylorsville, Ky , Louisville Medical College Louisville Ky 1874, died July 14 aged 72 from mitral regurgitation

William D Roussel ⊕ Patterson La , Tulane University of Louisiana New Orleans 1889, died, July 19, aged 54 from heart disease

Charles L Heizman, Colonel U S Army ⊕ San Francisco University of Pennsylvania Philadelphia, 1867, retired, died recently, aged 76

Lucian Tudor Platt, Terryville, Conn University of Pennsylvania, Philadelphia 1869, died recently from lobar pneumonia, aged 76

Oreon Staples Rhodes, East Stroudsburg Pa University of Pennsylvania Philadelphia, 1889, died, July 5 aged 59 from diabetes

Samuel Milton Pratt, Topeka, Kan , Homeopathic Medical College of Missouri St Louis, 1861 died, July 13 aged 86 from senility

J Louis Horsey, Fernandina Fla Medical College of the State of South Carolina, Charleston 1886, died July 13 aged 65

Willis H Park ⊕ Glenwood City Wis , College of Physicians and Surgeons Keokuk Iowa 1884, died, June 27 aged 68

Russell Withers, Annapolis Royal N S Medical Department of Columbia College New York 1865 died recently aged 86

R L Odilon Poliquin, Montreal, Quebec Canada, Montreal School of Medicine and Surgery 1895, died recently, aged 50

Robert Amos Taylor, Spring Valley N Y , Bellevue Hospital Medical College, New York, 1893 died July 16, aged 56

Allen N Gray, Floyd Texas, Baylor University College of Medicine Dallas Texas, 1901, died, June 15, aged 52

H W Booth, Orion Mich , Western College of Homeopathic Medicine, Cleveland 1868, died recently aged 76

Emil J Schwandt, Chicago, Rush Medical College Chicago, 1888 died, August 3, aged 59, from carcinoma

William McChristie ⊕ New York City, Long Island College Hospital Brooklyn 1895 died July 20 aged 56

John Leeson, Cadillac Mich , Detroit Medical College 1869 died July 21, aged 87, from senility

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

THE OWENS ELECTRIC BELT

Another Fraud Barred from the Use of the United States Mails

A P Owens, a peripatetic quack, has been defrauding the public for some time by the sale of an 'electric belt" Owens has advertised from New York City, Buffalo, Miami, Indianapolis, San Antonio and Chicago As long ago as October, 1919, the city of Cleveland, Ohio, which does more, probably, than any other city in the United States to protect its citizens against medical fraud, called attention to the preposterous claims made by A P Owens for his belt

On Jan 14 1922, A P Owens was called on by the federal authorities to show cause why a fraud order should not be issued against him and February 7 was set as the date for hearing the case Owens failed to appear on that date, neither did he send an attorney, but he filed a written answer to the charges together with the advertising literature being used by him at that time in the conduct of his business The solicitor for the Post Office Department, Judge John H

A typical advertisement of A P Owens

Edwards in his memorandum to the Postmaster General, recommending the issuance of a fraud order against Owens, gives the facts regarding this quack in part, as follows

Briefly outlined the scheme conducted by Owens, according to the evidence, consists in placing periodically, advertisements in various newspapers many of them printed in foreign languages, in which he offers for sale through the mails a so-called electric belt which, when worn as directed, is represented to be a cure for various diseases and ailments many of them known to be incurable, while others are amenable to surgical interference only

After getting in touch with prospects through his advertisements he sends them literature containing gross misrepresentations as to the curative value of the belt, and offers terms of purchase which appear to be bona fide After the belt is sold on these terms and the purchaser finds it is worthless or not as represented and returns it Owens refuses to abide by his guarantee to return the deposit 'Without Any Delay Or Question,' but alleges for one reason or another that the terms of the sale have been violated by the purchaser, and insists upon certain conditions being fulfilled, which are impossible of fulfillment'

A typical advertisement of Owens is reproduced with this article Through these advertisements Owens got in touch with his victims Continuing to quote from the memorandum to the Postmaster General

When Owens receives an inquiry respecting his belt he forwards among other literature a stock letter in imitation typewriting setting forth among a number of other representations and promises his alleged 'FAIR AND SQUARE OFFER,' which is as follows

Order one of my powerful No 15 UNIVERSAL MODEL BELTS with OWENS SUPREME POWER BATTERY together with Special Attachment

(if needed) such as Head Bands and Arm or Leg Bands for treating Neuralgia Headache Rheumatism Sciatica etc Send DEPOSIT covering my low catalog price to prove that you are not sending out of mere curiosity You will receive the Belt and whatever you may need with it all wrapped in plain package charges paid You agree to begin immediately and wear the Belt continuously every day or night as directed for a period of TWO MONTHS from the time you take it from the Express or Post Office

At the end of 60 DAYS if you desire to keep the Belt if you are convinced that it has done you more real good than all the drugs and doctors you know of please recommend me to your sick friends But IF after giving the Belt a fair trial as above stated for sixty days you don't want to buy it you agree not to keep it any longer but to return it immediately postpaid to me and if you will do this I will RETURN YOUR DEPOSIT in full without delay or question just as soon as I receive the belt back from the Post Office and the two months trial COSTS YOU NOTHING and as I take all the risk, please be honest with me—don't order unless you NEED THE BELT

"It will be noted that Owens is very emphatic with respect to the matter of alleging that he will return the purchaser's deposit in full 'without delay or question' The evidence shows, however, that purchasers are lucky indeed if they can secure a refund even after considerable bickering It is shown that a purchaser residing in Philadelphia bought a belt from Owens February 11, 1920, under Owens' guarantee that if not satisfied after 60 days use he could return it and his money would be refunded On April 9, 1920, the 59th day the belt was returned as unsatisfactory Owens received the belt on the 60th day The refund was refused because Owens alleged the purchaser had not worn it exactly sixty days On a card mailed to this purchaser on May 8, 1920, Owens states If you can prove to me by a statement from your post office where you mailed the belt that same was mailed not earlier than April 10th, I will return $12 00 to you' The belt was not registered therefore such proof could not be secured and no one knew this better than Owens The foregoing is simply an illustration of Owens methods of evading refunds It indicates his lack of good faith, is directly contrary to his promise to refund without delay or question' and is a part of the general scheme to defraud '

With the letter quoted above Owens also sent certain pamphlets and circulars containing unwarranted and fraudulent claims for the electric belts He also used the orthodox 'scare methods of the medical mail-order faker Solicitor Edwards, in his memorandum, directs attention to this phase of Owens' quackery in these words

"In one of his printed pamphlets Owens has recourse to a method frequently employed by mail order medical concerns namely to scare the readers of his literature into purchasing his belt through dire forebodings of what will happen if prompt action on their part is not taken After warning the reader of the dangers of delay Owens concludes

But for Pity's Sake DON'T DELAY The hospitals and graveyards are full of people who waited for tomorrow to take the treatment they needed today This is no joke remember but A SOLEMN WARNING Send NOW before it IS TOO LATE

Of Owens' tendency to stay in one place only a short time the memorandum says

"Attention is called to the several addresses used by Owens in the conduct of the business At the time of the beginning of the investigation of his business Owens in his advertisements gave Woodcliff Lake N J as his address Investigation at this point disclosed that he had removed to New York When the investigation was undertaken there it was found that a forwarding order was on file showing he had located at San Antonio Texas, and at the same time it was learned that he was doing business at an address in Chicago Investigation begun in Chicago in October 1920 disclosed that Owens had been receiving mail there for about six months at the rate of about 30 letters a day He also was operating under the name of Owens Publishing Company in the sale of alleged obscene pictures and a case has been returned against him relative to that business He was receiving about 20 letters a day addressed to that concern Some time prior to March, 1921, Owens had evidently removed to Miami Florida, as in response to a written communication addressed to him at Chicago by the inspector investigating the case Owens writing from Miami Florida, stated My headquarters is here until May 1st when I expect to leave for Washington D C remaining there a short time then I shall be on the move again, it is doubtful if I return to Chicago for some little time ' Owens plan of flitting from place to place can leave no other conclusion but that this method of evading responsibility also constitutes part of the general scheme to defraud

In summing up the government's case against Owens Solicitor Edwards in his memorandum to the Postmaster General says

"Without reference to the question of the efficacy of electricity in the treatment of disease the evidence in this case shows and I so find that the claims and representations by this promoter for his appliance go far beyond the claims of those members of the medical profession who now recognize electricity as being efficacious in the treatment of some conditions The evidence shows that electro therapists do not employ electric belts in the treatment of disease

The evidence in this case further shows, and I so find that the refund guarantee and so-called free sixty days' trial offer employed by Owens to induce persons to purchase his appliance are not made in good faith, but are designed to work a fraud on the public

I find that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and I therefore recommend that a fraud order be issued against A P Owens"

The fraud order was issued against A P Owens by the Postmaster General July 18 1922

Correspondence

SUGGESTION OF SPIROCHAETA NEOTROPICALIS AS NAME FOR SPIROCHETE OF RELAPSING FEVER FOUND IN PANAMA

To the Editor —Work recently done has proved that the spirochete of relapsing fever in Panama is transmitted by the human tick *Ornithodoros talaje* and that this spirochete is of a distinct species variety or strain from the commonly recognized relapsing fever spirochetes *S obermeieri, S novyi S kochi S duttoni* and *S carteri* Thus far we have called the organism referred to above the spirochete of Panama but now feel that the time has come to give it a specific name *S novyi* is generally recognized as the relapsing fever spirochete of North America Agglutination and immunologic tests demonstrate that the spirochete found in Panama differs as markedly from *S novyi* as *S novyi* does from the Old World strains

The surface of the earth is divided by zoologists into six regions namely the Palearctic the Oriental the Australasian the Ethiopian the Nearctic and the Neotropical regions The boundaries of these regions have been determined in a general way by the localization of genera and species of various forms of animal life It does not seem at all improbable that each of these regions has its own particular species of the relapsing fever spirochete

The Palearctic region which includes all of Europe and the northern part of Asia has *S obermeieri* The Oriental region which includes India Siam the whole of the Malay Peninsula part of China Formosa part of Japan and the Philippine Islands has *S carteri* (India) The Australasian region which includes New Guinea Australia and the Polynesian Islands thus far has no described species The Ethiopian region which includes all of Africa south of the Great Desert and southern Arabia, has *S duttoni* There is also a spirochete credited to East Africa, but Castellani and Chalmers state that recent researches seem to identify it with the West African type There is another spirochete, *S berbera* credited to the northern part of Africa, and to Algeria Tunis Tripoli and Egypt This territory falls within the Palearctic or European region, and Castellani and Chalmers state that immunologic experiments show that this fever is closely related to the European type The Nearctic region which includes all of North America north of the Mexican line except for the southern portion of Florida,

has *S. noguchi*. The Neotropical region, which includes all of Central America and all of South America, has the spirochete of Panama, which we have referred to above. Relapsing fever is not uncommon in Colombia and Venezuela and it is quite possible that the relapsing fever spirochete found in these countries is identical with the one found in Panama.

We propose the name *Spirochaeta neotropicalis* for the organism which we have referred to as the spirochete of Panama, because it is found in the Neotropical region and because we believe it to be a distinct species. The term spirochete, to paraphrase the words of Fantham, Stephens and Theobald, is used in this connection without prejudice as to the organism's ultimate correct generic name.

LEWIS B. BATES, M.D.
J. HAROLD ST. JOHN, M.D.
Ancon, Canal Zone

EXCISION OF BENIGN PIGMENTED MOLES

To the Editor.—Benign pigmented moles as a rule can be removed with the knife. The pigmented area should be given a margin of at least one half inch or more, and the wound can be closed. One should divide the skin and remove some of the fat. If the margin of the pigmented area is indefinite, a wider margin should be given. Even if one cannot close the wound, one should never give a narrow margin. The only danger of excising a benign mole is to leave a piece of the tumor behind.

If the mole is situated in a position where it is difficult to give a good margin, for example near the ala of the nose or the eyelid, the cautery should be used. The cautery must be hot enough to cut through the skin readily. When I think that the mole has become malignant, I always use the electric cautery *instead of the knife, give a very wide margin of skin* and remove the subcutaneous fat and fascia.

We have on record at least 300 benign moles without a recurrence or death from metastasis. They were all completely excised with the knife or the cautery. During the same period of thirty years we have operated on at least 200 malignant moles with only one five-year cure.

In removing a mole, therefore, the skin and fat should be cut through, and should be given a good margin of healthy skin. As a rule the excision can be done with the knife under procain and the skin closed by any of the usual procedures. All elevated pigmented moles should be removed.

JOSEPH C. BLOODGOOD, M.D., Baltimore

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

PENETRATION OF ROENTGEN RAYS

To the Editor.—Your answer to my inquiry about the penetration of the roentgen rays (THE JOURNAL, June 24, p. 1982) is still not clear to me. 1. I am surprised that you state that the square of the distance has no reference to penetration. *If not, what is the law for penetration?* 2. The alpha, beta and gamma rays had use as names for the rays of the roentgen rays perhaps before we had radium, if I remember correctly; so why are they applied only to radium? Why not compare the gamma ray from the roentgen ray to the so-called gamma ray of radium? 3. Further, I am still more confused when you tell me that intensity refers to amount and penetration to quality.

PALL PEVISTON, M.D., Newnan, Ga.

ANSWER.—1. The law of penetration is that any beam or any part of a beam of the roentgen ray is absorbed in any given substance, in proportion to the cube of its wave length. It is, of course, absorbed at different rates in different substances, the rate of absorption being as the cube of the atomic number of the absorber. There is a regular formula for this absorption rate which is given in an article by Dr. A. W. Hull (*Journal of Radiology* **1**: 27 [Jan.] 1920). The distance has nothing to do with the rate of absorption, or penetration, of the roentgen ray.

2. The terms alpha, beta and gamma are not usually applied to rays issuing from a roentgen-ray tube. These three names are used to indicate radiations from radium which is composed of three distinct kinds of rays. The alpha ray is the emission of a gas, the beta ray is a stream of electrons such as passes from the cathode to an anode of a roentgen-ray tube, gamma rays are electromagnetic waves. Only the electromagnetic waves come out of a roentgen ray tube. The gamma ray from radium is exactly the same thing except that the shortest wave coming from the ordinary roentgen-ray tube is in the neighborhood of one tenth of an Engstrom unit in length, while most of the gamma radiation from radium is of much shorter wave length than this. It has been estimated that in order to get from a roentgen ray tube wave lengths as short as the shortest wave length from radium it would be necessary to operate a tube at 1,000,000 volts.

3. With the roentgen ray just as with a beam of white light the beam includes many different qualities of radiation. A beam of white light may be divided into seven primary colors with all kinds of intermediate shades. This is because different wave lengths produce different color sensations in our organs of vision. A beam of roentgen ray will be composed of many different wave lengths or qualities of radiation. While these waves produce no sensation of color and do not affect our vision the different wave lengths, or qualities are just as distinct in their properties as are different wave lengths in a beam of white light. Two things must always be taken into consideration as applied to a beam of roentgen ray, intensity and quality, intensity refers to the amount of radiation, and quality means the same thing as penetration.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALASKA: Juneau, Sept. 5. Sec., Dr. Harry C. DeVighne, Juneau.

MASSACHUSETTS: Boston, Sept. 12-14. Sec., Dr. Samuel H. Calderwood, State House, Boston.

NEW HAMPSHIRE: Concord, Sept. 7-8. Sec., Dr. Charles Duncan, Concord.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 25-28. First Professional Examinations. Mr. Herbert J. Hamilton, State Education, Albany.

Iowa March Examination

Dr. Rodney P. Fagen, secretary, Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, March 21-23, 1922, and also reports that one candidate was licensed by reciprocity and one by endorsement of credentials at the meeting held April 12, 1922. The examination covered 8 subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. The following colleges were represented:

PASSED		
College	Year Grad.	Per Cent.
Harvard University	(1918)	87.6
University of Berlin	(1920)*	85.6

LICENSED BY RECIPROCITY		
College	Year Grad.	Reciprocity with
Ohio State University College of Medicine	(1919)	Ohio

ENDORSEMENT OF CREDENTIALS		
College	Year Grad.	Endorsement with
Northwestern University	(1915)	N. B. M. Ex.

* Graduation not verified.

Maine March Examination

Dr. Adam P. Leighton, acting secretary, Maine State Board of Registration in Medicine, reports the written examination held at Portland, March 14-15, 1922. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seven candidates were examined, all of whom passed. The following colleges were represented:

PASSED					
College	Year Grad.		Year Grad.		Per Cent.
Harvard University			(1913)		84
Tufts College Medical School	(1920)	82	(1921)	85	87 88
Dartmouth Medical School			(1875)		77
McGill University			(1918)		86

Book Notices

RINGWORM AND ITS SUCCESSFUL TREATMENT By John P Turner, M D Medical Inspector of Public Schools Philadelphia Cloth Price $1 net Pp 62 with 8 illustrations Philadelphia F A Davis Co, 1921

This monograph is written, according to the foreword, because of the author's success in treating ringworm of the scalp by his method The major portion of the book consists of a discussion of the clinical and pathologic features of the disease This part is sketchily and poorly written, and contains less information about the subject than any standard textbook on dermatology The description of Turner's method of treatment of ringworm of the scalp and body occupies a scant three pages of the book In treating infection of the scalp, tincture of iodin oil of cade, 20 per cent ammoniated mercury ointment and 20 per cent resorcin ointment are used sequentially for several days each The author states that from one to fifteen such courses of treatment may be necessary, but that few cases fail to yield to four such courses In treating ringworm of the body he recommends the use of tincture of iodin for three days, to be followed by ammoniated mercury ointment The latter treatment cannot be condemned too strongly, as it is well known that these two drugs, if used together, frequently provoke a severe dermatitis The book can scarcely be recommended as furnishing anything more than an outline of a method of treating ringworm of the scalp by the intensive use of the commonly employed agents

THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN By Zachary Cope R A M D M S Surgeon to Out Patients St Mary's Hospital Paddington Cloth Price $4 Pp 223 with 28 illustrations New York Oxford University Press 1921

In the first place, exception must be taken to the use of such a monstrosity as the term 'acute abdomen' Such medical slang is unjustifiable in either spoken or written scientific language The proper title for this book should be 'The Early Diagnosis of Acute Abdominal Diseases" While most of the facts in this monograph are well known by surgeons of experience, yet as is stated in the preface 'there are still many who do not appreciate to the full the significance of the earlier and less flagrant symptoms of acute abdominal diseases" For these, for whom the work is written, there is an abundance of practical clinical observations presented in an interesting, scientific, and delightfully clear and concise manner One can hardly agree with the statement on page 5 that "it is acknowledged by those who are acquainted with modern surgical results that the best and only justifiable treatment for cholecystitis is by surgical intervention" Chapter III, on examination of the patient is quite incomplete, and one is struck by the lack of any evident order in performing the examination Many valuable points are brought out however In the description of ruptured gastric ulcer no mention is made of leukocytosis (either in the direct diagnosis or in the differential diagnosis, which is often of great value), blood in the vomitus or roentgenologic examination Fluoroscopic examination not infrequently reveals the escaped air especially if the patient is examined in the upright position when the air is seen as a bright zone between the upper surface of the dark liver shadow and the diaphragm Too much emphasis is placed on obliteration of the liver dulness, caused by the escaped air This finding is rare, and this portion of the chapter gives an entirely erroneous evaluation of this sign The subjects with which the author has apparently had considerable experience are well discussed in the chapter on the early diagnosis of abdominal injuries, but some of the most common conditions are not taken up at all, so that one face to face with his first severe acute traumatic abdominal emergency would not get much real help from this chapter Rupture of the liver is not discussed at all, although it is more frequent than rupture of all the other organs taken together Edler found rupture of the liver in 183 instances, whereas rupture of other parenchymatous abdominal organs was noted in only 176 Rupture of the spleen is similarly not discussed This, likewise, is surprising, when one remembers that, next to the liver, the spleen is the organ most frequently ruptured Geil, in a tabulation of 494 cases in which internal organs were ruptured, found rupture of the liver in 59 9 per cent , of the spleen in 33 per cent , of the kidney in 21 5 per cent , of the intestine in 11 1 per cent , of the stomach in 7 1 per cent , and of the bladder in 4 4 per cent Thus it is evident that the solid organs are much more frequently ruptured than the hollow ones Cope, however, devotes practically all his attention to the latter, and even goes so far as to state that "the solid viscera of the abdomen (liver, spleen, pancreas, kidneys) are situated high up in the abdomen largely under cover of the ribs, the hollow tubes (intestines, bladder, ureter and stomach) are more exposed to injury" In general, however the work is worthy of an accessible place in the library of all internists, general practitioners and beginners in surgery

DIE WASSERSTOFFIONEN KONZENTRATION Ihre Bedeutung für die Biologie und die Methoden Ihrer Messung Teil I Die Theoretischen Grundlagen Von Dr Leonor Michaelis A O Professor an der Universität Berlin Second edition Paper Price, $1 70 Pp 262 with 32 illustrations Berlin Julius Springer 1922

The first edition of this valuable work was published in 1914, and since that time, in spite of the war, the topic it covers has been enormously developed The clinical chemist has come to recognize the importance of quantitative estimations of hydrogen ion concentration, and is no longer satisfied with the mere qualitative statement that a fluid is alkaline or acid Professor Michaelis is recognized as one of the pioneers in this field, and his first edition was an important contribution to its development The second edition is completely rewritten and not merely a reedited book It will continue to be indispensable to all laboratory workers in biologic and medical chemistry This volume merely concerns the theoretical basis of the subject, leaving to a second part the consideration of methods thus permitting a wider consideration of the underlying principles than was given in the first edition

TRAITÉ DE PATHOLOGIE MEDICALE ET THÉRAPEUTIQUE APPLIQUÉE Publié sous la Direction de Emile Sergent Membre de l'Academie de Medecine Medecin de la Charité L Ribadeau Dumas Medecin des hopitaux et L Babonneix Medecin des hopitaux Tome IV Appareil Circulatoire Par Pr Vaquez Lian Heitz Leconte Paper Price 45 francs Pp 1071 with 161 illustrations Paris A Maloine et Fils 1922

This volume represents the current views of the French school concerning diseases of the circulatory apparatus It has been carefully written It is distinctly not a simple compilation, for each of the four authors has put into his writing his own personality and his own views, based largely on clinical observation and investigation Vaquez writes the introductory chapter, Lian treats of diseases of the heart Heitz discusses the diseases of the aorta and arteries, and Leconte discusses diseases of the veins and lymphatic vessels Clarity of style good print and good paper with well chosen and well executed illustrations make the reading of the book a pleasure If a second edition of the book is ever published, it is to be hoped that it will be in two volumes As one, it is too heavy and bulky

HYPERPIESIA AND HYPERPIESIS (HYPERTENSION) A Clinical Pathological and Experimental Study By H Batty Shaw M D F P C I Physician to University College Hospital Cloth Price $6 50 Pp 191 with illustrations New York Oxford University Pres 19_2

Hyperpiesis or hypertension is a sign of the disease hyperpiesia, the pathologic state characterized by cardiac hypertrophy and altered blood vessels The author bases his study on the clinical histories and necropsy findings in fifty cases The clinical features and the origin of the hyperpiesis and of the cardiac hypertrophy are discussed Shaw believes that a toxic substance is responsible The relation of this condition and this unidentified pressor substance to uremia eclampsia, renal changes, infections, convulsions, coma, retinal changes, etc, is taken up As a part of a concluding chapter the therapy of hyperpiesia is briefly considered The book represents thoughtful study, and extended and careful clinical observation and pathologic examination Though

much of it must still be classed as theoretical or speculative, the work is a real contribution to a still imperfectly understood subject

THE PHYSIOLOGY OF GOUT RHEUMATISM AND ARTHRITIS AS A GUIDE TO ACCURATE DIAGNOSIS AND EFFICIENT TREATMENT By Percy Wilde M D Physician to the Lansdown Hospital Bath Cloth Price $3 50 Pp 229 with 31 illustrations New York William Wood & Co 1922

This is an interesting and instructive book, presenting the subjects of gout, rheumatism and arthritis from a point of view not commonly accepted The author is not in sympathy with the theories of excess nitrogenous food or of bacterial invasion as etiologic bases of these conditions, the uric acid theory he considers founded on mistakes He contends that all these conditions are produced by aberrations of physiologic processes rather than by disease and that these aberrations have to do with the production and elimination of lactic acid His contentions are logically propounded, and seem well supported by experiment His therapy is based on the physiology of the skin and its important role in elimination

GLANDS IN HEALTH AND DISEASE By Benjamin Harrow Ph D Associate in Physiological Chemistry College of Physicians and Surgeons Columbia University Cloth Price $2 50 Pp 218 New York E P Dutton & Co 1922

This book is written for the lay, rather than for the medical, reader It is a companion volume to the excellent book on vitamins prepared by the same author It is a safe reserved, clean-cut statement of the scientific knowledge concerning the glands and their functions It is written in a simple, readable style without any of the fantastic hyperbole that has characterized some of the other recent books on this subject It should be serviceable to those physicians who wish a simple introduction to the subject, as well as to the interested layman

WORLD METRIC STANDARDIZATION AN URGENT ISSUE A Volume of Testimony Urging Worldwide Adoption of the Metric Units of Weights and Measures—Meter—Liter—Gram Compiled by Aubrey Drury in collaboration with Clifton Hildebrand, W Mortimer Crocker Harry Allcock M I E E and other Members of the World Metric Standardization Council Cloth Price $5 Pp 524, with illustrations San Francisco World Metric Standardization Council 1922

This volume contains a summary of the testimony gathered by the World Metric Standardization Council during recent years for the purpose of supplying legislators, editors and the public with the facts available, so that they may aid the movement Among the sixteen chapters, those on metric units in the world today, and world metric clues, are valuable as references The book contains an adequate index

A POCKET SURGERY By Duncan C L Fitzwilliams C M G M D Ch M Surgeon in Charge of Out Patients and Lecturer in Clinical and Operative Surgery St Mary s Hospital London Cloth Price $3 75 net Pp 348 New York Longmans Green & Co 1921

Surgery is the most difficult of the clinical branches to teach from a textbook The usual single volume for students is too brief, the "system" is too comprehensive and confusing In using this little volume, one should bear in mind the limitations imposed by the author in the preface It "attempts to give all of the necessary headings and only a short account of the mere details which the student should have learned elsewhere" It is of use for a hasty review, not for detailed study

DOCTORS—E TRE NOUS Short Stories By James Bayard Clark Cloth Price $1 Pp 66 with illustrations New York The Medical Times Company 1922

In this book are collected three stories which originally appeared in "The Medical Pickwick" 'An Unlooked for Conclusion' is a satire on the meeting of the average medical society "How Dr Jones Came Back" is a semihumorous sketch of rather moderate interest 'The Narrow-Minded Layman, the third sketch is a direct attack on the Potter method of version in obstetrics, and on similar radical procedures All will be read with interest by physicians, since the stories deal with problems directly concerned in medical life

Miscellany

THE WEIL-FELIX TEST

The Weil-Felix test for typhus fever has been in use at the New York quarantine station for more than two years during which time 1,698 tests have been made Twenty of these tests were made, say Holt-Harris and Grubbs in *Public Health Reports*, July 14, on clinically positive typhus patients, forty-three in atypical or clinically doubtful cases, and 737 in cases of various acute diseases In all but two of the clinically or atypically positive cases of typhus fever, the first Weil-Felix tests were positive The two negative tests were made early in the disease, and later both became positive It is stated that all cases giving a positive reaction were undoubtedly typhus fever

The Weil-Felix reaction depends on the agglutinating property of typhus serum on certain strains of the *B proteus* group which were isolated by Weil and Felix in 1915 from stool and urine of typhus fever patients The discoverers designated these strains X 2 and X 19 The New York station has used the strain X 19 exclusively A tentative test on a glass slide is made on shipboard, for which a single drop of blood is sufficient The drop of blood is allowed to clot and then mixed with four drops of saline solution placed near it, a drop of this mixture is carried over to three other drops of saline on the slide near by and mixed a drop of the second mixture is then carried over to a single drop of saline placed a little farther along on the slide thus making serum dilutions of 1 5, 1 20, and 1 40 approximately A small amount of a twenty-four hour agar slant culture of X 19 is now placed at the margin of each dilution and emulsified The slide is then rotated on its long axis against a dark background A positive reaction—agglutination—is shown by the appearance of white flocculi which are readily discernible Prompt and complete clumping especially in dilution 1 40, points to typhus fever When the tentative test is positive, the patient is bled from the basilic vein and a confirmative test is made in the laboratory With this method agglutination in dilution 1 40 is regarded as diagnostic of typhus fever It is claimed that the Weil-Felix test not only increases the protection to the country against typhus but is economically important in shortening the delay to commerce, and the traveling public.

BLINDNESS IN THE UNITED STATES

Statistics compiled by the Bureau of the Census on the causes of blindness in the United States show that there are 52 567 blind persons in the country, in 35,788 of whom definite information as to the cause of blindness was obtained In 13,818, or 38 6 per cent of the 35 788 for whom the cause was reported, the blindness was caused by some specific disease of the eye, such as cataract or glaucoma, and in 5 623 cases, or 15 7 per cent, it was a result of some general disease such as measles meningitis or scarlet fever Accidents were responsible for 5 913 cases or 16 5 per cent of the total Of this number 1,429 persons lost their sight through explosives or firearms Cataract, the leading cause was reported by 4 896, or 13 7 per cent Glaucoma ranking next, was reported by 1,932, or 5 4 per cent Atrophy of the optic nerve was given as the cause by 1,756 or 4 9 per cent Ophthalmia neonatorum or 'babies' sore eyes was reported by 1,198, or 3 3 per cent of the total number reported Recent statistics of admissions to schools for the blind show that there has been a marked decrease in the amount of blindness due to this cause These figures show that only 14 7 per cent of the new students admitted in 1917-1918 were reported blind from ophthalmia, as against 24 2 per cent of the students then attending who had entered the previous year This decrease reflects the more general adoption of scientific methods of treatment and especially the routine use of silver nitrate drops in the eyes of infants The campaign to eliminate trachoma also appears to be successful, as trachoma and

sore eyes" together were reported by only 3 per cent of the total for 1920, as against 5 2 per cent for 1910 The causes of blindness, as summarized in the 1920 census are given in the accompanying table

CAUSES OF BLINDNESS,	1920 Number	Per Cent Distribution
Causes

MEDICINE IN POLAND

Polish medicine, says Dr W Szumowski, professor in the Cracow Medical School, began in the thirteenth century with Vetellus, a Silesian, who wrote Perspectiva," a work on the anatomy of the eye In the thirteenth and fourteenth centuries, Polish students studied in Paris and Bologna The University of Cracow was founded in 1364, one of its component schools being a medical faculty with two professors Owing to the death of Cassimir the Great, its founder, the school was suspended until 1400, when the university was reinaugurated by Ladislaw Jagello, who gave the university its name Jagellonian The study of medicine was, however, neglected, and sometimes there was not even a professor Physicians in that period usually combined astrology, mathematics and medicine as happened with Martin Krol and Peter Gaszowiec, both professors of medicine in the university, and Nicolas Kopernik, the astronomer and physician, who was a pupil in the same school In the sixteenth century, the Cracow Medical School assumed greater importance, and its most famous character was Mathias de Miechow, also called Miechowita professor of medicine rector of the university and author of several medical, geographic and ethnographic books The only diplomas granted were bachelor and master, the first degrees of doctor being granted in 1527 to three Poles Among famous Renaissance physicians may be mentioned Joseph Strus (Struthius, 1510-1568), who graduated in 1535 at Padua, where he was appointed professor of theoretical medicine At Padua he published his important work on the pulse ("Ars sphygmica"), which was received so warmly that 800 copies were sold in one day His reputation was so great that he was called to attend the two greatest princes of his time, Solyman II and Phillip II Another prominent physician was Sebastian Petrycy (1554-1626), whose sculpture still adorns the scepter of the school A period of decay followed until the reorganization of the school in the latter part of the eighteenth century, when the two chairs were filled by Andrew Badurski and Raphael Czerwiakowski Among modern representatives of the Cracow Medical School may be mentioned Louis Bierkowski (1801-1860), known through his anatomic and surgical charts, Joseph Dietl (1804-1899), a famous clinician and one of those who did most to stop the practice of routine venesection Joseph Majer (1804-1878), a physiologist, first president of the Academy of Sciences of Cracow, Louis Teichmann (1823 1895), professor of anatomy, known through the crystals named after him, and the surgeons Jean Mikulics (1850-1905) and Louis Rydygier (1850-1920)

Another Polish medical school was at Vilna Its most remarkable product was Andrew Sniadecki (1768-1838), a physician biologist and chemist, who began to study medicine at Cracow, and finally graduated in Pavia, Italy On his return to Vilna, he became a professor and one of the most popular physicians in the province His most important work was "Teorja jestestw organicznych" (Theory of Organized Beings) published in 1804, and translated into both German and French His ideas apparently influenced the German biologists John Muller and Wrzosek, and the chemist Liebig The Vilna Medical School remained open until 1840, when it was finally closed by the Russian government

The medical school at Warsaw was founded in 1809 even before the university, which was founded in 1816 It was closed during the 1830 revolution, and remained quiescent nearly thirty years The lack of physicians became acute, and Alexander II permitted the opening of a medicosurgical academy at Warsaw in 1857 In 1862, the academy became a part of the Warsaw Superior School Among its most prominent professors were Titus Chalubinski and Ignace Baranowski In 1869 the Superior School was named Imperial University, and its Russian tendencies were intensified until after the war it passed finally under Polish control

Medical courses were also organized by the Austrian government at Lvow in 1773, the first professor there being Andrew Krupinski A university was established in 1784, but it was soon closed, and the Lvow School was authorized to give only the diploma of 'surgeon" The present medical school was opened in 1894

Medicolegal

Another Court Favors Charitable Hospitals

(Emery v Jewish Hospital Association (Ky) 236 S W R 577)

The Court of Appeals of Kentucky, in affirming a judgment overruling demurrers to the defendant's answer and dismissing the petition in this action by the plaintiff to recover damages for injuries which he alleged that he had sustained through the negligence of the defendant, its servants, agents and employees, while he was employed in operating an elevator on its premises, says that there was no precedent in that jurisdiction on which the rights of the parties having such relations to each other as those in this case could be appealed to for guidance But the conclusion reached is that a charitable corporation, organized and operating under Sections 879-882 of the Kentucky Statutes, for the purpose of conducting a hospital, to which all funds are donated or devised by individuals for the purpose of operating a hospital for the treatment of the poor and needy sick, and are expended for that purpose, no profit or gain accruing to any person from the operation of said institution, is not liable in damages for the negligent acts of its managers, servants or employees, to any persons whatsoever The manager, servant or employee will be liable in damages to any person whom his negligent act in the course of his employment may injure, but the corporation is not liable This principle is adopted for the reason that the funds of such an institution are donated to it or devised to it in trust that they will be expended for the charitable purpose of ministering to the poor and needy sick, and no other, and such a corporation is a trustee of funds for such purposes, and neither it nor its trustees or officers receive any profit from its operation, and while it is not held that, according to the ordinary principles governing the administration of a trust, these funds might not be diverted to the payment of damages incurred in its administration, they should not be

diverted to any such purpose. The diversion of such funds in such a way would probably destroy the institution, and a wise public policy forbids such a result It is to the interest of the public that such institutions be maintained, and a principle which requires that the interest of an individual be subordinated to the good of the public is not a stranger to our legal principles It probably might be said that it is a hard rule which exempts such an institution from liability to a stranger, or to an employee, but it only works the same hardship on a stranger or employee as the principle which exempts a governmentally conducted charity from any liability to them, and the defendant is doing the same service as such an institution governmentally conducted might do

Rules for Determining Percentage of Loss of Vision

(Turpin St Regis Paper Co et al (N Y) 192 N Y Supp 85)

The Supreme Court of New York, Appellate Division Third Department in affirming an award under the workmen's compensation law says that the award was questioned only on the ground that the evidence did not show a loss of 16 per cent of vision, for which the award was made A similar question arose in *Johnson* v *United States Railroad Administration,* 185 N Y Supp 338, in which the question was, what loss of use of an arm had been suffered, and the court said 'There is, of course no method by which the percentage loss of the use of an arm can accurately be determined It is at best a matter of rough estimate and approximation The question is one of fact for the industrial commission to be determined by it on such proof as physicians may give, in accordance however, with its own experience, good sense and judgment" This court thinks this was the correct rule to be applied in this case The court does not think that it should determine whether the Snellen test or some other test furnishes a proper rule for guidance of the board in determining percentage of loss of vision Necessarily some test must be used, but this is only an element of the evidence, and the board must pass upon the evidence determining what evidence it shall accept and what weight shall be given to its various parts By the Snellen test, the claimant's eyes, with the aid of glasses, showed 84 per cent of normal vision, or a loss of 16 per cent Evidence was presented tending to show that this was the measure of the 'direct or central' vision only, while there are other elements of vision that must be taken into account to determine the "useful vision," namely, "field vision" and the "binocular vision' Under this standard of measurement, the claimant's useful vision was found to be 93 5 per cent, showing a loss of 6 5 per cent Although one physician testified that another formula was more accurate than the Snellen test, the board was not bound by the evidence of the expert It was for the board to determine, the nature of the test having been fully explained, which test it should use in determining what partial loss of the use of the eye the claimant had suffered The board was still at liberty to make use of its experience good sense, and judgment in determining what the actual loss was The board may have been of the opinion that the direct vision was the vision most essential to the employee engaged in hazardous employments, and that he was handicapped in his work to the extent that his direct vision was damaged even though his field vision and binocular vision were normal

Cannot Require Examination in Slander Case

(Mann v Bulgin (Idaho) 203 Pac R 463)

The Supreme Court of Idaho says that the plaintiff in this action for slander alleged that on a certain date the defendant in a public address maliciously referred to him as a syphilitic renegade, that the defendant stated that the plaintiff was syphilitic, that he could prove it, that he had in his possession a certificate by a physician to that effect The defendant denied all the allegations of the complaint Thereafter the district judge made an order appointing three physicians to make a physical examination and test of the plaintiff for the purpose of ascertaining whether or not he "has or had or is afflicted with the disease commonly known as syphilis or was or is a syphilitic person' The plaintiff refused to submit his person to the board of physicians so appointed for examination The case being called for trial, the plaintiff again refused to comply with the terms of the order, and thereupon the court entered judgment dismissing the action

In reversing that judgment, the supreme court goes on to say that the language charged in the complaint was actionable per se or in and of itself The only reasonable construction of the language of the complaint was that it alleged that the defendant charged the plaintiff with being syphilitic at the time the words were uttered, otherwise the language charged would not be actionable per se When a complaint charges the use of language which is actionable per se, the falsity of the defamatory word is presumed, and it is not necessary that the plaintiff shall in the first instance offer any proof that the words were false A defense of truth must be specially pleaded, and a plea of justification must be as broad as the charge As the pleadings stood on the trial of this case the defendant was entitled to show the truth of the charge made by proving that at the time the words were uttered, the plaintiff was infected with syphilis Was the defendant entitled to the order of the court requiring the plaintiff to submit his person to examination?

On the question as to whether or not in an action for damages for personal injuries, the court may require the plaintiff in the case to submit to physical examination by a board of physicians appointed by the court and in case of refusal dismiss the action, the authorities in the United States are in hopeless conflict, and are not reviewed here nor is any opinion expressed on that question, as it is considered that the situation in this case was entirely different Here the plaintiff was not suing to recover damages for personal injuries but to recover damages for injury to his good name and reputation caused by the language alleged to have been uttered by the defendant The damage of which the plaintiff complained did not result from the falsity of the alleged charges The damage to him was just as great whether the charges were true or false hence he was relieved of the burden of proving the falsity of the charges But the law would not suffer him to recover damages for injury to a reputation which he did not justly deserve to have Consequently, the defendant could relieve himself from liability for the damage done by proving that the words uttered were true but he must take the entire burden of proving justification on himself This court knows of no rule of the common law or statutory provision of the state of Idaho which authorizes the court to enter an order requiring a plaintiff who has been damaged in his good name and reputation to submit to physical examination, in order to supply a defendant with the means of proving that the statements made by him were true

Neuropathic Manifestations in Infants and Children as Result of Anaphylactic Reaction to Foods Contained in Their Dietary W R Shannon, St Paul —p 89

Bilateral Hypoplastic Cystic Kidneys—A case simulating chronic diffuse nephritis, occurring in a girl, 3 years of age is reported by Greene Clinically, the findings were those of a long standing renal insufficiency and were identical with those seen in cases of typical chronic interstitial nephritis The family history was negative The condition was present from birth, but symptoms of renal disturbance first appeared at the age of 8 months At this time the child had convulsions that probably marked the first of a series of uremic attacks Following the convulsions, the patient was put on a faulty diet and evidences of rachitis followed Blood smears showed a pronounced secondary anemia The remarkable clinical improvement following a single transfusion is of interest This is especially so since there apparently was no great stimulation of the hematopoietic system The increase in the erythrocyte count lasted for about a month, which corresponds well with the average life of the transfused blood corpuscle During this period there was a great improvement in the general condition of the patient and even a slight increase in the phenolsulphonephthalein output, indicating that the kidneys were functionally benefited by the general improvement The specific gravity of the urine was low, the limits of variation being from 1 005 to 1 012 Albumin was present in the urine throughout the whole period of the disease The amount was increased during the uremic attacks, but was never large No Bence-Jones or protein body other than serum protein was demonstrable in the urine Casts were absent even during the terminal stages of the disease Death was due to uremia, though starvation acidosis undoubtedly was a contributing factor The pathologic picture was that of bilateral hypoplasia of the kidneys with cyst formation The renal tubules were characterized by marked cystlike dilatations, especially in the proximal convoluted tubules There was no evidence of obstruction and the dilatation apparently was secondary to functional hypertrophy of the tubules

Ultraviolet Radiation in Rickets—Five children showing clinical evidences of rickets confirmed by roentgenographic examination of the bones, were treated by Kramer et al by systematic exposure to the rays from the mercury vapor quartz lamp This was followed in every instance by healing of the rachitic process in the bones The inorganic phosphorus concentration of the serum of these children was low (from 2 7 to 3 2 mg) before the treatment was begun and gradually increased to a maximum of 6 mg with the appearance of calcium deposition in the bones So far as could be judged, healing of the bones following radiation occurred at about the same time as it does after the administration of cod liver oil The changes in the phosphorus concentration of the serum were identical with those observed after cod liver oil treatment The pigmented skin of the negro child did not interfere with the action of the light rays The colored children required no more intensive treatment to bring about healing than did the white children

Thymus Apoplexy—The two cases reported by Wahl and Walthall are similar in many respects Symptoms of meningeal irritation, lateral nystagmus and generalized icterus were present in both infants Labor, while not normal, was not unduly difficult or prolonged in either case In both cases there was a marked increase in the coagulation time of the blood In each case the necropsy showed a cerebral hemorrhage, inflammatory changes in the lungs suggestive of syphilis and a diffuse hemorrhagic infiltration of the thymus in which the extravasation of blood was both intralobular and interlobular and was associated with suppuration, necrosis and marked proliferation of the reticular epithelial cells The cases differ in that the second patient was aged 6 weeks and the first 4 days In the first case, the hemorrhages were more generalized and extensive, labor was more difficult, the immediate cause of death was cerebral hemorrhage In the second case, bronchopneumonia was probably the more immediate factor causing death In both cases the Hassall's corpuscles were numerous but in the first case they were dilated and often contained a purulent exudate forming early DuBois abscesses On the other hand, the second case showed a striking perivascular inflammatory reaction with swelling of the vascular endothelium and also marked thrombophlebitis of the smaller veins One of the large veins in the first case was partly occluded by a thrombus The condition seems to be associated with syphilis more than any other factor, but circulatory stasis, trauma nonspecific infections and a hemorrhagic tendency are contributing, if not the main factors in some cases There is no way of making a clinical diagnosis

Carbohydrate Requirement of Children—The carbohydrate intake of more than 100 healthy children, from 1 to 18 years of age, studied by Holt and Fales, averaged 10 gm per kilogram A diet excessive in carbohydrate leads to an abnormal deposition of fat without a corresponding increase in muscle development Children taking such a diet have feeble resistance to infection There is evidence that a relationship exists between the high proportion of carbohydrate in the modern diet and the prevalence of dental caries Definite digestive disturbances chiefly intestinal may be produced when the carbohydrate in the diet is excessive There may result increased fermentation with loose acid stools or constipation with flatulence and abdominal distention When long continued these disturbances are very difficult to control

Neuropathic Manifestations in Children a Food Anaphylaxis—Eight cases showing marked evidences of the presence of the so called neuropathic diathesis in infants and children are presented by Shannon In four of these cases definite evidence of the exudative diathesis was also present while in another case there was a positive history of such a condition in the past The remaining three cases gave no evidence suggestive of the presence of an exudative diathesis All the patients showed the presence of protein sensitization by cutaneous tests All showed definite relief from the nervous symptoms on the institution of specific therapy directed at the proteins to which they were sensitive In all but one of the eight cases the proteins concerned were those of foods contained in the dietaries of the patients In one case animal emanations of pollen proteins might have played a part In one case the nervous symptoms could be relieved or brought on by the exclusion from or the addition to the diet of the food to which the patient was sensitive Evidence is presented showing that anaphylaxis is a sound, theoretic basis for the explanation of many of the symptoms of the so called neuropathic diathesis

Roentgenologic Findings in Mongolism.—The only condition which may be considered as in any way characterizing the roentgenologic picture of mongolism according to Clift is the disproportionate developmental deficiency on the part of nose and maxilla. As regards the sella turcica, the findings are far from uniform. The sella differs in shape in about the same ratio as in normal persons. In fact, there is no single characteristic roentgenologic sign in this disease, and the only departure from normal is a generalized delay of bone development. This feature, except for a slight selective character on the part of the nose and maxilla, is common to a number of other diseases, some of endocrine origin and others due to obscure causes.

Foreign Bodies in Appendix.—Murphy reports two cases of appendicitis in which a pin was found in the appendix. One patient, a child, aged 17 months, nine months previously swallowed a pin. The roentgen ray showed the pin in the region of the ileocecal valve.

Erythema Multiforme of Mouth.—Two cases of severe stomatitis are cited by Butler. The mouth, tongue, and labial membranes were involved equally in both patients. The skin was normal in every respect. Two days following the examination one patient had beginning erythematosus patches on the dorsal aspect of the hands and feet that quickly developed into typical bullous lesions, and these made a correct diagnosis an easy matter. The other patient clarified the situation by saying that he, too, had suffered similar outbreaks on his hands and feet together with associated mouth lesions during the two preceding years, both attacks occurring in the spring, and attributed by him to plowing in the fields during rainy weather. Careful observation of this patient throughout the course of his illness failed to reveal any skin manifestations of the disease.

Morphea with Hemiatrophy of Face.—In the six cases reviewed by Osborne the evidence points strongly to involvement of the central nervous system. The history of trauma from four months to six years preceding the onset of symptoms in four of the cases, the necropsy findings of Steven and the neurologic findings suggesting an old inflammatory process in the brain of one of the patients, are all incriminating evidence. The close relationship between facial hemiatrophy and morphea is emphasized by the common etiologic factors involved and in the similarity of skin changes seen in the two conditions.

Blood Cholesterol in Syphilis.—The positive Wassermann reaction on the blood, McFarland asserts, apparently does not depend on high cholesterol value. Blood cholesterol values in syphilitic patients, in general, tend to be medium and low rather than high. The amount of arsphenamin given and the time between injections do not obviously affect the blood cholesterol values. There is, apparently, no relation between the cholesterol values and the clinical and serologic response of the patient. The only recognizable relation between the clinical type of syphilis and blood cholesterol values is the large proportion of high cholesterol estimations in syphilis of the central nervous system.

Intravenous Administration of Mercury in Syphilis.—Results obtained in the patients whom Conrad and McCann have treated lead them to believe that, in those cases in which the routine treatment has failed to reduce the Wassermann reaction or improve the clinical symptoms, mercury administered intravenously should be given a fair trial. Advantages claimed for this method over other modes of mercuric injections are that quicker results in treatment are obtained, a more accurate grading of dosage is made possible, the course of the disease can be more carefully observed, and a practically painless injection is assured the patient.

Salol in Smallpox.—The action of phenyl salicylate in smallpox was studied by Birchett and Lustberg. Salol, 10 grains four times a day, was the sole medicament used and careful observations were made of results. It was noted that the patients who began the medication in the preeruptive stage were left with only a few scars, and even those receiving the medicament during the eruptive stages showed less scarring than those who received no therapy. The severe confluent forms left a surprising aftermath. Some scarring, of course, remained as a remnant of the disease, but far less disfigurement than is usually seen in such cases.

Digitalis in Cardiac Disease. H. A. Christian, Boston.—p. 47
Quackery, Miracle Healing and Medical Cults. R. W. Lovett, Boston.—p. 53
Gummatous Cervical Adenitis. W. P. Coues, Boston.—p. 62

Digitalis in Heart Disease.—The dangers or toxic effects of digitalis, Christian states, are more serious as met with in medical books than in medical practice. Some one of these toxic effects or so-called digitalis dangers really should be sought rather than avoided in digitalis therapy. The real dangers in digitalis therapy are three: (*a*) Using a poor digitalis preparation; (*b*) Consciously or unconsciously prescribing too little of a potent digitalis preparation; (*c*) Not knowing when digitalis should be started and stopped. Digitalis usually is given in too small, i. e., insufficient dosage. Christian says he has yet to see the patient in whom too much digitalis had been given prior to seeing the patient. The large majority of cardiac patients seen by him have had too little digitalis, a small percentage have had enough digitalis, none have had too much, some have had too little from the point of view of dosage when actually they should have had none. Digitalis poisoning, of course, is possible, but it is one of the rarities of medicine. Digitalis is good for the symptoms and physical signs the patient has provided those symptoms and signs are the result of cardiac insufficiency, i. e., decompensation. The indications for starting digitalis therapy are the presence of symptoms and physical signs which are the result of cardiac inefficiency, i. e., decompensation. The symptoms and physical signs of cardiac insufficiency are breathlessness, cough, cyanosis, edema, pain, weakness, nausea, vomiting, enlargement of the liver, decreased urine output, rapid pulse. The indications for stopping digitalis are improvement in these symptoms and signs or the occurrence of some of the toxic effects of digitalis. The toxic effects of digitalis are nausea, vomiting,

certain arrhythmias, as bigeminal pulse and heart block, rarely diarrhea. It needs to be recognized that very often the digitalis which the patient purchases has but slight potency. A serious error is to regard a drop as a minim and to prescribe 15 drops of tincture of digitalis, thinking to give 15 minims, the patient taking 15 drops often gets but 5 minims, rarely more than 7 minims—both very small doses. This error accounts for much unconscious prescribing of too small a dose. The rest comes from the digitalis being of low potence. There should be definite evidences of cardiac insufficiency before digitalis is given. Increased heart rate alone is never the result of cardiac insufficiency and never the indication for digitalis therapy. Paroxysmal tachycardia does not respond to digitalis and digitalis does not affect simple tachycardia. No murmur of whatsoever sort, nor enlargement of the heart, in itself is an indication for digitalis therapy. Digitalis may be given in a single massive dose, or in a modified massive dose method, or in regularly repeated small doses. Any of these methods is effective. The chief difference lies in the length of time needed to produce a result. For the average cardiac case there is no real preference. In a few very severe cases the modified massive dose method is better. Occasionally the single massive dose may be life-saving. Digitalis therapy is very simple. Enough of a potent leaf prepared in any way, should be given by any accepted method of dosage, and the result is most satisfactory in almost every case. Standardizing on animals is helpful but by no means essential.

Two Cases of Early Carcinoma of Uterus Treated by Vaginal Panhysterectomy. L. F. Phaneuf, Boston.—p. 115

Cancer of Bladder—Smith asserts that all tumors of the bladder (barring some varieties, as fibromas) are potentially, if not actually, malignant, that early diagnosis by means of the cystoscope is the first requisite for successful treatment. Every misbehaving bladder should be considered guilty until it is proved innocent. The methods of treatment consist of fulguration, radiation by means of implantation of radium, excision of the tumor, total cystectomy, or, in hopeless cases, cauterization and permanent suprapubic drainage. The particular measure or combination of measures selected depends on the type of tumor which is disclosed by careful study of the case.

Panhysterectomy for Early Carcinoma of Uterus—One of Phaneuf's cases was a borderline case in which the disease was discovered only by examination of curettings from the uterus, the other case was an epidermoid carcinoma grafted on a procidentia of many years' standing. Both patients were subjected to vaginal panhysterectomies and made uneventful recoveries.

Modern Hospital on Pacific Coast. J. B. Cutter, Watsonville.—p. 239

Extramedullary Cord Tumor in Lower Dorsal Region—The outstanding features in the case cited by Schaller and Weeks were: onset with severe dorsal root pain, followed by motor loss in left lower extremity and evidence of both cord and root compression below the ninth dorsal cord segment, progressive paraplegia by involvement of right lower extremity, predominant flexor "shortening" paralysis, bilateral pathologic pyramidal tract signs and heightened tendon reflexes in lower extremities, positive Beevor sign, superficial sensation affected below the tenth dorsal root distribution for pain and temperature, deep sensation affected particularly for vibration sense, reflex movements of defense present, absence of sphincter involvement, colonic crises, compression syndrome in cerebrospinal fluid, at operation complete removal of an intradural glioma at the eleventh dorsal cord segment, convalescent period complicated by anemia, toxic polyneuritis, decubitus, ultimate complete recovery.

Bacteriology of Excised Tonsils—Of 218 pairs of tonsils removed, 7 per cent presented no microscopic evidence of disease. 96.1 per cent harbored hemolytic streptococci. Of the three groups of hemolytic streptococci, alpha, alpha prime and beta, the latter were found much more frequently. There seemed to be a relation between the pathology of the excised tonsil and the type of organism it harbored. Poured plates were found much more satisfactory than streaked plates. Roentgen-ray therapy was effective in reducing the size of the tonsils in but 16 per cent of this series. Hemolytic streptococci, the essential organisms in chronically infected tonsils, were permanently removed in but 50 per cent of the patients treated.

Tuberculosis in Children—A survey made by Ferguson of 1,184 white children disclosed that ten, or 0.84 per cent, showed clinical signs, symptoms and roentgen-ray evidence of active tuberculosis. These children were advised to take treatment in the sanatorium. Thirty, or 2.5 per cent, showed signs or symptoms more or less suspicious of activity. These children were referred to their family physician for observation.

Metabolism in Diseases of Thyroid—In a series of 105 persons, thirty-eight or 36.19 per cent, had normal metabolic rate; sixty-two or 59.09 per cent, had abnormally high metabolic rate, while five, or 4.76 per cent, had abnormally low rate. In analyzing the group of thirty-eight cases with normal metabolic rate, the final diagnoses come under the following heads in order of frequency: nontoxic goiters of different types, psychoneuroses, obesity and mental defectives, incipient tuberculosis, essential hypertension and so-called goiter wreckage cases. In the group of sixty-two cases with hyperthyroidism, Fahrni is convinced that many could not have been diagnosed definitely without the knowledge of existing basal metabolism. In the third group, that

of hypothyroidism, were found five very definite cases of myxedema There was no familial tendency in this group of five, and the origin was apparently spontaneous, with no history of degenerative or inflammatory disease of the thyroid gland nor of operation on the gland

Knife Blade in Brain—Davison's patient was stabbed in the left side of the head with a pocket knife, the blade penetrating the skull and was broken off Three days following the injury, the patient became dizzy, "turned sick and blind for the time being On the seventh day, the patient noticed a tingling in the foot, leg and hand on the right side which developed into a numbness and paralysis He lost control of his urine and stool the latter part of the second week He does not remember events during the third week and has only a hazy recollection of being brought to the hospital three weeks following his injury Roentgen-ray examination showed the knife blade 1⅛ inches in length, in the skull, in the left rolandic area When the section of the skull was lifted the dura was exposed showing the opening by the blade through which exuded a thick greenish-yellow pus The brain was not pulsating in this area A crucial incision made in the dura exposed an abscess the size of a small hen's egg Normal pulsation of the brain returned following evacuation of the abscess Six hours following operation tingling returned in the foot, leg and arm and the patient could move the foot slightly In twelve hours sensation was returning and he could move the arm and leg slightly Twenty-four hours after operation he could move the leg freely, sensation was improving rapidly and he could move the arm but not so well as the leg Sensation returned rapidly to the right side with some hyperesthesia in arm and leg The patient was dismissed from the hospital seventeen days following the operation with good use of himself, except slight incoordination of the muscles of the right hand and arm and slight right sided facial paralysis

Chronic Arthritis—Swaim emphasizes the fact that there are three distinct types of arthritis infectious atrophic and hypertrophic and that these types differ etiologically pathologically and clinically respond to treatment differently and should, therefore be differentiated Clinical data seem valueless unless these types are studied as separate pathologic entities

Operative Treatment of Scoliosis—Although operative procedures for scoliosis cannot be considered to have the test of time, Forbes believes they have been sufficiently encouraging to continue their employment The day may come when the field of usefulness of operative procedures may be extended but he hesitates to recommend their general use because the operation is a severe one It should not be carried out except after deep thought and consideration and then only by those who are accustomed to operate on the spine Perhaps at a later date its field of usefulness will be broadened but until it is possible to prove the enduring character of the ankylosis and the general benefit to the patient as shown by increased height and marked improvement in general condition it should not be employed except in desperate cases

Unusual Fractures—One of Peabody's cases presented the 'cartwheel fracture of the textbooks in which the leg is caught in a revolving wheel the resulting torsion completely disrupting the lower end of the femur from the shaft at the epiphyseal line The patient was not caught in a cartwheel, but was knocked down by a motor car, and in addition the break had the complication of being compound from the protrusion of the shaft through an external wound The second case was a fracture of the spine at a most uncommon point and producing a skiagraphic impression which is rather startling The neural arches of the first lumbar vertebra were fractured between the superior and inferior articular processes the fragments separating as the spine hinged in flexion on the disc in front so that the first glance at the roentgenogram gave the impression of complete loss of bony continuity in the spinal column The last patient, thrown from his horse was caught under the falling animal, with a consequent rupture and complete dislocation of the pubic synchondrosis, the two halves of the pelvis, rotating in opposite directions at the sacroiliac articulations, produced a fracture of both transverse processes of the fifth lumbar vertebra

Sarcoma of Femur—Gibbon reports the case of a boy, aged 16, who had a tumor of the lower end of the right femur which proved to be a large round cell sarcoma Within three weeks after curettage the patient came back complaining of a return of severe pain On examination it was evident that the tumor had recurred locally and was infiltrating the soft parts on the inner side of the knee, where there was a considerable swelling That this was then a rapidly growing sarcoma clinically seemed to be a just conclusion and amputation was advised The parents, however, refused this and again all of the tumor tissue possible was removed, and the area cauterized with phenol followed by alcohol Three weeks later the leg was amputated in the upper third of the thigh a local recurrence having again

occurred at about the end of three weeks Roentgenograms of the thorax at this time showed no metastases The boy is well six months after the amputation

Megacaryocyte in Peripheral Circulation—Minot points out that a megacaryocyte is seen commonly as an occasional cell in the peripheral blood of patients with myelogenous leukemia Less commonly they appear in relatively large numbers These giant cells also may occur in the blood under other conditions Their presence is indicative of a bone marrow under intense strain

Experimental Infectious Motor Paralysis—The attempt made by Wright and Craighead to infect young rabbits and guinea-pigs with material containing in all probability the virus of human infantile paralysis failed Incidentally, and presumably accidentally, a paralytic disease hitherto undescribed was observed in young rabbits associated with the presence of an organism showing certain definite characters This organism is found widely distributed in the organs of the affected animals and can be demonstrated in the urine The active destruction by the organism of the nerve cells of the spinal cord is particularly striking, and gives complete explanation for the paralysis observed clinically With the organism present in the urine the spread of the disease by contact can easily be understood The transfer of the infection from animal to animal by fleabites is possible but not probable The nature of the observed organisms is in doubt They represent probably an intermediate stage in the life history of some protozoan parasite.

*Biologic Reactions of Arsphenamin III Immediate Toxicity as Contrasted with Late III Effects, and Role of Agglutination in Production of Former J Oliver and S S Yamada, San Francisco —p 393
*Studies on Strychnin S Weiss and R A Hatcher New York —p 419

Immediate Toxicity and Late Ill Effects of Arsphenamin—Oliver and Yamada state that disodium arsphenamin may produce ill effects by means of either its physical or its chemical properties The physical toxicity produces an early reaction and is the result of intravascular agglutination of the red cells and multiple embolism The chemical toxicity requires some time for the production of anatomical lesions These consist of parenchymatous degenerations particularly in the kidney and liver

Studies on Strychnin—Studies were made by Weiss and Hatcher on a method for the extraction of small amounts of strychnin from tissues the absorption of strychnin by red corpuscles of the cat, the rate of disappearance of strychnin from the blood stream of the cat and the elimination of strychnin in the urine of man The liver appears to be the principal protective organ with reference to acute poisoning by strychnin, the kidney to be concerned mainly with the elimination of traces of the poison which reenter the circulation after having been fixed temporarily in those tissues which are incapable of destroying the poison

Homologue of Prostate in Female—The urethra of the female Johnson states corresponds only with that portion of the prostatic urethra of the male which lies between the internal urethral orifice and the orifice of the prostatic utricle The remainder of the male urethra is represented in the female by the vestibule The whole homologue of the prostate in the female is here demonstrated for the first time It consists of (*a*) The urethral glands which are the homologues of those prostatic glands in the male which lie above the orifice of the prostatic utricle (therefore true urethral glands) (*b*) Skene's ducts which are the homologues of the prostatic glands which lie below the orifice of the prostatic utricle (therefore sinus glands) Bartholin's and Cowper's glands are true homologues It is also demonstrated for the first time that the glands of Littre are represented in the female by a few poorly developed glands which have received the name "minor vestibular glands '

Mercurophen in Gonorrheal Urethritis—Mercurophen has yielded uniformly good results in Shivers' experience in the treatment of gonococcal urethritis and particularly in acute infections All cases with the exception of three showed a considerable decrease in the number of infected cells per field after the first and second treatments The solutions of mercurophen employed in this study were from 1 4000 to 1 10 000, these produced slight or no irritation of the urethra All treatments with mercurophen should be preceded by thoroughly cleansing the parts to be treated with a warm 1 8000 solution of potassium permanganate

Seminal Vesiculitis Causes Renal Retention—Mark and Hoffman report three cases of ureteral stenosis with hydronephrosis due to disease of the vesicles In one case it was possible to readily pass ureter catheters from below and yet there was complete retention above the juncture of the vesicle with the ureter

Unusual Case of Hypernephroma—The points of interest in Baumgarten's case were (1) the malignant neoplasm had been present and size unchanged for about twenty years without causing any disability or appreciable discomfort (2) It undoubtedly had its origin in an accessory suprarenal gland deriving its blood supply from an anomalous vessel, lying between the layers of the transverse mesocolon The patient made an uneventful operative recovery and showed no evidence of further trouble for some time, when she complained of pains in the upper left arm and over the eighth rib on the right side She refused a roentgen-ray examination of the bones Shortly afterward she developed similar trouble in the left femur and at this time a fusiform enlargement could be palpated in the humerus, and there was also an irritating cough with occasional blood streaked sputum A diagnosis of a generalized metastasis was made The patient died shortly afterward

Congenital Syphilis and Eruption of Teeth—That there is a definite inhibition of the eruption of the first teeth of some children who have a syphilitic taint seems to be an unquestionable fact In the cases cited by Moody that illustrate this condition there have usually been no other signs or symptoms of the disease These cases seem to indicate that congenital syphilis may be an even more important cause of failure of the first teeth to erupt than rickets and that the disease may cause no changes whatever in the shape, size, arrangement or interfere in any way with the enamel formation of these deciduous teeth even when the inhibition of eruption has been to a marked degree

Weaning the Infant J H Marcus Atlantic City N J—p 101

Chronic Pulmonary Abscess—A case of chronic pulmonary abscess lasting about a year, with a severe productive cough and with large quantities of odorless sputum, is reported by Greenberg as a unique case In reference to the symptomatology, the presence of an increasingly severe, productive cough, together with weakness usually associated with symptoms of fever, such as chills or chilly sensations, with languor and anorexia, with loss of weight and pain in the chest, may be said to be more often present than not The cough and the large quantities of malodorous sputum are the most constant of the symptoms In the author's case there was also dyspnea and marked weakness and loss of weight, with vague pains in the right side of the chest—but the sputum remained odorless The diagnosis is usually not difficult when the abscess ruptures early in the course of the disease as it usually does, giving rise to the characteristic sputum In cases where no such rupture occurs or when the sputum is not characteristic there may be considerable difficulty in arriving at a diagnosis The conditions with which chronic pulmonary abscess may be confused are chronic tuberculosis and capsulated empyema, bronchiectasis, neoplasm and broken down gumma of the lung and actinomycosis

Radium Treatment of Parotid Tumors—Of eleven operable cases treated with radium by Quick and Johnson, three of which were recurrent, ten are at the present time clinically

free of any neoplastic disease, but in five of these at the tumor site there is remaining a small quiescent fibrotic mass These patients have been well from 6 months to 3½ years The eleventh case in this group is still undergoing treatment, with a very satisfactory response Of forty three inoperable cases, twenty-three of which were recurrent, twelve are clinically free of active disease for periods ranging from 6 months to 3½ years Fifteen patients were definitely improved, locally and generally, and sixteen were so far advanced as to render quite negligible and palliative effect of the treatment Of the cases reported as clinically free of disease and which at the time of treatment were subjected to biopsy, five were of the mixed tumor type, four were reported as carcinoma, or adenocarcinoma, one as squamous epithelioma and one as Mikulicz disease The four cases of carcinoma that are clinically well represent a group that is considered very unfavorable from the standpoint of surgery Only one of these was considered at all operable The extent of disease of the other three cases precluded the hope of any benefit from attempted excision

Treatment of Postoperative Complications N A Johanson Seattle —p 221

Dislocation of Cervical Vertebrae —In Anderson's case there was an extreme dislocation of the fourth on the fifth cervical vertebra without any cord lesions Treatment instituted in this case was a combination of the manipulation and fixation methods After a hazardous attempt to reduce the dislocation by manipulation under ether proving unsuccessful, resort was had to the slower and more conservative method of casts and braces For several days before an anesthetic was given, about 20 pounds traction was applied to head by means of Sayre's bandage While under ether the most strenuous efforts were made to reduce the dislocation under guidance of a bedside roentgen-ray machine but without results either for better or worse The immobilization method was the only alternative, so a cutlass of plaster-of-Paris was applied Neck was kept in casts for three months when a brace was applied which he has been wearing about a year He now has no pain complains only of some stiffness in neck, no nerve complication at all, and there never has been in spite of marked dislocation Patient is gradually being weaned away from the brace

Food Value of Philippine Bananas W Salvador Manila —p 363

Schick Reaction in Filipinos —In all 1,030 persons of various ages were tested by Gomez, Navarro and Kapauan Eighty-eight or 8 5 per cent, were positive Most of the positives were found during the first eight years of life, especially during early infancy and childhood The number of positives decreased considerably from the age of 8 years up to the adult period The females, as a general rule, showed a greater number of positive reactions than the males, they averaged 14 per cent of the total number of females examined, whereas the males only showed 5 8 per cent of positives

Food Value of Philippine Banana —The components that Salvador found make up the edible portion of the Philippine banana include water, fat, protein, carbohydrates, organic acids, and mineral matter Of these water is hardly to be considered as a nutrient, though it plays an important part in food as a diluent and solvent The fat, protein and carbohydrates contribute in varying degree to the supply of fuel for the production of heat and energy Besides this universal function the fat and the carbohydrates serve especially to furnish fatty tissue in the body, while the protein is the chief source of muscular tissue The organic acids are minor, though important, constituents of food Because of their conversion into carbonates within the body, they are useful in furnishing the proper degree of alkalinity to the blood and to the various other fluids, besides being of particular value as appetizers The mineral or inorganic salts are necessary to supply material for the teeth and bones, besides having an important place in the formation of hemoglobulin in the blood and in the cellular structure of the entire body Philippine bananas, as shown by the analyses, are essentially carbohydrate foods, the percentages of protein and fat being correspondingly low Their nutritive value lies chiefly in the sugars they contain although the acids and salts exercise an important function in the digestive processes The sugars are present, both as reducing and as sucrose Although the banana is rich in carbohydrates, its low content of protein indicates that it is not a well-balanced ration but should be eaten with beans, peas, or other vegetables rich in protein or with lean meat in order to secure a proper quantity of protein in the diet

*Isohemagglutination S C Dyke —p 146

Relative Value of Human and Guinea Pig Complement in Wassermann Reaction A. F Hayden —p 151
*Experimental Immunization Against Bacillus Dysenteriae (Shiga) and Its Toxins S Kanai —p 158

Infection of Lice with Rickettsia Prowazeki—The injection of lice with a concentrated emulsion of platelets obtained by fractional centrifugalizations of the blood of a typhus infected guinea-pig, according to Bacot and Segal, affords a sure and quick method of obtaining the development of *Rickettsia prowazeki* in these insects The lice thus infected can be used to convey typhus fever to fresh guinea-pigs The parallel development of typhus virus and *Rickettsia prowazeki* in successively passaged guinea-pigs is demonstrated and also in lice infected from guinea-pigs after twenty-three blood or brain passages

Estimation of Diastase Content of Urine—The original technic for the diastase reaction is criticized by Dodds because it takes no account of the varying reaction of normal urine A modified technic is described whereby the urine is diluted with a phosphate buffer solution, thus bringing all urines to the optimum p_H before its starch-digesting power is tested Ammoniacal decomposition, by making the urine more alkaline decreases the diastatic power as determined by the old method, but has no effect on the method suggested Diastase tends to cling to urinary deposits, hence all urines should be well shaken

Etiology of Dental Caries—The examination of selected carious material by McIntosh, James and Lazarus-Barlow showed the constant presence of a definite type of bacillus Teeth left in contact with pure cultures over prolonged periods showed changes almost identical with those found in natural caries The bacilli, to which it is proposed to give the name *B acidophilus-odontolyticus*, in their resistance to and formation of acid resemble the "acidophilus" group of Moro, biologically, however, there are several points of difference

Isohemagglutination—Absorption tests performed by Dyke on serums of Groups II III and IV using corpuscles of Groups I, II and III confirm von Dungern and Hirschfeldt's hypothesis as to the distribution and nature of agglutinins and agglutinable factors in the four blood groups

Experimental Immunization Against Dysentery Bacillus—Attempts made by Kanai to secure, by subcutaneous and oral administration of killed vaccines a solid active immunity against the potent soluble toxin of *B dysenteriae* (Shiga), intravenously administered, have not been attended with the striking success realized in previous work when active immunity was sought to the live bacilli similarly administered Therefore, comparative estimates of the value of oral and subcutaneous methods in this connection are not at present possible

*Quinin Necrosis of Muscle P Figdor and D D' Pinnock —p 14
Blood at 100 Years of Age F G Macnaughton —p 14
Treatment of Erysipelas by Vaccines J R Russell —p 15

Diagnostic Value of Fractional Test Meals—The acidity curves plotted from fractional test meals Pemberton regards as being of some value in obtaining knowledge of the factors which modify the acidity Alterations in these factors bear some sort of relation to gastro-intestinal lesions, hence the acidity curves may throw some light on these lesions These curves seem divisible into at least six types of varying diagnostic value By comparison with other methods, the fractional test meal is at least admissible as an aid to diagnosis

Carbon Tetrachlorid Treatment of Hookworm Infestation—Nicholls and Hampton relate the case of a murderer under sentence of death who volunteered to take carbon tetrachlorid Six c c was given one hour after the midday meal, and the same day he passed four worms (*Ascaris lumbricoides*), thirteen days later this dose was repeated at 7 a m before any food had been taken The patient stated that at 11 45 he felt a little giddy and sleepy, but this soon passed The execution took place a week after the second dose, and a postmortem examination was made one hour after death No hookworms or ascarids were found in the intestinal tract Sections of his organs were examined microscopically, but showed no signs of degeneration of any kind Therefore, it is apparent that in single doses carbon tetrachlorid is a safe remedy The students of an agricultural school who were infested with hookworms received a dose of 3 c c of the drug at 6 30 a m before any food had been taken, no purgative was given after the drug was administered They were instructed to carry on their usual mode of life, and restrictions were not placed on their work, play, or diet Not one of them was inconvenienced by the drug, and they all continued their day's work All stools passed for three days after treatment were collected and carefully searched for worms A total of 719 hookworms, or an average of thirty-six for each student, were recovered Besides these hookworms, thirteen *Ascaris lumbricoides* were passed Microscopic examination of fecal specimens ten days after treatment showed ova of hookworms in only two specimens, which indicates that 90 per cent were cured Two-thirds of the worms were passed on the second day after the treatment Other observations made show that the drug may be administered safely in doses of from 10 to 20 minims to children 3 and 4 years of age, even when they are seriously ill from various causes It aids the expulsion of *Ascaris lumbricoides* if it is followed by a purgative, but it is not as effective as chenopodium in killing this worm The drug does not seriously deteriorate on keeping Many children were given carbon tetrachlorid which had been stored in the laboratory for three years It is more valuable than chenopodium for campaigns against hookworm disease because (*a*) patients do not object to its taste, (*b*) it is not necessary to precede or follow the administration of it by a purge, (*c*) it is more efficient than chenopodium and has not the depressing effects of that drug, (*d*) it is much cheaper than any other drug that has been used, (*e*) it can be prepared in a high degree of purity, and a chemically pure preparation should always be used, (*f*) the person who is being treated can do his usual day's work

Quinin Necrosis of Muscle—The interest of the case cited by Figdor and Pinnock relates to the early treatment of the patient by intramuscular injections of quinin and its unusual sequel Necrosis took place, but in none of the other cases of quinin necrosis recorded has there been, as in this case, a definite separation and encysting of the necrosed muscle

Delouser J H Ingram Peking —p 225
Delousing with Special Reference to Ingram Apparatus C W Young Peking —p 230
Renal Function Tests H W S Wright Tsinanfu —p 242

Operation for Cirrhosis of Liver—Ludlow makes an incision in the median line between the umbilicus and symphysis pubis A tube is inserted and the fluid removed by suction or syphonage after which the whole field of the abdomen is explored The omentum is then sutured with catgut to the parietal peritoneum over as extensive a surface as possible A small amount of the omentum is then drawn out from the upper part of the wound and tucked under the skin and stitched in place with catgut sutures—a combination of the Talma and Narath and Vander Veer operations On the patient's return to the ward, the tube is connected with a bottle for continuous drainage which is usually kept up for a week The fact that there was no operative or postoperative mortality in the last five cases and that the patients were at least much improved, Ludlow thinks, warrants the continuance of the method

Sensitizing Action of Thyroid Extract for Epinephrin—Ono's experiments show that an active principle of thyroid sensitizes the heart of cold blooded animals (toad) and the blood vessels of warm blooded animals (cow) for the action of epinephrin

Experimental Inoculation of Mouse Carcinoma—The result of the inoculation of the mouse carcinoma of Flexner's type into the subcutaneous tissue of mice is entirely negative But the intracranial transplantation of the same tumor into the same animal gives apparently positive results in more than 64 per cent The growth of the tumor tissue inoculated is infiltrative though very slowly The vital reaction in the tissue around the growing tumor tissue is generally sluggish Hypodermic transplantation of the mouse carcinoma of Flexner's type into pigeons is absolutely negative, but it gives apparently positive results in the brain of the same animals

Active Principle of Ginseng—Abe and Saito found that the substance in ginseng which has inhibitory action on blood sugar is not extracted by petroleum ether or ether, but by pure alcohol This active principle of ginseng is said to be a glucosid

Case of Eclampsia in Thirty Fourth Week Treated by Cesarean Section Mother and Child Living A W Owen—p 70
Case of Carcinoma of Cervix in Young Woman Following Gonorrhea S G Luker—p 71

Delayed Congenital Syphilis—Eight of the ten cases reported by Spackman occurred in full grown serving soldiers, whose ages were between 19 and 31 years, the two civilian patients were aged 17 and 16 years, respectively In the eight cases there were no signs of a syphilitic breakdown until the men were engaged in the strenuous work of war Further points of interest in these cases are that four out of eight soldiers were passed into the army as A 1—and that six out of the eight were actually serving in France when their syphilitic symptoms appeared, four of them being combatants in the front line Syphilis hereditaria tarda, Spackman says, is not a rare disease, and should be diagnosed more frequently than it is in adult life Aortitis or aneurysms may have a congenital origin and not be the result of acquired syphilis All cases of syphilis, congenital or acquired, should be placed in the hands of those competent to treat them, and if any permanent benefit is to be expected such treatment must be intensive and thorough Disease of the eye, in the form of interstitial keratitis, iritis or choroiditis often one of the earliest signs, is of great importance in early diagnosis

Diastase Reaction of Urine—Urines tested for diastatic activity Sladden says, should be brought to a standard hydrogen-ion concentration, preferably the optimum, p_H 6 7 In assessing results, the total day's excretion rather than the unit value alone should be considered Low diastase values definitely indicate nephritis as a rule, but not all nephritics (and notably pyelonephritics) have lowered values Not all types of pancreatic lesions cause excessive diastase output The test is of much value in dealing with toxemias of pregnancy and allied conditions

Carcinoid Tumor of Meckel's Diverticulum—Hicks and Kadinsky assert that no tumor of this nature has been recorded up to date as occurring in a Meckel's diverticulum The patient was a boy, aged 12 years, who complained of sickness and abdominal pain Seven weeks before admission he had had an attack of abdominal pain, vomiting and diarrhea lasting twenty-four hours The pain recurred about once a week for the next four weeks, and the attack lasted for an hour After this attacks became more frequent and were accompanied by vomiting A diagnosis of appendicitis was made and the patient operated on the same day At the operation the appendix, which was retrocecal, was found quite normal A small amount of pus escaped in the region of the cecum, which was edematous and thickened from the adherence to it of the distal end of an acutely inflamed Meckel's diverticulum The diverticulum was 3 inches long kinked and perforated, pus was present in the pelvis The paracecal glands were enlarged The diverticulum appendix and one gland were removed and the peritoneum drained The patient made a good recovery

Early Cesarean Section in Eclampsia—Owen believes that the 30 per cent mortality for cesarean section performed for eclampsia for the ten years 1911-1920 could undoubtedly be greatly reduced if prompter action were taken The interval between the first fit and the operation in his case was just three and a half hours

Carcinoma of Cervix Following Gonorrhea—Luker's case occurred in a secundipara aged 28, in whom carcinoma of the cervix followed an attack of gonorrhea contracted five months previously The occurrence of a carcinomatous growth during local treatment of the cervical canal for gonococcal cervicitis, Luker thinks supports the 'irritation' theory in that in this case there was the discharge and also the repeated application of antiseptics

Operation on Round Ligaments—In choosing the operation to be used, Powell says the method that promises the best results is one that conforms most closely to the following considerations Allows a thorough examination of the pelvis, utilizes the strong inner half (or more) of the round ligament, leaves no free band in the peritoneal cavity, leaves no weak spot in the broad ligament as a possible path for hernia, exercises a partially forward pull on the uterus allows for the future possibility of pregnancy, allows sufficient space for normal expansion of the bladder

Argyll Robinson Sign from Skull Trauma G Guillain and L Laederich —p 814
Tabes in Two Europeans from African Syphilis A Sezary and J Ahibert —p 816

The Sign of the Thyroid—Parisot and Richard injected thyroid extract and noted its effect on the heart in 17 cases of hyperthyroidism, in 11 with other thyroid disturbance, 32 with normal glands, and 12 with deficient thyroid functioning —72 in all The reaction evidently depends on whether the vagus or the sympathetic system happens to be most sensitized at the moment But one reaction was constant and capital in hyperthyroidism, namely, a pronounced slowing of the pulse, after the massive injection of thyroid extract They call *this the sign of the thyroid* The *systolic blood* pressure usually declined also, and the oculocardiac reflex was exaggerated They say that this sign of the thyroid deserves to rank with Goetsch's epinephrin sign and Porak's sign of excessive thyroid functioning They found it useful in determining or excluding the participation of the thyroid in pluriglandular disturbances

Painful Paralysis of Infants—When a child is learning to walk and it falls while its hand is being held by a larger person, the elbow gets a jerk that may displace the head of the radius a little The result is what Broca called painful pronation, and taught how to cure it by holding the forearm in supination and pressing on the head of the radius while the forearm is flexed on the arm The radius slips at once back into place A case is described in which the jerk of the elbow occurred while the babe was sitting in its perambulator It had hold of the top when the nurse pushed the carriage suddenly forward to escape a vehicle

Anaphylaxis to Bread—In Turrettini's case, Quincke's edema developed in a previously healthy woman of 52 The urine was free from albumin, and when no starchy food was taken there was no edema, but whenever she ate any bread the edematous swellings and urticaria returned Attempts to desensitize have had no or only transient effect, and the edema still returns as regularly as when the anaphylaxis first developed This was in December, 1920

*Arthroplastic Operations for Ankylosis V Putti —p 121
*Trauma of Wrist in Children R Massart and P Cahouat —p 133
*Perforation of Gastroduodenal Ulcers A Kotzareff —p 158
*Endoscopy of Neck of Bladder L Phelip —p 171
*Fracture of Semilunar Bone E Destot —p 178
*Clamp for Extraction of Fibromas H A Albertin —p 187

Arthroplasty for Ankylosis—Putti has now a record of 113 cases of operative mobilization of stiff joints, 10 of the jaws, 38 of the elbow, 17 of the hip, and 40 of the knee, with others in five other joints The great progress realized in this kind of operations is due to the practice of interposing a flap taken from the fascia lata He covers with a free flap of this kind both epiphyses, fastening the flaps in place with a few catgut stitches The joint must be freely exposed but without cutting the parts which preside over motion and weight bearing The reconstruction of the joint and the results are shown in a number of illustrations and the excellent outcome He never drains, but lays great stress on the necessity for traction on the distal fragment, the limb in a plaster splint The traction holds the parts of the joint apart, and he keeps it up for a month Passive movements are not begun till the tenth day They are done by the patient himself, with simple apparatus fastened to the bed To avoid any strain on the joint, it is best for the patient to make these passive movements without assistance, the physician merely supervising As soon as the wound has healed, Putti begins hot air treatment, at first with an electric apparatus and later with an alcohol heater This treatment has to be kept up for several months He does not regard massage as of much importance, believing that the electricity stimulates the principal muscles more effectually Mechanical treatment need not be begun till the twentieth day The old, simple Bonnet apparatus is very practical The patient should not bear his weight on the new joint until the thirtieth day These new joints pass through a critical period about a month after the operation, the joint may be stiff and a little painful The hot air treatment should be suspended for a few days, and only cautiously resumed Extra care for a longer time is required for the jaw and the knee The chances of success are better with the elbow, next the knee, the jaw and the hip

Trauma of the Wrist in Children—This profusely illustrated study of the wrist and its injuries is based on 377 cases of trauma of the wrist in children

Perforation of Gastroduodenal Ulcer—Kotzareff protests against an immediate gastro-enterostomy when a perforated ulcer has been sutured His reason for this protest is the assumption that chronic gastric and duodenal ulcers are caused by infection with a fungus, and by making another opening we invite the localization of this fungus at this point Askanazy's clinical and experimental research—in which Kotzareff cooperated—seems to have established that *Oidium albicans* is usually responsible for chronic ulcers In operating, measures must be applied to destroy the oidium in the stomach, duodenum and mouth, otherwise the pus in the peritoneum will be invaded Wherever there is a lesion in the mucous membrane the oidium is liable to take root. He urges search for the oidium in all ulcer cases and recognition of its causal action

The Functioning of the Neck of the Bladder—Phelip's endoscopic study of partial retention of urine has confirmed that the evacuation of the bladder does not depend merely on the opening and closing of the sphincter. There are four movements of the parts involved, and functional derangement from any one of these can be corrected by restoring this functioning to normal. This emphasizes the necessity for endoscopic analysis of the disturbances to allow correction before irreparable damage has been wrought.

Fracture of the Semilunar Bone—Destot's article is based on twenty-four cases.

Extraction of Fibromas—Albertin's illustrations show the double-pronged corkscrew device which he screws into the fibroma. The curving prongs aid in cutting out the fibroma while the hold is firm and solid and there is no hemorrhage where it is worked in. He says it is superior to all similar models, and anyone can make one like it for himself.

Secretion of Pepsin and Pepsinuria. Loeper and J Baumann—p 529
Metal Bands for Fractured Bones. A Lambotte—p 530
Pregnancy in the Tuberculous. F Dumarest and P Brette—p 531

Pepsin—Loeper and Baumann have been making a special study of the secretion of pepsin, and present data to show that in addition to its protein digesting function, it instigates certain nervous and vascular reactions. It reduces the blood pressure, stimulates peristalsis, and is essentially vagotonic. Hence when pepsin is secreted in excess or in inadequate amounts besides the purely digestive disturbances that result there may be general disturbances from the excess or the lack of pepsin. Much pepsin in the fasting stomach content testifies in favor of ulcer and true hypersecretion. The serum and urine of the normal fasting subject do not contain pepsin, but in case of ulcer large amounts of pepsin are found in both serum and urine. The constancy of this fasting finding contrasts with the variability after meals.

Metal Bands for Fractured Bones—Lambotte's modification of the Parham bands has already been described in these columns when published elsewhere (May 6, 1922, p 1424). A little slide fits over the band and holds the turned back end thus rendering it much more solid. Fifteen illustrations show Lambotte's band-passer, vice, etc.

Pregnancy in the Tuberculous—Dumarest and Brette report nine cases in which a pregnancy or even repeated pregnancies in tuberculous women seemed to have a favorable influence on their disease. They cite Lassegue's three cases in which pulmonary tuberculosis seemed to have been arrested by the pregnancy. Artificial pneumothorax has introduced a new element into the question, and they describe eight cases in which women with a lung in collapse passed safely through an apparently normal pregnancy. It seems in many of such cases that the arrest of menstruation has a decidedly favorable effect. In the progressive immunization of the race the children of parents with attenuated tuberculosis are the agents. When conceived during the phase of fibrous transformation of the tuberculous process, the child is born with defensive attributes and his progeny some day will triumph definitely over the tubercle bacilli. All biology teaches that nature does not know of and does not practice any other means of stamping out contagious diseases than by progressive immunization. The cases of tuberculosis in which a favorable outcome is more probable are those with pronounced reactions, and the focus in the lung has had a slow fibrous evolution.

Chemical Modifications of the Serum in the Course of Liver Disease. Biscons and Rouzaud—p 91
Hemiplegia with Hemichorea. A Remond and H Colombies—p 107
Current Topics. H Codlewski—p 111

Dietary Deficiencies—Mouriquand and Michel review the literature on the vitamins and the practical conclusions which their own clinical and experimental experience has confirmed. They warn not to hesitate to use cod liver oil freely, as indicated for children of all ages into puberty.

Chemical Changes in the Serum in Liver Disease—Biscons and Rouzaud found that the cholesterin and the bilirubin content of the blood showed promptly the effect of obstruction of the flow of bile. When the liver itself begins to suffer then the nitrogen and the sugar content soon show the effect also. During the congestion phase, the azotemia rises, but when the liver becomes seriously diseased, the azotemia declines. This decline may be masked, however, by uremia from retention by the kidneys. The ureosecretory index will reveal whether this is the case. Hypercholesterinemia is to gallstones what uricacidemia is to gout. Hemolytic jaundice on the other hand bears the imprint of hyperbilirubinemia. These two cycles are thus distinct but the liver is a factor in both. Chemical examination of the blood serum may thus give the clue in puzzling conditions, tracing to cholelithiasis certain stomach disturbances. In other cases the normal findings in cholesterin, glucose and urea exculpate the liver and warn to seek elsewhere for the cause of the disturbances which have been masquerading as disease of the liver. But it is in the early detection of liver disease that chemical examination of the blood is most instructive and salutary, prompt treatment enabling us to steer the liver into a safe harbor. A course of alkaline mineral waters for instance has more chance to reduce the hypercholesterinemia and restore normal conditions in the liver, the less advanced the liver affection.

Pathology of the Autonomic Nervous System. H Roger—p 193
Arsphenamin by Subcutaneous Injection. J Minet and R Legrand—p 230
Recent Literature on Tuberculosis. H Godlewski—p 244. Cont'd

The Phenomena of Shock by Contact—Kopaczewski describes the features which differentiate shock from injection of a suspension from shock from injection of a colloid and from the shock of anaphylaxis. Each of these three forms of shock by contact requires different treatment, measures to prevent flocculation or lysis or coagulation. He emphasizes that there are numbers of well tried substances at our disposal for this capable of reducing the surface tension or augmenting the viscosity without any risk. Among the antilytic substances cholesterin has been the best studied.

Cardiovascular Complications of Malaria—The treatment of old heart and aorta lesions for which malaria is responsible has to be addressed merely to the heart. Quinin has no action on the dilatation of the heart once established from the influence of the malaria. The gravity inherent in all heart affections is enhanced by the debility from the malaria and the liability to new febrile attacks.

Is Gonococcosis Curable?—Lebreton is convinced that the gonococcus affects the genital organs more than the urinary organs in both men and women. It is not enough to clear the urethra of gonococci to insure that the infection has been eradicated. In 164 cases of chronic urethritis in which the urethral secretion seemed to be sterile under the microscope, cultivation of the semen revealed gonococci in 70 per cent. The sperma is evidently responsible in many instances for the infection of the wife when the husband has long been supposedly cured of his gonorrhea. An autogenous antigonococcus vaccine is often effectual in dislodging the gonococci in the

deeper organs He gives a series of six doses and then waits two weeks and repeats the series once or twice, as the most effectual method yet known for 'degonococcization" It proved successful in all but one of sixty-seven chronic cases thus treated, and this one would probably have been cured by a supplementary series The success was complete also in three cases of suppurating prostatitis, although five series were required in one case The cure was complete also in three cases of crippling gonococcus rheumatism and in a case of gonococcus pyelonephritis

Expression of Eyes as Sign of Syphilis—Chelmonski remarks that the most artistic artificial eye can always be told from a natural eye and the eyes of syphilitics have a certain aspect which tells the story of the infection The reactions of the pupils are less pronounced than normal, they may be oval, the anterior chamber may be flat, the cornea dull, the vessels constricted

*Early Traumatic Epilepsy P L Della Torre—p 349
*Hemostasis for Resection of Liver E Angeletti—p 400
Hernial Appendicitis A Milham—p 419
Cystic Protrusion of Ureter into Bladder R Cassanello—p 429
*Foreign Bodies and Leukoplasia in Kidney Pelvis C Romiti—p 449

Early Traumatic Epilepsy—This is a study of nine operative cases in the war wounded Epilepsy developed in 9 per cent of those wounded in the head during Della Torre's early experience in the war He gives an illustration of the regions of the skull in which trauma is most liable to be followed by epilepsy Seven of the nine were cured by his operation and all have resumed their regular occupation although two still have attacks of the traumatic epilepsy

Hemostasis in Resection of the Liver—Angeletti had occasion to remove a large tumor in the liver of a woman of 51 His assistant arrested the hemorrhage by compression with his fingers while Angeletti cut a long strip, over 1 cm wide, from the aponeurosis of the rectus muscle on each side of the incision, taking up a little of the muscle with it Each strip was then laid on the liver close to the raw edge, the two strips thus encircling the entire raw area, a little back from the edge A series of seven or eight U stitches were then taken, traversing the upper strip, the whole of the liver and the under strip, and back again The U sutures were symmetrical, and when they were tied the tissues forming the edge of the raw expanse were drawn close enough together to insure hemostasis Another row of sutures was then taken to draw the edges, the sides of the wedge, together and thus close the gap in the liver He describes other ways to utilize this principle of an aponeurosis strip for a border to suture into after resection of the liver Seven illustrations show the exact technic In future he would not attempt to drain The aponeurosis and muscle strip border possibly might be sutured in place before the resection is begun He reviews the entire history of attempts at bloodless surgery of the liver crediting the first successful attempt to an Italian surgeon in 1716

Foreign Bodies in Kidney Pelvis—Hydronephrosis of probable congenital origin became infected and required long surgical treatment in the course of which four fragments of drainage tubes were left in the kidney pelvis The young man was finally cured by nephrectomy The case reaffirms the necessity for postoperative supervision When the care after operations is left to the family, we can scarcely escape such mishaps

*Intra Uterine Transmission of Scarlet Fever O Cozzolino—p 481
*Primary Progressive Myopathy Four Cases L Auricchio—p 488
Acute Endocarditis in Nursling with Heart Defect A F Canelli—p 495

Intra-Uterine Transmission of Scarlet Fever—Cozzolino relates that the mother died the fifth day of scarlet fever that appeared after she entered the maternity for the childbirth Her child of 21 months died the second day of fulminating scarlet fever that had developed six days after the death of the mother The new-born child developed scarlet fever when 20 days old The infant's urine had been pathologic for a day or two, and the child the nineteenth day presented the clinical picture of classic hemorrhagic glomerular nephritis for which no cause could be discovered except the scarlet fever He thinks the circumstances render intrauterine transmission of the scarlet fever extremely probable

Primary Progressive Myopathy—In Auricchio's case the four brothers under 13 presented different stages of the primary progressive myopathy No benefit was apparent from vigorous thyroid or antisyphilis treatment

*Relations Between Asthma and Tuberculosis E Bufalini—p 709
*Epidemic Lymphadenitis A Sala—p 717
*Treatment of Anthrax T Biancheri—p 718
*Treatment of Anthrax L Conti—p 720
*Postencephalitic Parkinsonism T Silvestri—p 721

Asthma and Pulmonary Tuberculosis—Bufalini tabulates the findings in 10 men and 12 women with asthma, recording the heredity, the antecedents, the response to tuberculin tests the findings in the lungs, etc In 15 of the 22 some affection of the respiratory tract had preceded the asthma, but only a few had been tuberculous Tuberculin tests were positive in 19, active pulmonary tuberculosis was evident only in one instance

Epidemic Lymphadenitis—Sala relates that since the epidemic wave of influenza and epidemic encephalitis, there has been a local epidemic of jaundice in his region (900 cases) This was followed last August by an epidemic of buboes Twenty cases were observed the glands in the groin swelling and sometimes ulcerating This lymphadenopathy suggested bubonic plague at first All the patients recovered after a course of three or four months Vanni isolated a micrococcus from the glandular lesions which reproduced the disease in guinea-pigs and other animals

Serotherapy of Anthrax—Biancheri protests against incision of the focus as intramuscular or subcutaneous injection of the antiserum has always proved effectual in his experience unless the patient was moribund when first seen He injects 60 c c at first and then 20 c c each day After the local inflammation has entirely subsided he excises the eschar to hasten the healing Conti on the other hand, excises the lesion completely with a deep circular incision The mortality was 3 33 per cent in sixty cases treated in this way while it was 20 per cent in twenty treated by a crucial incision

Paradoxic Sign of Postencephalitic Parkinsonism.—Silvestri reports two striking cases of the phenomenon to which Masci called attention as was summarized here July 8, 1922, p 168 In Silvestri's cases the parkinsonism was extremely pronounced in the girl of 13 and the young man at all times except when the girl was dancing and the young man was bicycling The movements of the dancing girl and the speeding bicyclist seemed to be normal in every respect Abbruzzetti reported this paradoxic behavior in 1920 and Tilney and Souques have also called attention to it the latter styling it paradoxic kinesia.

*Cause of Adenoids P Brisotto—p 409
A Precancer Lesion of the Lip G Anzilotto—p 411
*Influence of Pituitary Extract on Bladder M G Serdinkoff—p 413
Simplification of Daneey Ureometer G Candido—p 417

Cause of Adenoids—Brisotto found inherited syphilis certain or very probable in 56 per cent of 150 children with adenoids, and tuberculosis in 24 per cent In 8 per cent there was both tuberculosis and inherited syphilis Hypothyroidism was evident in 6 per cent, and in 2 per cent there was a history of alcoholism or consanguineous marriages He theorizes that the adenoid vegetations represent merely a defensive reaction carried to excess Resection of the adenoids is only symptomatic treatment it is useful only when associated with treatment to modify the general condition of the bone and lymphatic systems

Influence of Pituitary Extract on the Bladder—Serdinkoff calls attention to the remarkable efficacy displayed by two injections of pituitary extract in a case of retention of urine from paresis of the bladder secondary to pyelonephritis from metritis in a woman of 32 Spontaneous micturition had been

impossible for thirty-five days The bladder had been enormously distended before the retention was recognized and the paresis had developed the seventh day of the retention She had had a similar attack of retention of urine three years before with cystitis, and there was a history of three or four abortions without appreciable cause The tonus of the smooth muscle of both uterus and bladder was evidently abnormal, and this was effectually combated by the pituitary treatment

Syphilitic Heart Disease S A Meza and J Paulis —p 199
The Book of the Plague A D 1599 I Mercado —p 200

Fracture of the Clavicle—Soler Julia gives an illustrated description of the Esquerdo plaster bandage which leaves the hand and elbow joints free and interferes only slightly with the use of the shoulder Flannel is cut double in the shape of half of a man's vest Each half is coated with plaster on a table and then one half is laid on the other the plaster between and this half-vest is then fitted over the trunk packing the axilla thick with cotton Broad bands of glued tarletan are then wound around the trunk and shoulder, molding the plaster cast to the back and front and forming a stiff collar that forces the head up a little and toward the sound side It forms also a stiff sleevelet that prevents the arm from being moved forward The cotton in the axilla raises the shoulder Ordinary use of the arms is not interfered with the boy can play ball with both hands the housemaid keep on with her duties and the cast can be removed and massage commenced the twenty-fifth day in the young

Syphilitic Heart Disease—Meza and Paulis say that Cesa-Bianchi's recent discovery of spirochetes in the heart in inherited syphilis confirms the necessity for suspecting syphilis in all kinds of heart disturbances They list twelve different forms of heart disease that it may assume and emphasize that electrocardiography is one of the most reliable means to detect latent mischief of this kind By prompt treatment we may avert irreparable damage and sudden early death

*The World War Against Tuberculosis M Becerro de Bengoa —p 65
Fractures of Anterior Arch of Atlas A di Lorenzo —p 313
*Lithopedion C Legnani —p 16
Present Status of Bismuth Treatment of Syphilis Jose Mas —p 20

Failure of the World War Against Tuberculosis—Becerro de Bengoa asserts that the death rate from tuberculosis is constantly increasing notwithstanding the great concerted efforts against it He outlines a system of tactics that would exterminate tuberculosis sooner or later His *formula de la victoria* is to have the entire populace examined for tuberculosis once a year at public expense with segregation of the 'open cases in special public or private sanatoriums or colonies until they are no longer contagious or they die the breadwinners to be given a pension until recovery or death

Lithopedion—In Legnani's case the fetus weighed 1 000 gm and the size corresponded to term It was found free in the abdominal cavity over four years after the last fetal movements had been felt The woman had borne two children before

deeper organs He gives a series of six doses and then waits two weeks and repeats the series once or twice, as the most effectual method yet known for "degonococcization" It proved successful in all but one of sixty-seven chronic cases thus treated, and this one would probably have been cured by a supplementary series The success was complete also in three cases of suppurating prostatitis, although five series were required in one case The cure was complete also in three cases of crippling gonococcus rheumatism and in a case of gonococcus pyelonephritis

Expression of Eyes as Sign of Syphilis—Chelmonski remarks that the most artistic artificial eye can always be told from a natural eye, and the eyes of syphilitics have a certain aspect which tells the story of the infection The reactions of the pupils are less pronounced than normal, they may be oval, the anterior chamber may be flat, the cornea dull, the vessels constricted

Hernial Appendicitis A Miliani—p 419
Cystic Protrusion of Ureter into Bladder R Cassanello—p 429
*Foreign Bodies and Leukoplasia in Kidney Pelvis C Romiti—p 449

Early Traumatic Epilepsy—This is a study of nine operative cases in the war wounded Epilepsy developed in 9 per cent of those wounded in the head during Della Torre's early experience in the war He gives an illustration of the regions of the skull in which trauma is most liable to be followed by epilepsy Seven of the nine were cured by his operation and all have resumed their regular occupation although two still have attacks of the traumatic epilepsy

Hemostasis in Resection of the Liver—Angeletti had occasion to remove a large tumor in the liver of a woman of 51 His assistant arrested the hemorrhage by compression with his fingers while Angeletti cut a long strip, over 1 cm wide, from the aponeurosis of the rectus muscle on each side of the incision, taking up a little of the muscle with it Each strip was then laid on the liver close to the raw edge, the two strips thus encircling the entire raw area, a little back from the edge A series of seven or eight U stitches were then taken, traversing the upper strip the whole of the liver and the under strip, and back again The U sutures were symmetrical, and when they were tied the tissues forming the edge of the raw expanse were drawn close enough together to insure hemostasis Another row of sutures was then taken to draw the edges, the sides of the wedge, together and thus close the gap in the liver He describes other ways to utilize this principle of an aponeurosis strip for a border to suture into after resection of the liver Seven illustrations show the exact technic In future he would not attempt to drain The aponeurosis and muscle strip border possibly might be sutured in place before he resection is begun He reviews the entire history of attempts at bloodless surgery of the liver crediting the first successful attempt to an Italian surgeon in 1716

Foreign Bodies in Kidney Pelvis—Hydronephrosis of probable congenital origin became infected and required long surgical treatment in the course of which four fragments of drainage tubes were left in the kidney pelvis The young man was finally cured by nephrectomy The case reaffirms the necessity for postoperative supervision When the care after operations is left to the family we can scarcely escape such mishaps

*Intra Uterine Transmission of Scarlet Fever O Cozzolino—p 481
*Primary Progressive Myopathy Four Cases L Auricchio—p 488
Acute Endocarditis in Nursling with Heart Defect A F Canelli—p 495

Intra-Uterine Transmission of Scarlet Fever—Cozzolino relates that the mother died the fifth day of scarlet fever that appeared after she entered the maternity for the childbirth Her child of 21 months died the second day of fulminating scarlet fever that had developed six days after the death of the mother The new-born child developed scarlet fever when 20 days old The infant's urine had been pathologic for a day or two, and the child the nineteenth day presented the clinical picture of classic hemorrhagic glomerular nephritis for which no cause could be discovered except the scarlet fever He thinks the circumstances render intrauterine transmission of the scarlet fever extremely probable

Primary Progressive Myopathy—In Auricchio's case the four brothers under 13 presented different stages of the primary progressive myopathy No benefit was apparent from vigorous thyroid or antisyphilis treatment

*Relations Between Asthma and Tuberculosis E Bufalini—p 709
*Epidemic Lymphadenitis A Sala—p 717
Treatment of Anthrax T Biancheri—p 718
*Treatment of Anthrax L Conti—p 720
*Postencephalitic Parkinsonism T Silvestri—p 721

Asthma and Pulmonary Tuberculosis—Bufalini tabulates the findings in 10 men and 12 women with asthma, recording the heredity, the antecedents, the response to tuberculin tests the findings in the lungs, etc In 15 of the 22 some affection of the respiratory tract had preceded the asthma, but only a few had been tuberculous Tuberculin tests were positive in 19 active pulmonary tuberculosis was evident only in one instance

Epidemic Lymphadenitis—Sala relates that since the epidemic wave of influenza and epidemic encephalitis, there has been a local epidemic of jaundice in his region (900 cases) This was followed last August by an epidemic of buboes Twenty cases were observed, the glands in the groin swelling and sometimes ulcerating This lymphadenopathy suggested bubonic plague at first All the patients recovered after a course of three or four months Vanni isolated a micrococcus from the glandular lesions which reproduced the disease in guinea pigs and other animals

Serotherapy of Anthrax—Biancheri protests against incision of the focus as intramuscular or subcutaneous injection of the antiserum has always proved effectual in his experience, unless the patient was moribund when first seen He injects 60 c c at first and then 20 c c each day After the local inflammation has entirely subsided he excises the eschar to hasten the healing Conti on the other hand, excises the lesion completely with a deep circular incision The mortality was 3 33 per cent in sixty cases treated in this way, while it was 20 per cent in twenty treated by a crucial incision

Paradoxic Sign of Postencephalitic Parkinsonism.—Silvestri reports two striking cases of the phenomenon to which Masci called attention as was summarized here July 8, 1922, p 168 In Silvestri's cases the parkinsonism was extremely pronounced in the girl of 13 and the young man at all times except when the girl was dancing and the young man was bicycling The movements of the dancing girl and the speeding bicyclist seemed to be normal in every respect Abbruzzetti reported this paradoxic behavior in 1920 and Tilney and Souques have also called attention to it, the latter styling it paradoxic kinesia

*Cause of Adenoids P Brisotto—p 409
A Precancer Lesion of the Lip G Anzilotto—p 411
*Influence of Pituitary Extract on Bladder M G Serdinkoff—p 413
Simplification of Dancey Ureometer G Candido—p 417

Cause of Adenoids—Brisotto found inherited syphilis certain or very probable in 56 per cent of 150 children with adenoids, and tuberculosis in 24 per cent In 8 per cent there was both tuberculosis and inherited syphilis Hypothyroidism was evident in 6 per cent, and in 2 per cent there was a history of alcoholism or consanguineous marriages He theorizes that the adenoid vegetations represent merely a defensive reaction carried to excess Resection of the adenoids is only symptomatic treatment, it is useful only when associated with treatment to modify the general condition of the bone and lymphatic systems

Influence of Pituitary Extract on the Bladder—Serdinkoff calls attention to the remarkable efficacy displayed by two injections of pituitary extract in a case of retention of urine from paresis of the bladder secondary to pyelonephritis from metritis in a woman of 32 Spontaneous micturition had been

impossible for thirty-five days The bladder had been enormously distended before the retention was recognized and the paresis had developed the seventh day of the retention She had had a similar attack of retention of urine three years before with cystitis, and there was a history of three or four abortions without appreciable cause The tonus of the smooth muscle of both uterus and bladder was evidently abnormal and this was effectually combated by the pituitary treatment

Sclerosis of Neck of Bladder F P Manchego —p 33
Correction of Perforation of Palate F La Torre —p 42
The Prehemorrhagic Stage in Typhoid A Ricaldoni —p 48

Sclerosis of Neck of Bladder—Manchego remarks that this condition is frequently mistaken for hypertrophy of the prostate in the elderly and for a stricture in the urethra in younger men In some of the six cases he describes this mistake was made in two cases there were polyp growths bedsides Infection is the rule because the catheter has to be used early The extreme difficulty in voiding urine contrasts with the ease with which even large instruments can be passed into the bladder Systematic dilation always improves, and resection of the fibrous tissue cures completely in 75 per cent of the cases Buerger's method of procedure is described In two cases Pazos Varela found that the neck of the bladder and upper urethra formed a stiff sheath requiring resection of the internal sphincter One of Manchego's patients was left with incontinence after the operation, but this was cured by resecting a fibrous band which had formed In two cases, time and efforts had been wasted on the mistaken diagnosis of hypertrophy of the prostate A huge fistula was left

Perforation of Palate—The syphilitic bone and mucous membrane lesion healed under treatment, and the defect was closed by suture and a prosthesis

Farm Colony for the Chronic Tuberculous F Cornil —p 773
*The Extinction Sign of Scarlet Fever D J Rojo —p 776

Indications in Dystocia—Boero refers to cases in which delivery is impossible on account of the defective development of the lower segment of the uterus The cervix feels like a cylinder, 5 or 6 cm long with three rings slipped over it The upper ring is so rigid that any attempt to deliver by the natural route is sure to tear the uterus The presenting fetus is high, almost unreachable from the vagina This form of dystocia is seldom recognized until late after the ineffectual labor contractions have long continued He has had this form of dystocia in women who had never had any trouble in former pregnancies The lower segment of the uterus had been vigorously cauterized in some of the cases he describes and he incriminates the cicatricial changes left from this or from curetting, as impeding the normal stretching of the cervix It differs in several respects from the dystocia for which spasm of Bandl's ring is responsible The ineffectual labor contractions merge into tetanization, and this passes into a phase of rigid retraction The tissues in this phase tear easily In five of the six cases described, the uterus ruptured during the efforts to deliver the fetus by the normal route even when the fetus had been dismembered

Variations in Weight of Children—Navarro records the variations in weight of 110 children given various tonics He is inclined to ascribe the remarkable gains made by some of the children, in large part, to the mental impressions from the weighing and attention otherwise and urges systematic weighing as a means to rouse the appetite and interest of children in their physical development

Partial Resection of Bladder—In Salleras' case the cystoscope showed an ulcerated tumor, 3 cm in diameter high in the bladder The first symptom had been hematuria in the man of 52 The hematuria returned occasionally during the following two months and there had been slight pain just above the symphysis, and the weight declined Salleras did not attempt endovesical measures but resected that portion of the bladder wall with the myo-epithelioma and the adherent peritoneum The health has been perfect during the three years to date Attempts at electrocoagulation would have been disastrous as it would have been impossible to reach the entire tumor with it

Diagnostic Blanching or Extinction Phenomenon in Scarlet Fever—Rojo's experience has confirmed the specific and reliable nature of the Schultz-Charlton phenomenon in the differential diagnosis of scarlet fever In his eighteen cases it was positive in nearly 78 per cent and constantly negative in the four cases of eruptions of other nature It was positive by the second day in fourteen of the eighteen scarlet fever children and allowed their prompt isolation The test is made with 0.5 or 1 c c of normal human serum injected intradermally where the eruption is most pronounced. The eruption disappears completely in a zone from 2 to 10 cm. wide around the point of injection in case of a positive response

Gas Gangrene of the Uterus—Brütt describes six cases of physometra from puerperal gas gangrene infection of the uterus In one case the fulminating gas gangrene infection proved fatal in thirty hours from the stormy onset In the second case anaerobic streptococci must be incriminated for the fatal complicating peritonitis and pneumonia in another case two weeks after the operation The uterus was removed in all the cases but the conditions were already beyond help in all but one case In another woman, a gangrene inducing metritis was the work of anaerobic streptococci alone Peritonitis always accompanied the gas gangrene With lymphangitic or thrombophlebitic sepsis, the fulminating course renders any operation futile

Mechanical Dilatation of the Uterine Cervix—Stephan calls attention to an old and forgotten dilator which he thinks is superior to all similar instruments in vogue The two blades are connected with a spring forming a half circle which holds the blades at rest, slanting outward about 5 cm. apart The blades are closed and held with forceps as the instrument is introduced The spring forces the blades apart and they stretch the lumen to 5 cm at the upper ends of the blades In his two and half years experience with it there was never any injury except occasionally a slight erosion at the internal os where the blades spread farthest apart The shape of the dilatation is the physiologic shape

The Metabolism with Spleen and Liver Disease—In seven of the nine cases Grafe tabulates, the spleen was very much enlarged, in the other two the liver was extremely pathologic Two of the splenomegaly cases were of the Gaucher type and one was cured by splenectomy Four were of the Banti type The temperature was normal or subnormal, but the

basal metabolism in all was abnormally high True primary cirrhosis of the liver, even when accompanied by enlargement of the spleen does not seem to send up the basal metabolism, while it is always high with splenomegaly of the Gaucher and Banti types "When the gas exchanges in a case of splenomegaly show the basal metabolism within normal range then splenectomy is contraindicated, as there is no toxic element to be eliminated by removing the spleen"

Influence of Muscular Exercise on Combustion of Sugar in the Diabetic—Grafe and Salomon report research on nine diabetics which showed that the combustion of sugar increased absolutely during exercise, but relatively it dropped materially The greater expenditure of energy must have been at the expense of the fat In conclusion they remark that all such experiences confirm the truth of the saying that fatigue is a sensitive and reliable gage of the injury of the body by any disease process

High Blood Pressure Without Kidney Involvement—Kulbs has found that there is a comparatively large number of patients with high blood pressure without clinically demonstrable affections of the kidneys In fact, the number seems to be increasing He discusses a series of 288 cases The working class does not seem to be affected as much as the professional or educated circles The causal factors seemed to be psychic excitement the climacteric syphilis, nicotine, alcohol, obesity, gout, and organic heart disease The majority of the patients improved (reduction to from 150 to 160 mm of mercury) under treatment proper rest periods, restriction of salt venesection small doses of digitalis, and potassium nitrate As a rule the subjective symptoms were relieved and the physical and mental capacity were improved

Conservative Operation on Esophageal Diverticulum.—Konig has tried a conservative operation on esophageal diverticulum in two cases He thinks that it is indicated at least in weak patients who could scarcely survive the radical removal of the sac, and that after more extensive trial, it may prove to have still wider indications in order to avoid the element of danger in the more radical operation in which the mortality ranges around 6 or 8 per cent The sac of the diverticulum is exposed and dissected free The contents are pressed out The flabby folded sac is drawn up laterally and sutured to the periosteum of the hyoid bone in its posterior portion To make the fixation still more secure he draws the loose sac up under the anterior portion of the omohyoid muscle, which on that account must be left intact it is also fastened to this muscle by a few stitches If the sac is sufficiently long this gives a very firm fixation and the omohyoideus helps also in relieving the sac of its contents Local anesthesia is employed The sac remains but the main thing is that food does not stagnate in it

Roentgen Irradiation of Hypophysial Tumors—Kontschalowsky and Eisenstein state that, in view of the fact that attempts at operative removal of tumors of the hypophysis result still in a very high mortality, recurrences also being very common since in many cases the operator does not succeed in removing the whole tumor roentgen irradiation which with cautious technic is not dangerous and usually gives good results, is to be preferred Only in cases in which roentgen irradiation proves useless (mostly colloidal cysts) and the eye symptoms and the severe headaches become alarming should an operation be undertaken as a last resort

Ecthyma Gangrenosum—In Dudden's three cases of ecthyma gangrenosum the pyocyaneus seemed to be solely responsible The children were 5 and 7 months and 4 years old, and none survived The gangrenous affection was on the back or seat or both, and it had followed pneumonia in all In another child, the pyocyaneus had induced lesions on the stomach and intestine mucosa which resembled those on the skin in his cases Irritation from urine stools and sweat should be warded off in prophylaxis with weakly children Hydrotherapeutic procedures might be given a trial, as well as symptomatic measures In the older child a tendency to retrogression of the skin lesions was evident toward the last, but the pyocyaneus was cultivated from the spinal fluid

The Own Urine Reaction in Tuberculous Children—The verdict was decidedly unfavorable after repeated examination of sixty seven children over long periods

Chemical Analysis of Infants' Brains—The infants analyzed in the group here reported had all died from toxicosis Nothing differing essentially from the findings in the brains of infants dying from other causes could be discovered

Serodiagnosis of Scurvy—Leichtentritt and Zielaskowski have been studying in human blood the normal protecting influence against trypanosoma infection in animals This trypanocidal property was found in human blood and the blood of apes by Laveran in 1902 but it has wide individual differences The suggestion is here made that these individual differences may be due to the resisting powers of the organism at the moment If this is accepted then the inference follows that the intensity of the trypanocidal action may serve as a gage for the resisting powers In the prematurely born, the children suffering from infection or from lack of vitamins the resisting powers are at such a low ebb that the production of the trypanocidal substance is temporarily in abeyance Hence the negative response to tests for this substance may aid in the differential diagnosis and in the grouping of certain maladies, reveal their connection

Research on the Treatment of Anemia by Autotransfusion of Blood—Furukawa states that the problem of rejuvenation of the blood supply of the organism entered upon a new stage when Kasys Naswitis made his researches to determine whether Haberlandt's observations on plants with respect to the causation of increased cell proliferation by so-called wound hormones would hold good for the higher mammals and more particularly man Naswitis method of experimentation follows Blood was taken from a subject and was either made incoagulable or was defibrinized It was then

placed in a freezing mixture and allowed to freeze, in order to destroy the blood cells It was now thawed out and permitted to stand for several hours at room temperature It was afterward heated to body temperature and was reinjected intravenously or intramuscularly into the same subject from whom it was taken The result was a considerable increase of red blood cells which could be noted in the course of several days The treated subject received in addition no other substance from any donor Only his own blood was reinjected in a changed form sometimes without fibrin, in any event after it had lost something of its original character Nevertheless hematopoiesis was favorably influenced Furthermore Naswitis was able to show that the good effect was associated with or dependent on the fact that the blood had undergone changes or that certain substances had been removed Through the partial destruction of the blood, irritative or stimulative substances are produced therein which excite to activity the hematopoietic or blood producing organs or regions Following Haberlandt's terminology with regard to plants Naswitis names these substances the "wound hormones' of the blood These wound hormones have nothing to do with the hormones of the endocrine glands In order to test the claims of Naswitis Furukawa brought about induced anemia in rabbits and dogs by injections of phenylhydrazin When the anemia had reached a certain degree he took from the experimental animal a small quantity of blood treated the blood after Naswitis method and reinjected it into the animal, either intravenously or subcutaneously The result was an increase of red blood cells Before the frozen and thawed blood is reinjected, it must be allowed to stand at least from two to three hours at room temperature for defibrinated blood exerts a toxic effect unless it is permitted to stand several hours If it is reinjected too soon it will produce shock effects and may possibly cause death Furukawa holds that the relations of blood decomposition to renewed hematopoiesis in the normal body have been suddenly opened up by the Niswitis experiments The whole research has been done at the Pathology Institute at Berlin

Recent Literature on Social Hygiene H Ziemann —p 769

Gynecology and Obstetrics During the War—Mayer discusses the effect of war conditions on menstruation and childbearing There was a large number of cases in which a child was born during the war after years of supposedly irremediably sterile marriage Since the war the number of women who apply with complaints of sterile marriage is strikingly large He quotes Siegel's conclusions from 300 cases of conception during the soldier husband's brief leave namely, that between the first and ninth days after menstruation begins the offspring are boys and between the fifteenth and twenty-second days girls are conceived Between these two periods either girls or boys may be conceived but later than these periods between the twenty-third and twenty-eighth days, conception rarely occurs The question is still unsolved as to the phase of the ovum during which it becomes fecundated The menses do not return after the ovum is once embedded in the uterus but menstruation probably can occur during the days after fecundation of the ovum before it has grown large enough for embedding or has even reached the uterus

Injection Treatment of Hemorrhoids—For six years Boas has been treating hemorrhoids with injection of 96 per cent alcohol He here reiterates his assertions in regard to the almost certain success of this excellent method of treatment He declares that any treatment by injections must be regarded as equivalent to an operation To insure aseptic thrombosis, the patient must stay unconditionally in bed for four or five days Intra-anal hemorrhoids do not need drastic measures, they can be kept in control or cured with salves and diligent use of sitz baths The intrarectal ones must each be delivered outside the anus for diagnosis and treatment This can usually be accomplished by straining, if not, an enema of hot salt solution or glycerin will often answer the purpose. Direct stretching of the rectum wall relaxes the internal nodules and may induce paresis of the sphincter, this is liable also when specula are used Aspiration with a Bier vacuum glass has always proved the best means for drawing out the hemorrhoids The aspiration is continued after local anesthesia until the nodules are distended to the utmost and they do not collapse when the cupping glass is lifted Very small amounts of alcohol suffice even for the largest nodules, he does not inject over 10 or 20 drops (0.5 to 1 c.c.) It is important to have no alcohol on the tip of the needle when the nodule is pierced as otherwise the thin wall of the vein becomes necrotic He injects all the hemorrhoids at the one sitting beginning with the small ones as these are liable to slide back first There may be no inconveniences from the procedure or there may be a sensation of fullness as the hemorrhoids swell They must be reduced at once when all have been injected, smearing with liquid petrolatum pushing them up into the rectum as high as possible During the four or five days in bed only fluid food is allowed then a saline purge is given supplemented by an oil enema Even the first stool may be painless The factors that brought on the hemorrhoids in the first place must be kept under control He has had a return of hemorrhoids in only six of the 150 cases he has treated with the alcohol injections In two instances he repeated the injections once or twice When there is already prolapse of the hemorrhoids it is futile to waste time on palliative measures Profuse hemorrhage may occur even without hemorrhoids The only cure here seems to be complete extirpation of the entire hemorrhoidal plexus

Protein Therapy—R Schmidt of Prague was the one who introduced systematic parenteral injections of 5 c.c. of milk into therapeutics and he discusses its value in internal diseases Fischnig in eye disease and Buschke in skin and venereal diseases This shock treatment has 'thrown light on processes such as "protoplasma activation' "increased vital efficiency the healing fever," and the 'healing inflammation The organism seems to be thrown out of the balance which had allowed the disease to become installed Schmidt says that this shock treatment seems to be indicated whenever an acute inflammatory process has passed into a *torpid* chronic phase The parenteral injection induces a local reaction in the focus and has proved useful in torpid joint affections in tuberculous processes in bone and peritoneum, and even in fibrous and torpid febrile processes in the lungs Acute processes like erysipelas may also be remarkably favorably affected In the hemorrhage of typhoid the milk injection has proved an excellent hemostatic He says that neuralgia is another promising field, trigeminal and sciatic neuralgia, and asthma Stimulation of diuresis may occasionally be another indication for it Dragging subfebrile states may be transformed by it The same as tuberculin it may benefit in general paresis He adds that protein bodies may serve usefully as a sensitizing principle to enhance the action of organotherapy for example by combining thyroid treatment with the milk injections we might act more effectually on obesity In all forms of protein therapy he advises to begin with small doses not over 0.1 or 0.5 c.c. of milk, repeating the intragluteal injection on alternate days for four or five weeks with the same or larger doses The maximum he allows is 5 c.c. Slight focal and general reactions are desirable

Fischnig says that the effects of protein therapy in eye affections have been capricious fine results in some and no effect in others Nonmycotic iridocyclitis seems to benefit most and acute gonococcus conjunctivitis in the earliest stages

In skin and venereal affections Buschke says the healing process seemed to be hastened a little in some cases especially with gonococcus epididymitis and arthritis and he was impressed with the relief from the pain The local hyperemia may be [illegible] at on of [illegible] benefit He warns

that latent tuberculous foci are liable to flare up under it The complete retrogression of a bubo or other lesion was very seldom observed under it, and never when the gonococcus was involved

Operative Treatment of Primary Carcinoma of the Buccal Mucosa—Kuttner reports results in his series of 266 cases of primary cancer of the buccal mucosa There were 155 tongue cancers 35 carcinomas of the floor of the mouth, 15 of the mucous membrane of the cheeks 12 of the hard palate and 49 of the tonsils Histologically they were nearly all typical pavement cell carcinomas of the epithelium, there were only two instances of glandular cancer Sex incidence was as 81 to 19, men predominating The largest contingent of men was furnished by the 45-50 age group the largest percentage of women were of the 30 35 age group There were no patients under 20 only 4 between 20 and 30, 43 per cent of the patients were heavy smokers, 22 per cent (exclusively men) presented leukoplakia near the carcinoma Syphilis was demonstrable in 15 5 per cent of the cases, in 33 per cent chronic traumatic irritants, such as the sharp edges of carious teeth and the pressure of artificial teeth could be incriminated Most mouth cavities showed signs of neglect Sixty-one per cent of the patients were subjected to a radical operation 21 4 were inoperable from the start From the time local anesthesia was routinely applied the mortality from lung complications (until 1908 14 per cent) has been reduced to 4 4 per cent The operation consists of two distinct acts a most thorough eradication of the neck glands and the extirpation of the tumor sometimes in one sitting and sometimes in two These cancers are always very refractory and he regards 17 2 per cent of permanent cures in tongue cancer as better than the average result Only when early diagnosis is followed by early operation and no time is lost over useless diagnostic and therapeutic measures will the results be improved The mistake so often made in the presence of a positive Wassermann test, of ruling out carcinoma whereas the predisposition of syphilities, especially if they are heavy smokers to carcinoma of the mouth ought now to be widely known Roentgen irradiation has so far proved of little value Radium treatment which is said to have accomplished better results in America than roentgenotherapy cannot be used extensively in Germany for the present on account of the heavy expense involved

After-Treatment of Osteomyelitis with the Bier Constricting Band—Hofmann admits that he has gone a step further than Hartel and has treated (or tried to treat) not only chronic but also acute cases of osteomyelitis by the Bier method of passive hyperemia Of his twenty-five cases sixteen were chronic and nine acute affections In the chronic form the procedure gave very satisfactory results for the two principal claims shortening of the healing process and securing of a better looking scar, were fully substantiated He describes his technic in detail

Sedimentation of Red Corpuscles in the Prognosis of Chronic Pulmonary Tuberculosis—Dreyfus says that the suspension stability of the erythrocytes promises to become an important aid in determining the activity of a tuberculous process, furnishing a more exact and more reliable indicator in regard to the course of the infection in a given case than observation of the temperature curve

The Income in Relation to Tuberculosis C Flage —p 245
*Children in Tuberculous Families Braeuning and Hollmann —p 255
Thoracoscopy Unverricht —p 267
Mode of Action of Tuberculin H v Hayek and L Wieser —p 288

The Relations Between the Death Rate from Tuberculosis and the Income—Flugge concludes from numerous statistics cited that what determines the prevalence of tuberculosis is the frequency of intercourse between children and tuberculous adults in a contagious stage and this is often dependent on the income But it need not be he declares Droplet infection can be avoided in the homes of the poor as well as elsewhere with proper care Civilized communities have learned to bathe and change linen and use individual drinking glasses and a generation may come in which it will be considered a disgrace to shed droplets around When children are trained in this the spread of tuberculosis will be much restricted Great progress in arresting the disease may be expected with better feeding Dinners and suppers should be given the tuberculous with moderate incomes The best way to maintain the appetite is to sell or give tickets at the preventorium which will be honored at various eating houses allowing a choice Arrangements might also be made with the eating houses for delivery of the food at home The tickets should not cost more than an ordinary cheap meal, but should entitle the holder to an extra nourishing meal A wide field for useful effort is offered in these attempts to insure extra nourishing food for the tuberculous while striving to maintain their interest and appetite He declares in conclusion that the prevalence of tuberculosis and the death rate from it are entirely different values and cannot be used as if they represented approximately the same thing

Children in Tuberculous Families—Braeuning and Hollmann present evidence that it is possible to protect young children against infection from open tuberculosis in the homes of the poor The infant mortality at Stettin 1911-1919 was 17 per cent while it was this same figure among ninety-nine infants in poor families with open tuberculosis under the supervision of the tuberculosis dispensary workers The training to avoid droplet contact and dust infection has evidently borne fruit

Thoracoscopy—Unverricht's experimental and clinical research has demonstrated that the character of a pleural effusion must be ascertained before attempting to destroy adhesions with the thermocautery or otherwise When the effusion shows increased numbers of neutrophils the attempt had better be abandoned as the pleura is unable to cope with the bacteria released by the endopleural cauterization No other type of effusion forbids it He used Jacobæus' endoscope and thermocautery both introduced into the interpleural space inside a trocar Adhesions taken from seven cadavers showed no signs of large blood vessels or lung tissue, even in fibrous bands up to 1 cm thick In four of his ten cases the procedure was a success breaking up the adhesions and allowing complete pneumothorax In four other cases the adhesions were not thoroughly destroyed although clinically the procedure has been a success in one case and roentgenologically in all In two cases he failed to sever the adhesions A subcutaneous emphysema was a frequent complication and in three cases a serous effusion followed A broad fibrous band can be mobilized under thoracoscopy by extrapleural resection of the portion of rib to which the adhesion has grown This was done in one case with good effect releasing the collapsed lung from traction by the stout adhesion that fastened it to the wall of the chest

*Transplantation of Testes E Kreuter —p 538
*Median Prostatectomy J Oehler —p 540
Unsuccessful Trials with Alloplasty in Vascular Wounds H F O Haberland —p 542
Hexamethylenamin in Pyonephrosis H Harttung —p 543
*Dosimetry in Roentgentherapy K Fritsch —p 545
Gritti s Amputation F Bahr —p 546
*Resection of Bone to Remedy Finger Contracture Eckstein —p 547

Transplantation of Testes in Relation to Homosexuality—Kreuter relates his experience with the transplantation of half of a testis taken from a confirmed homosexual pervert in the prime of manhood It was implanted in a man who had undergone bilateral castration two years previously, but whose general health was good The patient was not aware of the origin of the testis implant The patient recovered normally from the operation Eight months later he expressed himself as "satisfied" with the results of the operation He has occasional erections, but insists that the penis is becoming constantly reduced in size His sexual instincts have remained heterosexual There is not the slightest indication of any homosexual effect resulting from the implantation, as might be expected from Lichtenstern's statement that he has cured homosexual patients of perverted sexual instincts by implantation of heterosexual testes Owing to such reports it has been concluded by some that sexual tendencies might be associated with certain cells of the interstitial gland Kreuter thinks his operation as above cited contradicts this theory In fact, he holds that the transplantation of testes with a view to incorporating a truly functioning endosecretory organ in man is scarcely justifiable As a suggestive measure it may, in some cases, accomplish something

Median Prostatectomy—Oehler states that the unfa[vorable] conditions for drainage after suprapubic prost[atectomy] induced him to try median prostatectomy as recon[structed] by Berndt and Praetorius in 1914 and 1918 and sin[ce] was pleased with the simple technic (which he descr[ibes] detail) and the unusually slight shock from the op[eration] Although the method has not as yet found general acce[ptance] among surgeons, Oehler thinks it certainly deserves [attention] by all The problem of gravity drainage of the pr[ostatic] cavity is solved by this method [with] most excellent resu[lts]

Present-Day Dosimetry in Roentgen Irradiation on Tumor Cells—Fritsch sets forth t[he] present-day dosimetry is based [on the fact] that tu[mor] cells are killed by roentgen rays [while] their ca[pacity] ity to multiply is destroyed, that [this] immediate effect on the tumor cel[l] however, would seem to indicate t[hat] upheld and that the effect of roentg[en] rays strengthen the local tiss[ue] dy set in against the action of [the] increase or accentuate the defense measures of the organism If this assumption should be confirmed, dosi[metry] must be put on an entirely different basis, for in that c[ase] it is not a question of killing the tumor cells but of di[rect]ing in each case the stimulation that is necessary in to secure the most favorable reaction It is not so statistics as it is serious research that is needed to solve t[he] problem, and thus give to roentgentherapy an es[sential] impetus

Shortening the Bone to Remedy Finger Contracture Eckstein during recent years, has given up trying by [operative] tive efforts to lengthen and mobilize the shrunken soft pa[rts] but endeavors instead to restore the normal proport[ion] between the bone and soft parts by resecting from t[he bone] of the first phalanx a piece of bone from 1 to 2 cm The operation is carried out under local anesthesia by incision alongside of the extensor tendon, and the result that the finger can then always be extended without difficul[ty] since the flexor tendon though impaired sufficed for t[he] purpose The cicatricial tissues of the flexor tendon assum[e] the function almost as well as if a normal tendon we[re] present He thinks the method might perhaps be applicab[le] to Dupuytren's contracture, although he has never tried himself

*Nucleic Acid in Puerperal Infection J Hofbauer —p 580

Prevention of Puerperal Fever—Ahlfeld reports t[hat] without using rubber gloves without employing rectal exam[ination] nation without restricting internal examinations w[ith]out omitting preliminary vaginal lavage, and although pati[ents] were continually examined by students they were able t[o] get excellent results from the standpoint of mortality fo[r] out of 8753 patients only one died of puerperal fever [after] preceding normal birth This one fatal case dou[btless] resulted from self-examination or evolved from an e[arlier] internal affection Ahlfeld gives this report to show [that] good results can be secured without resorting to the extre[me] precautions recommended by Doderlein

Treatment of Rectal Injuries After Radiotherapy—Kol[de] describes two cases of injury of the rectum from radioact[ive] treatment In one case there was ulceration in the rectum, in a second case a very large defect of the rectum with a fistula into the vagina To combat the rectal ulcer, he employed starch enemas with from 10 to 20 drops of opium, also diathermy the positive electrode in the vagina, the neg[a]tive over the sacrum Under this ambulant treatment, grad[u]al improvement was noticeable Organotherapy was also used The rectal ulcer healed but the patient still complai[ned] of weakness In the second case, after pursuing a waiti[ng] policy for so[me] time he at last constructed an artificia[l] anus in the [sig]moid The results were good and the pa[tient] covered her weight and strength Kolde [re]proaches h[im]self for that two years before, on appe[ar]ance of the [rectal] injuries he did not employ dia[ther]my to c[ombat] fibrosis secondly he admits that it [was] technic[ally] his par[t] at he did not do a sig[moid] omy [when] the f[irst] developed He would say [that] two years of illness and H such conditions not w institute curative

[Hofb]auer extols the [effect] The effect is [from] ary extracts
